Clinical Lecture
ON
TUBERCULAR PERITONITIS IN CHILDREN.

Delivered at St. Bartholomew's Hospital, Nov. 5th, 1880,

BY SAMUEL GEE, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—There are three kinds of tubercular abdominal disease occurring in children: chronic peritonitis, decay of the mesenteric glands, and ulceration of the intestines. These diseases are sometimes associated in different ways, sometimes they happen each alone by itself. They constitute a condition which the common people call "consumption of the bowels," although this term also includes the chronic enteritis which is not tubercular.

My topic to-day is tubercular peritonitis, or, what in the case of children is almost the same thing, chronic peritonitis.

I. PATHOGNOMONIC SIGNS.

They are discovered by physical examination of the abdomen, and are of two kinds: indurations and suppurations.

1. *Indurations* are detected by palpation. They have the form of bands and patches, or of lumps and knots. They certainly are present in most cases at some period or other of the disease. They begin to appear within a few weeks of the onset of the illness. They are more or less obscured by co-existing tympanites; and for this, or some other reason, they are not felt equally well at all times in the same patient. When the abdomen is very tender or resisting, I usually administer chloroform to the child before proceeding to the examination; and I strongly advise you to do the same thing in a doubtful case. The *bands* which I spoke of are commonly transverse, stretching right across the belly, or confined to one side of it. They are felt above the navel, on a level with the navel, or below it—for instance, parallel to Poupart's ligament. They are sometimes remarkably hard. They are mostly about the breadth of the finger, or rather more. The *patches* of induration, like the bands, may be met with anywhere; in a boy, now in the hospital, they are felt in the hypogastrium. The *lumps* and *knots* are sometimes very numerous, sometimes there are only one or two. Their size is very different, they often feel like nuts or pips. They differ very much in situation; there is no rule in these matters. The distinction (not always possible) between peritoneal and glandular lumps is to be found in the fact that the former are as a rule more superficial, less deeply seated than the latter.

2. *Suppuration.*—Discharge of pus from the navel, due to a local peritoneal abscess, is likewise characteristic. Sometimes there is nothing more than an appearance of pointing, which afterwards subsides, and never goes on to discharge. The navel looks red and swollen, not merely protruded, but its tissues swollen. This sign I believe to be no less characteristic. The pus is sometimes mixed with fæces. This is a condition which indicates ulceration of the intestine, and is a very much more dangerous affair than the discharge of pus alone.

Physical examination will also discover signs of either or both of two other abdominal lesions in most cases of tubercular peritonitis. *Tympanites* to a less or greater degree is a symptom almost always present at some period or other of the disease. *Ascites* is less common. In one case of this kind a diagnosis was made possible by the co-existence of phlegmonous scrofulides on the leg, otherwise there was nothing but ascites.

II. ONSET OF THE DISEASE.

Tubercular peritonitis is usually idiopathic, that is to say, it constitutes the disease in and by itself. This is the only case which I consider on the present occasion. I pass by the chronic peritonitis which is secondary to manifest tubercular disease of the lungs, intestines, or other parts.

1. The onset of protopathic tubercular peritonitis is mostly *gradual*. The belly becomes tender, painful, and large; at the same time the health of the child fails; there are emaciation, loss of appetite, and in many cases slight fever. At the beginning examination of the abdomen discovers nothing but more or less tympanites, sometimes associated with a little ascites. The tympanites usually remains moderate, but in some children it becomes excessive, so much so as to cause permanent dyspnœa. The ascites of the onset is small in quantity, and mostly goes away in a few weeks. Afterwards the indurations which I spoke of begin to appear.

2. The onset is sometimes *sudden*, and attended by very great tympanites. The tympanites is sometimes the only abdominal symptom. Sometimes it is associated with vomiting. And sometimes there are also all the signs of acute gastro-enteritis. In my lecture on tympanites last session I narrated a case of this kind—a child suddenly attacked by infantile cholera; violent vomiting and purging, with collapse, algidity, and tympanites. This was the beginning of chronic tubercular peritonitis.

III. COURSE OF THE DISEASE.

Suppose the chronic peritonitis established, you will most likely be able to detect one or other of the pathognomonic signs which I spoke of at the beginning. I will now speak of the symptoms which are attendant upon the confirmed disease. Emaciation from the first; appetite bad; vomiting now and then. Action of the bowels uncertain. Diarrhœa, occasional or even more continual, is no proof by itself of the co-existence of intestinal ulceration. Constipation is common, and it goes on in a few uncommon cases to absolute obstruction of the bowels. This obstruction is either temporary, giving way at length to the remedies employed, or it is permanent, and causes the death of the patient. The latter course is well illustrated by a case published by Dr. Wolston in the 10th vol. of the Clinical Society's Transactions. Obstruction of the bowels, although it may have been relieved, is apt to recur. Pain in the belly is sometimes severe, and is sometimes felt on heavy pressure only. The movements of the bowels are sometimes visible, whether there be much tympanites or not. Fever is present at first, but is seldom high; it often ceases altogether after a week or two; sometimes a low degree of fever is constant throughout the whole course of the disease. So that, at the time you see your patient, it may happen that there are no fever or other symptoms of disease, except the emaciation and the abdominal signs already spoken of.

IV. TERMINATION OF THE DISEASE.

1. *Recovery* from tubercular peritonitis is common. In the course of months, or a year or two, the tympanites disappears, and the indurations cease to be palpable. The patient is left pale and weak, and may continue so for the rest of life. On the other hand, he may regain his original state of health. The most positive proof of recovery from tubercular peritonitis is afforded by Mr. Spencer Wells' case,[1] in which the ascites of that disease resembled an ovarian cyst. Abdominal section was performed; the peritoneum was seen to swarm with tubercles; the intestines, for the most part, were adherent together. Acute peritonitis followed the operation, but the patient recovered, and six years afterwards she was stout, hearty, and well.

2. *Death* from tubercular peritonitis occurs in several ways. A slow exhaustion is common, especially when other forms of tubercular disease come to complicate the case. Increasing and great ascites may be the cause of death. You remember a girl who died in Mary ward after paracentesis for ascites? In her, tubercular peritonitis was associated with highly-marked cirrhosis of the liver, and this is a combination of lesions which I have seen before. Obstruction of the bowels is an uncommon cause of death.

When suppuration has occurred there is an additional danger. Mere pointing sometimes goes away without any manifest discharge of pus from the navel or any other part. When actual discharge of pus from the navel has occurred recovery is still possible. But when there are signs of a fistulous opening into the bowel the case is hopeless, as I said before.

V. THERAPEUTICS.

The first thing to mind, in the treatment of tubercular peritonitis, is to keep the abdomen at rest. This can be done only by keeping the patient in bed. I have known a boy, who was slowly recovering whilst he was in bed, undergo a fatal relapse of his disease by being taken up and dressed against orders.

Another part of the treatment consists in putting a flannel bandage round the belly, so as to reach from the hips to the ribs. Much pain in the abdomen is alleviated by hot and moist fomentations, as hot as the patient can bear; linseed meal poultices, flannel fomentations, or, what is usually best, a flannel bag full of bran or camomile flowers, which can be heated in hot water or an oven as often as needful. You may sprinkle the fomentation with laudanum; or you may smear the abdomen with a liniment composed of equal parts of extract of belladonna and glycerine.

---

[1] Quoted by Dr. Fagge, Guy's Hospital Reports, third series, vol. xx., p. 203.

I need not say much about the necessity of allowing none but the most easily-digestible kinds of food; in short, to feed the patient very much as you would feed a baby. Cod-liver oil, if it can be taken, is sure to do good.

For the ascites you may try copaiba resin cautiously, beginning with three or four grains, made into an emulsion, with an equal quantity of compound tragacanth or almond powder, and some water. If this mixture disagree with the stomach you must discontinue it.

When suppuration has set in the proper treatment is assiduous poulticing.

Introductory Lecture

ON THE

CLINICAL STUDY OF THE DISEASES OF THE EYE.

Delivered at University College Hospital on Thursday, October 7th, 1880,

BY WHARTON JONES, F.R.C.S., F.R.S.,

PROFESSOR OF OPHTHALMIC MEDICINE AND SURGERY IN UNIVERSITY COLLEGE, AND OPHTHALMIC SURGEON TO THE HOSPITAL.

GENTLEMEN,—If you take the pains to examine for yourselves the cases which come under treatment in the Ophthalmic Department of the hospital, and watch their progress, you will soon learn to recognise the principal forms of eye disease and the remedies employed for them. The study of the diseases of the eye by the practical observation of cases is comparatively an easy task, soon comes to be interesting, and is sure to prove successful. But without the aid of such means of study, the attempt to become acquainted with the nature and treatment of eye diseases is painful and laborious, and in the end unsuccessful. May what I now say be an encouragement and inducement to you to bestow some attention to the clinical study of the diseases of the eye, while you have the opportunity of frequenting the ophthalmic department of the hospital. If, however, you do not accept it as hint sufficient to incline you to do so, let what I am going to say be taken as a warning against the neglect of it.

You are not likely to be long engaged in practice before meeting with a case of the purulent ophthalmia of new-born infants. Now, this disease, if seen in time and properly treated, may, in the large majority of cases, be completely cured; whereas, if it is not properly treated, it is liable to run on to the damage of the cornea, if not destruction of that important part of the eye, with irremediable blindness.

The proper treatment is simple; nothing, indeed, more simple. But picture to yourselves the position of a young practitioner who helplessly witnesses the eyes of his infant patient running on to destruction, and remembers that he never took the trouble when a student of the hospital to prepare himself for such an emergency by lending a hand in the manipulations necessary in the treatment of cases of ophthalmia neonatorum.

You will observe that the diagnosis is obvious, and that, as regards treatment, it depends merely on the practical tact you can bring to bear in the application of the local remedies whether you shall be successful or unsuccessful in curing your case.

Of the liquids which you will see dropped into the eyes of our patients, a solution of the nitrate of silver and a solution of the sulphate of atropia are those in most common use. The nitrate of silver solution—five or ten grains to the ounce—is one of the most efficacious applications in inflammations of the conjunctiva, though, let me remark, it is not the sole remedy at our command, for other irritating substances do nearly, if not quite, as well. Besides the drops which we apply ourselves at the hospital, we give the patients weaker solutions to use at home as lotions. The atropia lotion which we give is of the strength of one grain to eight ounces. We never give a nitrate of silver lotion. We give a weak solution of some other irritant, such as the bichloride of mercury of the strength of one grain to eight ounces, or alum, sixteen grains to eight ounces. The reason we do not entrust the patient with a nitrate of silver solution is that when its use is injudiciously prolonged, as it is liable to be under the circumstances, the conjunctiva becomes dyed by it of a dirty-olive hue. Though you will see the nitrate of silver or other irritating solution dropped into the eye in cases of inflammation of the conjunctiva, you will never see it dropped into the eye in cases of iritis or other internal inflammations of the eyeball, for in such cases irritating collyria do more ill than good. In cases of iritis you will see the solution of the sulphate of atropia dropped into the eye, not, however, with the expectation of subduing the inflammation of the iris, such as we have of subduing the inflammation of the conjunctiva when we drop the nitrate of silver solution into the eye in a case of catarrhal conjunctivitis. The principal object we have in view, when we drop the atropia solution into the eye in a case of iritis, is to counteract, as far as possible, the strong tendency which the pupil has, in the course of that inflammation, to become contracted.

But how are we to distinguish between conjunctivitis and iritis, you may perhaps desire to ask, in order to know when to drop in the nitrate of silver solution and when to abstain, but to drop in the atropia solution? My answer to such a question would be in the words with which I commenced this lecture, viz.:—"If you take the pains to examine for yourselves the cases which come under treatment in the ophthalmic department of the hospital and watch their progress, you will soon learn to recognise the principal forms of eye disease and the remedies employed for them." If you will but study clinically the nature and treatment of the purulent ophthalmia of new-born infants, catarrhal conjunctivitis, scrofulous ophthalmia, and iritis, you will find in the knowledge you thereby acquire of these forms of eye disease a foundation on which you may at leisure successfully erect the superstructure of whatever else the exigencies of practice may render it necessary for you to know respecting ophthalmic medicine and surgery.

At the Eye Infirmary you will have the opportunity of seeing performed the various operations on the eye. But let me observe that though it is of great importance that you should witness the operations, it is also of great importance for you to watch the progress of the case after the operation; and of equally great importance, moreover, it is to have examined the case before operation, and made yourselves acquainted with its pathology and the reasons for operating. Every now and then patients present themselves with injury of the eye of various degrees of severity, ranging from the case in which there is merely complaint that something has got into the eye to cases in which there is an actual wound, even smash of the eyeball. In the case in which something is in the eye, the foreign particle you will usually see discovered adhering to or embedded in the cornea; and if not there, you will most probably see it discovered on everting the upper eyelid adhering to the palpebral conjunctiva. In a case in which there is a wound or smash of the eyeball, it may be that you will see us cut out the whole damaged organ at once. One principal reason for performing this operation of enucleating the eyeball is to guard the other eyeball as far as possible from the risk of becoming affected with destructive sympathetic ophthalmitis, to which there is a great liability under the circumstances.

By even a short attendance at the Eye Infirmary the various points I have now touched on will become familiar in your mouths as household words, so that you will be able to understand what I may have to say more in detail in subsequent clinical lectures. Until a few years ago crowds of ear patients used to invade the ophthalmic department of the hospital. In commiseration I did not turn them away, though they necessarily cost me much additional labour. Of late, however, Mr. Barker has undertaken the task of looking after such cases. But the truth is, we cannot altogether exclude cases of disease of the ear from our attention at the Eye Infirmary, even if we would, because ophthalmic patients are often found to be at the same time labouring under some affection of the ears—for example, in children with scrofulous ophthalmia there is often chronic inflammation of the membrana tympani, with discharge from the ears. The most remarkable example of a connexion of disease of the ears with disease of the eyes is the supervention, in cases of keratitis or kerato-iritis from congenital syphilitic taint, of inflammation of the membrana tympani and lining membrane of the cavity of the tympanum with sometimes inflammation of the labyrinth attended by great and obstinate deafness.

In a large proportion of cases diseases of the ear are not very amenable to treatment—not by any means so amenable to treatment as diseases of the eye; but still there are some in which, when the disease is taken in time and treated on sound principles, much may be done for the patient's benefit.

In the course of practice you will often be called upon to attend a case of earache, for example. This means, pathologically speaking, acute inflammation of the membrana tympani. Now, in such a case you may quickly subdue the inflammation, relieve the patient from the excruciating pain he is suffering, and save him, perhaps, from subsequent confirmed deafness. The treatment from which such a very desirable result may be obtained is similar to that which you will see so beneficial in analogous cases of eye disease—viz., leeches behind the ear, hydrarg. c. creta and belladonna powders, with warm fomentations.

Last session I gave a special clinical lecture for the purpose of showing how the pathology and treatment of the diseases of the ear may be elucidated by a reference to our better knowledge of the pathology and treatment of the diseases of the eye. The lecture was printed in THE LANCET, Oct. 25th, 1879, p. 601, and I beg to refer you to it.

ABSTRACT OF

The Brown Lectures.

FURTHER INVESTIGATIONS ON ANTHRAX AND ALLIED DISEASES IN MAN AND ANIMALS.

BY PROF. W. S. GREENFIELD, M.D., F.R.C.P.

LECTURE II.

IN undertaking experiments with the view of preparing an artificial virus of anthrax, which whilst capable of affording sufficient protection on inoculation should not manifest such severity in its action as to endanger the life of the animal inoculated, Dr. Greenfield had, in common with many others working at the same subject, believed that so long as the anthrax bacillus maintained its morphological characters, and ordinary powers and mode of growth, it would still preserve the power of producing the disease on inoculation. He therefore sought to maintain a supply of the virus by artificial means rather than by the continuous inoculation of animals; the cultivation method employed being that in tubes partially filled with an albuminous fluid, preferably in aqueous humour. He soon found that these cultivations, though apparently identical in characters and mode of growth, were not of equal potency, and could not constantly be relied upon to produce the desired result. This was not due to admixture of other organisms or failure in the cultivation; and observations were made to determine, if possible, to what cause this deterioration was due, and whether there was any actual diminution in the potency of the virus in successive generations, and if without impairing the vitality of the bacillus its disease-producing power could be gradually abated. Cultivations of the anthrax bacillus direct from the blood of a guinea-pig which had died of the disease were repeatedly made through several generations, and each successive cultivation was submitted to rigorous microscopical and other tests. In this way cultivations were made up to twenty-five generations without any difference being detected in the mode of growth, or the morphological characters of the organism; the regular steps of growth and formation of spores taking place with the greatest regularity as to character and time, the sole perceptible difference consisting in the greater freedom of growth as the successive cultivations proceeded. The following is a summary of the results observed in rodent animals inoculated with the successive cultivations made in this way. With the first, second, and third cultivations the effects are almost, if not quite, as severe and fatal as in a direct inoculation from one animal (guinea-pig or mouse) dead of anthrax into another. It is from about the fourth cultivation that diminished virulence is first perceived, the effects being slower and less certain, although usually fatal sooner or later, and in the case of the fifth cultivation death may not occur for one hundred hours; between the sixth and eighth the result, even with an increased quantity, is less certain, and in some cases the material proves innocuous. From this point onwards the toxic effect is but little marked, sometimes considerable quantities being used with impunity. The latest period at which results were obtained was with the fourteenth cultivation, and then only in mice, and with marked differences in the condition produced from that seen with the earlier cultivations. Having described the results of some of the experiments illustrating the above statements, Dr. Greenfield said that some peculiar effects were observed with some of these inoculations—viz., the production of much slower death, apparently by a sort of chronic anthrax poisoning, with the presence of bacilli only in certain parts, especially in the lungs and pleural serum—a fact of importance in reference to woolsorters' disease.

The results in bovine animals (see Lecture I.) are strictly analogous with those obtained upon rodents, allowing for the greater power of resistance of bovine animals to the virus. No symptoms were produced with any cultivation later than the fourth, whilst in every case marked effects occurred in animals not previously inoculated when the first, second, or third cultivations were used. Moreover, the effect of inoculation with actively growing cultivations of the generations later than the seventh, was practically *nil*, and did not confer any appreciable degree of protection upon the animal so inoculated. It must be noted that in bovine animals there is not only a greater power of resistance, but also a varying degree of relative insusceptibility.

As to the possible contamination of the cultivations by other organisms, he remarked that in his later experiments he had rarely noted the presence of any other organisms, though of course they might be accidentally introduced. Of the organisms which might gain admittance micrococci were by far the commonest; bacterium termo had been only once observed. But wherever other organisms were present, they would not only be discovered by the tests to which each tube was submitted, but in the case of micrococci the changes produced in the fluid were often visible with the naked eye, owing to the opalescence they produced. Whenever other organisms were detected, the tube was thrown away and other pure tubes used. But had it not been so, further pure cultivations would not have been attained unless the micrococci had died out, although their presence does not prevent all growth of the bacilli. Further (as would be shown by microscopic specimens and photographs), great care was taken to obtain evidence that in their physical characters there was no real diversity between the bacilli of the earlier and those of the later cultivations; and it would be absurd to suppose that in every one of the numberless instances there should be invariably introduced, at a particular stage of the cultivation, another bacillus identical with the anthrax bacillus, which it entirely displaced; whilst in no cultivation of other bacteria did it ever show itself. He wished, however, to guard against the possible misconception that because the results found in this particular method were such as described they would therefore necessarily be the same with other cultivation methods and the use of other quantities of the material for inoculation. Buchner's experiments show beyond doubt that the virulence is longer maintained when the cultivations are made in meat infusion, and possibly in other fluids it may be still longer. And larger quantities of material inoculated may possibly produce more marked effects. Indeed, the poison may be readily intensified in the living body. If an animal dies of anthrax of modified form and slow course, and another be inoculated from it, the latter usually dies more rapidly, and the next in succession still more rapidly, so that by cultivation in the animal body the maximum potency of the virus may be speedily regained.

Dr. Greenfield then proceeded to discuss the remarkable experiments made by Dr. Hans Buchner at Munich, and lately brought under the notice of the profession in England by Professor Lister, and the bearing they had upon the relation of the anthrax bacillus and the bacillus of hay infusion, and of his ultimate success in causing the hay bacillus to grow in the blood until he obtained by inoculation of a considerable quantity of the material a disease analogous to anthrax with bacilli in the spleen and blood; that it could be inoculated upon other animals, and with each become more virulent until typical rapidly fatal anthrax was induced.

The late investigations of M. Pasteur upon "fowl cholera" were next considered. Fowl cholera is widely prevalent in France, highly fatal, consisting in a form of blood-poisoning, probably not arising from direct contagion, but by means of the excreta of diseased birds becoming mixed with the food, and inoculation through the alimentary canal. It has no analogy with human cholera, and probably is only one of a number of fatal epidemic diseases of this class among poultry. Its dependence upon a microphyte belonging to the class of micrococci was discovered by M. Perrencito of Turin, and subsequently investigated by MM. Pasteur and Toussaint. M. Pasteur announced to the Académie des Sciences that he had succeeded in cultivating the organism in neutral urine, and in decoction of fowl's muscle, and that by a peculiar method he had obtained it in the form of an attenuated virus, which if inoculated into fowls rendered them insusceptible of the effects of the most deadly virus. M. Toussaint by many experiments endeavoured to prove the identity between fowl cholera and septicæmia; but although suggestive of a close relation between the two diseases, Dr. Greenfield did not think them conclusive in establishing their identity.

M. Pasteur found that cultivations of the organism forming the virus of this disease decreased in potency the longer they were kept, if in contact with pure air, the rapidity of death being lessened and the disease remaining more local, the longer the interval between the time of inoculation and the time at which the cultivation of the virus was commenced. He pointed out that these changes occur in a very variable manner, some cultivations becoming greatly attenuated after three or four months; others much longer; and sometimes the parasite dies. There is no morphological difference to be seen between the less and the more virulent condition of the bacterium. If cultivations are made at short intervals of time of each successive virulence each maintains its own degree of intensity, and an interval which will kill a more attenuated virulence will only modify the more intensely virulent. He attributes this modification to the slow action of oxygen on the parasite; for if the tubes containing the virus and cultivating liquid be hermetically sealed, the virus will develop in proportion to the quantity of oxygen contained in the tube, and will retain its original virulence for long periods; but if the cultivation be exposed freely to the air there is a gradual diminution, even to extinction, of the strength of the virus.

But, Dr. Greenfield asked, may not these results be due to vital phenomena rather than external influences? When the access of free oxygen is prevented, the growth of the bacteria is continued to a certain period, at which the oxygen is exhausted; it then remains (in the case of bacillus anthracis with formation of spores) quiescent, the fluid having undergone hardly any chemical change. If new oxygen is supplied, fresh growth will occur. On the other hand, when there is free access of oxygen from the first, all the pabulum can be exhausted by the successive growth of the fungus, which continues to multiply until its food-supply is gone. It has thus no longer the power of forming a healthy and well-developed brood which can remain quiescent until called upon for further activity, but either destroys itself in the process, or is vitally deteriorated. In the resting stage probably the vital changes in the organism are very slow. Again, bacteria in their growth not merely produce chemical change in the fluids in which they develop, rendering them alkaline, but a certain quantity of a material prejudicial to their own life is also generated. And an exhaustive overgrowth of the bacteria must generate a larger quantity of this substance, which may in the presence of oxygen lead to further chemical changes in the fluid. Apart from this, the conditions of growth in the two cases are, as regards the vital activity of the fungus, totally distinct, and this difference should be borne in mind in estimating the result on its future condition.

Dr. Greenfield is, then, inclined to attribute these modifications to conditions which are common to the whole cycle of plant life rather than to mere chemical action, a view substantiated by other facts. For whether the action of the pathogenic bacteria be regarded as dependent upon some virus excreted by them in their growth, or upon some direct influence exerted by them, all analogy warrants the belief that these are largely governed by the vital activity of the organism and the soil and surroundings which condition its growth. Thus may be explained the differences observed in the results of cultivations in various media, as well as the effects when inoculated. If an organism be grown in any particular medium for a certain number of generations it must become more or less habituated to the medium, and it is not strange that on its transference to another medium it will not take an active growth until it is rehabituated to it; and conversely, when growth in any particular medium is well established, it can often be carried on with far greater ease in successive generations than at first; it is, in fact, acclimatised.

These facts, then, instead of militating against the view that the bacillus is the essential virus of anthrax, or the micrococcus that of fowl cholera, are strongly in favour of it, for they show that the condition of disease-production is the power of healthy and active growth of the parasite in the body, and the conditions which lessen or prevent the disease those which impede or check that growth, and the aim should be to modify the parasite by cultivation rather than allow it to fall into decadence or death from a sort of wilful neglect.

In conclusion, Dr. Greenfield described the methods of cultivation adopted by various observers, and exhibited various forms of apparatus used for the purpose.

ON THE ACTIONS AND USE OF CERTAIN REMEDIES EMPLOYED IN BRONCHITIS AND PHTHISIS.[1]

BY T. LAUDER BRUNTON, M.D., F.R.S.

IN both bronchitis and phthisis the first symptoms that attract notice are cough and expectoration, and the first remedies that claim our attention are the so-called sedatives and expectorants. Cough consists in deep inspiration, closure of the glottis, and violent expiratory effort, by which the glottis is forcibly opened by the compressed air, which carries with it, in its exit, mucus or other matters which may have lodged in the lungs or respiratory passages. The nervous centre for this act lies in the medulla oblongata. It is bilateral, and situated on each side of the central raphe. It is excited into action reflexly by irritation of the respiratory branches of the vagus distributed to the glosso-epiglottidean folds, to the whole interior of the larynx, to the trachea, especially at its bifurcation, and to the bronchi, and the substance of the lung itself, as well as the pleura when it is inflamed. Irritation of the internal auditory meatus at the point to which the auricular branch of the vagus is distributed also causes coughing, and so also may irritation of the liver and of the spleen. As coughing is a reflex act, excited by irritation applied to a sensory nerve, and reacting through a nerve centre upon the respiratory muscles, it is obvious that it may be lessened, either by removing the source of irritation or by diminishing the excitability of the nervous mechanism through which it acts. Both methods are employed in medicine. One of the commonest is that of lessening irritation by the use of glutinous and saccharine substances. These have in themselves little or no action upon the nervous mechanism. They do not pass down to the bronchi, or lung substance, so that they can have no direct effect upon the mucous membrane there, nor have they, so far as we know, any effect upon them after they have been absorbed into the blood; and yet one of the commonest observations is that glutinous and saccharine substances have a very great power to allay cough when applied to the back of the throat, even in cases where we know that inflammation and consequent irritation exist in the respiratory passages below the glottis, at a point which the mucilaginous substances cannot reach. The probable explanation of this action of such substances as marshmallow lozenges, jujubes, consisting of gum and sugar and Spanish liquorice, is that the irritation which occasions the cough exists at the root of the tongue and around the fauces, as well as in the trachea, bronchi, or lungs, the combined irritation rendering the cough worse than either the one or the other alone would do; and, therefore, if we soothe the tongue and fauces we relieve the cough, even though the irritation in the bronchial tubes or lung may remain as before. The power of such substances as those mentioned to relieve cough depends, no doubt, to a great extent either on their covering the inflamed and irritable surface directly with a mucilaginous coat, and thus protecting it from the action of the air or from irritation by other substances passing over it, or by exciting an increased flow of saliva or mucus, which has a similar effect. At the same time we cannot deny the possibility of their having other actions, though with these we are at present unacquainted. The use of the mucilaginous substances containing opium or other sedatives, which we know under the name of "linctus," is a more complicated one. In them we have the soothing action of the mucilaginous compound, combined with the local sedative action of morphia, chloroform, or hydrocyanic acid upon the inflamed or irritable mucous surfaces at the root of the tongue and back of the throat, and this renders even their local action more powerful than that of a mucilaginous substance alone. Such drugs as opium, hydrocyanic acid, and chloroform have a certain amount of local action upon the peripheral ends of sensory nerves, and lessen their sensibility to impressions. When they are applied to the ends of the nerves only for a very short time, as they are when we swallow these drugs in a liquid form, their local action is comparatively slight. It is much greater when they are taken in a mucilaginous vehicle, which, adhering to the irritated mucous membrane over which it passes, keeps the sedatives in contact with it for a longer time, and thus allows them to exert a more powerful action. But the sedatives which we give to relieve cough are not unfrequently administered in the form of solution, and then, though their local action must be comparatively slight, they still lessen a troublesome cough. Their action here is a different one from that which we have just discussed, but it is possessed by the sedative whether given in the form of linctus or of solution. In either way it is swallowed by the patient, absorbed from the stomach and intestines into the circulation, and carried by the blood to the medulla oblongata, and also to the inflamed mucous membranes, in which the blood circulates freely, just as well as in other parts of the body, although here its action is likely to be very much less than if it were applied for a length of time directly, as in the shape of the linctus; but, as we have mentioned, the linctus can only be applied to the back of the tongue and throat, and the source of irritation of the afferent nerves may be in the bronchi or in the lung itself. Here, no doubt, a linctus cannot penetrate, but we may to a certain extent act locally upon the nerves by the use of spray and inhalation. Some of these, such as the vapour of conium and the vapour of hydrocyanic acid, are intended to lessen the irritability of the sensory nerves in the respiratory passages, and thus lessen cough. Others, such as the spray of ipecacuanha, and inhalation of essential oils and terebinthinous substances, have probably a different action, and do not lessen the irritability of the sensory nerves in the respiratory passages, but alter the nutrition of the mucous membrane in such a way as to diminish the irritation which the abnormal condition of the membrane exerts upon the nerves. When the irritation is situated in the larynx, as in cases of laryngeal phthisis, one of the best means of relieving it is by applying the sedatives locally, whether by means of a brush, or, what is perhaps still better, by blowing it, in the form of a powder, directly upon the irritated surface. A useful application in laryngeal phthisis consists of a mixture of morphia and starch, in the proportion of about one-sixth of a grain of morphia to two grains of starch. This mixture is introduced into a glass tube, of a proper shape, and is blown down the throat at the instant that the patient takes a deep inspiration. The powder is thus distributed over the interior of the larynx, and exerts its local sedative influence upon the irritated surface, as well as a general sedative effect upon the central nervous system after its absorption.

---

[1] Read before the Medical Society of London, Dec. 19th, 1880.

This brings us to the second mode in which sedatives relieve cough. After their absorption into the blood, in whatever manner they may have been applied, they are carried to the medulla, and there lessen the excitability of the nerve centre through which the reflex act of coughing is produced. In large doses their sedative effect may be so great as to endanger life, and the caution is given in every text-book, and by every teacher, that respiratory sedatives such as opium should be carefully administered to persons suffering from bronchitis with profuse expectoration, lest the irritability of the medulla should be so far diminished that it will no longer respond even to a powerful stimulus from the lungs, and the secretion may consequently go on accumulating until when the patient awakes the respiratory passages are so clogged with mucus that no effort which he can make is sufficient to clear them, and he dies of suffocation. By administering them in smaller quantities, however, the effect of respiratory sedatives may be graduated so as to diminish cough without any risk of causing death, and their effect would be exceedingly beneficial if they acted only upon the respiratory centre. Unluckily, however, this is not the case, and the most powerful of all—viz., opium—not only influences the respiration, but the digestion. It diminishes the cough, but sometimes, also, it diminishes the appetite, and may interfere with the proper action of the bowels. When this is the case, we are obliged carefully to steer between two dangers: (1) the injurious effects of the cough itself, and (2) the injurious effect of disturbed digestion. If we leave the cough alone, it exhausts the patient, for the muscular exertion involved in a violent fit of coughing is very considerable indeed, and the muscular effort exerted by a patient with a bad cough during the twenty-four hours is really more than equivalent to that of many a man in a day's work. Nor is this all. Anyone who watches the face of a patient during a violent fit of coughing will see the skin become flushed, and then dusky; the veins in the forehead and in the jugulars swell up, and become so tense that they seem as if about to burst; so that there is both venous engorgement and interference with the respiration. But what we see in the face takes place elsewhere. The same tension which we see in the jugulars is also present in the right side of the heart, in the vena cava, and in the portal system; for the portal vein has no valves, and the increased tension is transmitted backwards to the veins of the stomach, spleen, and intestines. By-and-by this all begins to tell upon the heart and upon the digestive system, as well as, to some extent, upon the kidneys. The stomach becomes congested, and we have loss of appetite, nausea, and vomiting. The patient, too, is kept awake, and we have nervous exhaustion, or loss of sleep, added to the weariness caused by the muscular exertion, and to the depression occasioned by digestive disturbance. These are what we have to fear: on the one hand, continuous coughing; on the other, we must avoid the digestive disturbance produced by our sedatives; and the duty of the physician is, so far as possible, to relieve the cough without disturbing the digestion. Numerous combinations have been devised, and are found to be, empirically, of very great service. If we take one of them and attempt to analyse it, we shall find that its components are such as to diminish the excitability of the respiratory centre, and at the same time to lessen the injurious effect of the sedatives upon the stomach. Such a one is the following mixture:—Solution of hydrochloride of morphia and dilute hydrocyanic acid, of each eighteen minims; spirit of chloroform and dilute nitric acid, of each one fluid drachm; glycerine, three fluid drachms; infusion of cascarilla or infusion of quassia, two fluid ounces: a sixth part to be taken three or four times a day.

In this mixture, which in its essence was much used by the late Dr. Warburton Begbie of Edinburgh, to relieve the cough in phthisis, we find the sedatives morphia, hydrocyanic acid, and chloroform, to lessen the excitability of the respiratory centre; we find glycerine, which will tend to retain the sedatives for a longer time in contact with the back of the throat, and will also act to some extent as a nutrient. We have combined with these nitric acid and infusion of cascarilla or of quassia, which have so-called tonic (?) action upon the stomach. In what this effect precisely consists we cannot at present say, but we may imagine that it will in some way partially counteract the effects of the congestion which the cough produces, and at the same time we know that they have the power of exciting appetite, and they will thus in a great measure counterbalance the injurious effects of the morphia upon digestion. Nor is this all, the nitric acid, as I shall shortly have to mention, has a very definite effect indeed upon the secretion in the lungs themselves; and this brings us to the consideration of another part of our subject—viz., the effect of drugs upon the secretion and nutrition of the lungs, by which they tend to restore the healthy condition of the bronchial and pulmonary tissues, and thus diminish coughing.

First of all, then, we must consider those drugs which lessen congestion. If a person, hastily eating or drinking, gets a crumb of bread or a drop of fluid down the larynx, or into the wrong throat, as it is termed, he suddenly begins to cough violently, and the cough continues until the source of irritation has been removed. If the irritation has been violent he may give a few coughs after the crumb has been coughed up, although the primary source of irritation—namely, the crumb—has disappeared; but the congestion which it occasions still remains for a short time, and acts as an irritant. If a person suffering from disease of the mitral valve makes any sudden exertion he is very likely to bring on a cough, which, however, quickly subsides after a short rest. The cough here is not due to inflammation of the mucous membrane, but simply to congestion, and when the congestion disappears the irritation goes with it. In cases where we have inflammation of the respiratory vessels actually present, as in persons suffering from bronchitis, the congested condition of the membrane is a source of considerable irritation, and we frequently notice that such persons, on going out into the cold air, may cease to cough, but again begin to cough violently when they return from the cold air into the warm room. The reason of this is that the cold air has acted upon the congested vessels of the respiratory passages in a somewhat similar way to what it does upon the vessels of the face; it causes them to contract, and the congestion being thus diminished the cough is lessened. When the patient goes into the warm room the face, which may have been pale while he was exposed to cold, flushes up with the heat, the vessels of the respiratory passages also become engorged, and the increased congestion causes irritation, bringing on the cough. In other cases, again, we notice that, just as the face becomes pale when exposed to cold, it shortly afterwards becomes flushed, although the application to cold continues. A person suffering from bronchitis, on going into a cold room, will begin to cough violently, the cold here increasing instead of diminishing congestion.

The pulmonary capillaries have great contractile power. Ten years ago I made some experiments, which I have not yet published, on the subject. I found that on the application of cold to the lung of a frog, when placed under the microscope, the capillaries would contract to two-thirds of their former diameter. We have, however, very few observations on the action of drugs upon the pulmonary circulation, the difficulties in the operative procedure being very considerable. I have observed that muscarin appears to have a power of contracting the pulmonary vessels, and that this effect is abolished by atropia. I am unaware, at present, of any other observations on the action of drugs upon the pulmonary circulation. Circumstances have prevented me from studying the recent researches on this subject in the way I should have wished, while drawing up this paper. From its power of contracting the vessels in other parts of the body, we should expect that digitalis would have a similar action upon the lungs; and we find, in looking over Beasley's "Book of Prescriptions," that digitalis has been used in pulmonary affections—as for example, in the following draught, employed by Sir A. Crichton in acute phthisis: lemon-juice, half an ounce; carbonate of potash, to saturation; decoction of sarsaparilla, ten drachms; tincture of digitalis, ten to thirty minims; acacia mucilage, ten drachms: to be taken every sixth hour. In such a prescription as this we have the tincture of digitalis, which will, in all probability, by contracting the vessels, diminish the pulmonary congestion and lessen cough. It is combined with carbonate of potash, and the effect of potash upon the lungs is very marked indeed. For my knowledge of its action I am indebted to Dr. Andrew Clark. Its action is perhaps best noticed in a patient suffering from consolidation and softening of a limited portion of one lung. When such a patient is in ordinary health, one may observe, on a stethoscopic examination, crepitant râles, limited to one spot. When he catches cold, one may hear, in addition to those, dry râles extending for some distance around the irritated spot, and the cough at the same time becomes more frequent and troublesome, while there is very little, if any, expectoration. If potash be now given alone, or, still better, in combination with a vegetable acid, the dry râles subside, and are replaced by moist ones, which in the course of a day or wo, as the potash is continued, alter in character, giving one the impression of their being caused by less viscid fluid. At the same time the expectoration becomes more copious, and the cough less frequent and less troublesome. Now is the time to alter the treatment, and for the potash to substitute nitric acid. If this be given too soon the cough, which had begun to get easier, will again become drier and harder, but if it be administered at the proper moment the cough becomes still less troublesome, the expectoration diminishes, and the moist râles disappear from the neighbourhood of the consolidated part of the lung, although they may still remain, as before, in that part itself. Potash, then, has a very marked effect in rendering the pulmonary secretion more fluid and abundant, while nitric acid has an opposite effect. As in many cases we wish to diminish the secretion rather than increase it, it is nitric acid rather than alkalies which we employ for long periods in the treatment of phthisis, as we have already seen in the modified formula of Dr. Begbie's phthisis mixture.

One of the most powerful expectorants is simply a little warm food in the stomach, and in cases of chronic bronchitis, in which the patients complain of violent coughing immediately after rising, one of the best expectorants is a glass of warm milk, either with or without a little rum, and a biscuit or a piece of bread about a quarter of an hour before they get up. A little warm beef-tea will have a similar effect. After taking this for a short time they generally tell you that the sputum comes away much more easily than before, and they are not so much exhausted by it. But perhaps the remedy, *par excellence*, not only in cases of phthisis, but in chronic bronchitis, is cod-liver oil. Persons suffering from long-standing chronic bronchitis will often come to a hospital to beg for cod-liver oil, saying that it eases their cough far more than any cough mixture. Other oils or fats have not this power to the same extent as cod-liver oil. We cannot say positively what the reason of this may be, but I think there is no doubt about the fact. My own belief is that cod-liver oil is more easily assimilated than other oils, and not only so, but more easily transformed into tissues themselves. Whether it owes this property to its admixture with biliary substances, or to its chemical composition, we cannot say. In his book on "Fat and Blood, and how to make them," Dr. Weir Mitchell quotes a remark made by an old nurse, that "some fats are fast, and some fats are fleeting, but cod-liver oil fat is soon wasted." By this she meant that there were differences in the kinds of fat accumulated under the subcutaneous tissues of men, just as there are differences in subcutaneous fats which accumulate in horses. The horse fed on grass soon gets thin by hard work, while fat laid on when the horse is feeding on hay and corn is much more permanent. Persons fattened on cod-liver oil soon lose the fatness again, and this, I think, points to the power of ready transformation which the oil possesses. Supposing that it does possess this power we can readily see how very advantageous it will be. In chronic bronchitis, and in catarrh and pneumonia, we have a rapid cell-growth, but want of development. The cells lining the respiratory cavities are produced in great numbers, but they do not grow as they ought to do. They remain, more or less, lymphoid cells, instead of developing into proper epithelium. They so rapidly form, and are thrown off so quickly, that they have not time to get proper nutriment, and if they are to grow properly we must supply them, not with an ordinary kind of nutriment, but with one which is much more rapidly absorbed, and is capable of much more rapid transformation in the cell itself than the usual one. This power is, I believe, possessed by cod-liver oil, and to its quality of nourishing the rapidly-formed cells in the lungs in cases of bronchitis and catarrhal pneumonia I believe its great curative power is owing.

The next subject we will consider is the action of some drugs in the vomiting associated with cough. The action of vomiting, like that of coughing, is reflex; the nervous centre for it is also in the medulla oblongata, closely associated with the respiratory centre, and it is excited by various afferent nerves, the chief of them being the branches of the vagus distributed to the stomach. When congestion of the stomach is present, these become irritated, and we get loss of appetite, nausea, and vomiting. Like coughing, vomiting may be prevented by the removal of the irritant. For example, where the irritant is indigestible food, the vomiting ceases after the ejection of the offending substances. When the irritation depends on inflammation of the walls of the stomach, it may be soothed by sedatives having a local action upon the nerves, such as ice and hydrocyanic acid, or by drugs having the power of lessening the irritability of the nerve centre of the medulla, such as opium. In the chronic vomiting of phthisis, all these drugs may be employed, but there is one other which has been useful in this affection, and which probably has no effect either upon the nerve centre or the nerve ends. This is alum. Its mode of action probably is that by its astringent power it contracts the vessels of the stomach, and thus lessens the congestion and consequent irritation produced by the continued coughing in the manner already described.

GASTROSTOMY; ESTABLISHMENT OF A GASTRIC FISTULA, IN A CASE OF STRICTURE OF THE ŒSOPHAGUS.

By GEORGE BUCHANAN,
PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF GLASGOW.

(*From notes by* J. L. STEVEN, M.B., *and* J. K. LOVE, M.B., *House-Surgeons in the Glasgow Western Infirmary.*)

THE following case is worthy of record; for although the patient died in a fortnight of inanition, the operation itself was performed with succees, the patient recovered from the effects of it, the wound healed, and a perfect gastric fistula was established.

The stomach, from long disuse, seemed to have lost much of its digestive and absorbent powers, so that the fluid nourishment which was introduced and retained failed to strengthen the patient. Whether an earlier resort to the operation might have enabled the man to live longer is difficult to say. But the case is another illustration of the fact that an opening can be made with safety into the stomach through the abominal walls.

Wm. B——, aged sixty, a porter, was admitted into Ward III. of the Western Infirmary on Sept. 10th, 1880, complaining of symptoms pointing to obstruction of the œsophagus. His family and personal history, apart from the present illness, are remarkably good. The symptoms above alluded to began in the month of February, 1880, with difficulty in the swallowing of solid food. Gradually this difficulty increased till, in the month of June, he was unable to swallow such substances as oatmeal porridge. For some time after this his diet consisted chiefly of porridge made with pea-meal. Soon, however, nothing but liquids could pass, and his diet was chiefly milk and beef-tea. On admission not even fluids could be swallowed, any attempt in that direction being followed by their regurgitation in a few minutes, or sometimes less, in a frothy condition. During all these months he had been getting steadily thinner, and on admission was very considerably emaciated. At no time was pain or dyspnœa a feature of the case; indeed, apart from the inability to swallow, he made no complaint but of weakness. Dr. Buchanan failed to pass a probang and œsophageal bougie, both of which stuck about half-way down the œsophagus.

No exact weight of patient was taken on admission, but it was evident that, notwithstanding the continued use of nutrient enemata, he was rapidly emaciating. These enemata were commenced on Sept. 20th. His weight on Oct. 16th was 7 st. 5 lb.; on Oct. 18th, 7 st. 2¾ lb. The emaciation continuing, Dr. Buchanan decided to operate, and on Oct. 27th gastrostomy was performed.

The operation.—An incision one and a half inches in length was made across the linea semilunaris, about an inch below and parallel to the eighth left costal cartilage. The tissues were divided down to the peritoneum and the cavity of the abdomen opened. The transverse colon was now exposed to view at the lower part of the wound. On the introduction of a pair of forceps in search of the stomach, the anterior wall of that organ was seen on withdrawing the instrument to have been grasped, and the gastro-epiploica artery on the greater curvature, two inches below the part, was seen to be held up. Through the part of the stomach wall thus brought to the opening two acupressure needles were thrust at a distance of one and a half inches apart, and, having been passed through the organ, were again thrust through the wall, and the ends made to rest on opposite sides of the wound. The stomach was now carefully stitched by ten carbolised silk sutures to the edges of the wound, and an incision about an inch in length made through the wall of the organ, between the rows of stitches, with a pair of scissors. A smaller transverse incision was now made, and the resulting corners secured to the lips of the wound in the abdominal wall by stitches. The operation, which had been performed under the spray, now being completed, a large acupressure needle was pushed through a long indiarubber tube, about three inches from one end. This end was then introduced into the stomach, while the ends of the needle rested on the thoracic and abdominal walls. The tube was fixed in this position by lateral strings. The long end of the tube was bent downwards and the wound dressed with antiseptic precautions, drainage being secured by the open tube leading from the stomach. During the three days immediately following the operation the tube was used for drainage purposes, and a small quantity of brownish bilious fluid was collected.

No symptoms due to the operation can be said to have followed, unless perhaps a slight rise of temperature. The maximum temperature did not, however, now exceed 100° F. There was no pain, and no tympanites or other symptom of local or general peritonitis. For a day or two after the operation he was fed entirely by enemata of beef-tea and brandy (usually four or five in the twenty-four hours). On the 30th of October (the fourth day), previous to which the wound had been dressed on antiseptic principles, the dressings were taken off, and the drainage function of the tube changed into a nutritive one, half an ounce of milk and a drachm of brandy being introduced into the stomach. This was continued every two hours during this and the following day, after which the amount introduced was increased gradually, while the intervals of digestion were lengthened till on the 4th of November twelve to fifteen ounces of brandy and milk were introduced in four or five meals during the twenty-four hours.

On the 6th the tube was taken out permanently, and the mouth in the stomach closed by a pad of boracic lint, kept in position by two or three strips of sticking-plaster, the whole being removed when anything was introduced into the stomach by a syringe. On the same day twenty-six ounces of brandy and milk were introduced, and on the two succeeding days this was replaced in part by beef-tea, peptonised fluids, &c.

During all this time, although no untoward symptom had occurred, it was evident that emaciation was progressing in spite of the continued enemata and the feeding by the stomach. The sensations of the patient varied from day to day, but on the whole tended to those of slowly increasing weakness. Occasionally he wandered a little at night; sometimes he was morose, complaining, and easily annoyed, sometimes happy and hopeful in his expressions. On the 7th it became evident that he was losing strength quickly, and rapidly emaciating; and on the 8th of November, the thirteenth day from the date of operation, he died of asthenia, having been sensible to within an hour of his death.

The edges of the wound in the abdominal wall were united to the opening in the stomach within a few days of the operation, so that on removing and replacing the tube there was no tendency to separation of the edges, except at the inner angle, where there was a small slough of the subcutaneous cellular tissue. But this did not extend into the abdomen, the peritoneal surfaces of the stomach and abdominal walls having become adherent very early.

In a post-mortem examination it was found that there was a small oval tumour encircling the œsophagus about two inches and a half above the cardiac orifice of the stomach. The œsophagus passed through the centre of this swelling and was contracted for an inch of its length, so that a probe was with difficulty passed through it, even after the partial softening of the mucous membrane, which occurs soon after death. The upper orifice of this structure was plugged with a grape seed, of which the smaller end was downwards, so that it was fixed like a stopper in a decanter. The tumour was tough and firm, and its intimate structure was that of epithelial cancer.

Glasgow.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES.

Mr. James Bentley, late of Cheshunt, bequeathed £1000 to St. Bartholomew's Hospital (of which institution he was formerly treasurer), and £100 to the Samaritan Fund, £500 to the Seamen's Hospital, £200 to St. Thomas's Hospital, and £100 to St. Luke's Hospital for Lunatics. Mr. T. E. Price, late of Stoke Newington, bequeathed £100 each to King's College and the Royal Free Hospitals.

THE SIMULATION OF SOMNAMBULISM.[1]

BY CHARLES RICHET, M.D. PARIS.

Is it possible, by having recourse to magnetic passes, by the fixed gaze, or analogous processes, to literally send people to sleep? In my opinion this question is completely answered. It is not so, however, with a large number of enlightened physicians and *savants*, who decline to admit the reality of facts which I regard as incontrovertible. In such a matter they say we have only to do with dupes or their accomplices, charlatans, who trade on public credulity, with simple observers who allow themselves to be abused by trickery, with hysterical girls who deceive and who simulate without any other motives than love of deception and simulation. Sometimes a few condescend to recognise that there may be some truth at the bottom of it. But this truth is so small that it is not really worth the trouble of talking about.

However, the number of sceptics is daily diminishing. During the past year especially very many works have appeared which have dispelled many convictions. But with a scientific fact it is not a question of convincing a few persons; everybody must be convinced. Thus it is necessary, before studying somnambulism, to scrupulously examine the proofs of its reality. Is it an illusion or a verity? Must we seriously accept what *savants* have told us about it, or scoff at their extreme simplicity?

Scientific certainty consists in this:—That the phenomenon observed can be reproduced at will by all those who shall proceed in the same manner as the first observer. Thus, when a chemist declares that chlorine in passing into potash results in the formation of chloride and chlorate of potassium, there is no need to repeat this experiment to be sure that it is the truth. If he who has discovered this reaction be ever so little experienced his word will be believed, certain that a repetition of the experiment will lead to the same result. It is just the same in mathematics, in physics, and to a certain extent in physiology; and proof is obtained by this fact only that it is known one can reproduce at will the same phenomenon under identical conditions. But with somnambulism it is otherwise. I declare, for example, that in making the "passes" for ten minutes over the forehead and head of a young man twenty-five years old I have sent him into a state of somnambulism, and that I have been able to observe in him contracture, catalepsy, hallucinations, &c. It does not follow, however, that another physician acting in the same manner on another young man will, in his turn, see the same phenomena reproduced. It is, on the contrary, very probable that the same result will not be obtained; for somnambulism occurring as in the first experiment is, in man, a very exceptional thing.

It is, therefore, necessary, in demonstrating the reality of facts which are not reproduced as often as one wishes, and which are in themselves so surprising, to seek for proofs which may carry with them, if not certainty, at least conviction. We may have either an absolute nullifying pathognomonic proof, or a collection of proofs, which, taken together, are equivalent to rigid and irrefutable demonstrations.

Now, it is impossible to produce absolute proof. An individual appears to be asleep. Whether he be more or less analagesic, more or less anæsthetic, matters little, they say, since, on the one hand, it is easy to simulate these two symptoms, and, on the other, they are far from being constant in somnambulism. If these modifications of sensibility be taken as absolute criteria, one would be almost certainly led to declare subjects hypnotised who, perhaps, are not so; and, on the other hand, to accuse of bad faith certain persons who are really hypnotised. The closed eyes, the jerking movements of the eyeballs, the fibrillar movements of the eyelids, contractions, hallucinations—all this it is certainly possible to simulate. Who can say that certain hysterics do not practise these manœuvres, with no other motive than the desire of deceiving the physician?

There is then no absolute sign, or rather there is only one, which, however, it is difficult to obtain, and which can only convince a single person—it is, to hypnotise her oneself, and to make her tell on waking, in the presence of trusty witnesses, the recital of the acts she has accomplished during her sleep, and of which the memory has escaped her thought. I have twice employed this measure, once in the case of Miss C——, and a second time with my friend F——. Miss C——, after having been present at an experiment, told me that she was not at all sure of the good faith of the hypnotised person. "What do you see extraordinary in it?" she said. "She has been able to simulate sleep perfectly. I cannot believe in somnambulism until you have sent me to sleep." I proposed to try the experiment on her; she accepted; and at the end of ten minutes was asleep. On awaking, and in spite of my affirmations and the assertions of her friend, Mdlle. D——, who, like her, is studying medicine, she would not believe in her own somnambulism, and almost accused me of having administered a soporific draught. However, she was forced to submit to the evidence, especially on looking at her watch, and on learning that what to her had appeared a minute had lasted an hour and a half. To sum up, there is no absolute irrefutable proof of somnambulism; a person can only be convinced by being himself hypnotised.

Unfortunately this method is not very practicable, and for many reasons; among others because *savants* whom it would be desirous to persuade would be very bad *magnetic* subjects. Besides, one could thus only convince a single person at once. We must therefore have recourse to other arguments.

First, the chief is the absurdity of supposing that all hypnotised persons have simulated sleep. For my part this supposition appears more than ridiculous. Here, for example, are two of my intimate friends, educated and enlightened young people, in whom I have absolute confidence. Must I admit that they have deceived me and have made sport of me? I could not be so unjust to five or six honourable individuals, whom I did not know, as to suspect them of bad faith for anything in the world. Besides, I should then have to believe that the fifty individuals, or thereabouts, of all ages and conditions, whom I have been able to hypnotise, were all without exception, *without a single exception*, knaves and liars. That would indeed be most absurd. The eminent professor of physiology at Breslau, M. H. Heidenhain, relates that he has been able to hypnotise his young brother, a distinguished student at the university. Can one admit that this young man has been acting so as to treacherously abuse the simplicity of his brother, and to make him a vulgar laughing-stock? It will be seen further on that nearly all women are, more or less, susceptible of being hypnotised. That would signify that nearly all women consent to feign sleep. Frankly is such a supposition admissible? Could not one woman be found to refuse this imposture? Two alternatives present themselves, and one is forced to recognise them: either all women are knaves and dissimulators, or somnambulism is a real fact. It will be granted, I think, that the former of these two hypotheses is manifestly absurd.

Second, another consideration should be invoked—viz., the agreement between the phenomena. The facts seen by Luysegur, Deleuze, Husson in France, sixty years ago, were observed by Braid in England about 1840; in Paris in 1860 by M. Broca; by myself in 1875; by M. Charcot and M. P. Richer in 1877; by M. Heidenhain, at Breslau, in 1880; and by so many other *savants*, during a century, in all Europe, that I could not quote all their names. That would be a very strange simulation to be reproduced so often in so long a time, with the same appearances—closed eyelids, fibrillar movements in the muscles of the face, hallucinations of vision and hearing, catalepsy, contracture. How is it that women coming from the country, having never heard the word magnetism pronounced, could simulate that of which they were ignorant? By what divination could a patient, whom I hypnotised at the Charité, and who had never witnessed any somnambulism, behave herself absolutely like a patient at the Beaujon Hospital, who came from the provinces, and whom I hypnotised the very day of her admission? That is a marvellous fact, quite as marvellous as the wonderful phenomena obtained by the professional magnetisers. On one view it should all be simulation, and the first dissimulator (the little peasant Victor, hypnotised about 1800 by M. de Luysegur) having set the fashion of a certain kind of sleep, all the other subjects, whom we believe to have been hypnotised, would only have imitated the fantasy of this little impostor?[2]

---

[1] By "somnambulism" the author means "hypnotism." In order to avoid confusion the term "hypnotise" has been used for "endormir" throughout this article, although the author never employs the former word

Third, let us suppose even that there is fraud, and examine if this supposition can be made to accord with facts. I think I can affirm the contrary; for simulation, as it would be practised, must suppose a profound knowledge of anatomy and physiology. M. Charcot insists strongly on this fact, that if the nerves be pressed the muscles supplied by them contract, at least in certain somnambulists. Thus, by pressure on the facial nerve, the zygomatic muscle and the levators of the lip are made to contract. By exciting the sterno-mastoid muscle it is made to contract; the head then turns to the opposite side. Now, it must require a considerable knowledge of the physiology of movement to know that the sterno-mastoid, in contracting, turns the head to the opposite side. With somnambulists one can by direct incitation cause contraction of the muscles (rudimentary in man) moving the auricle of the ear. Now, this contraction is impossible in the individual when awake. By opening the right eye, one provokes a catalepsy of the right side, in consequence of the double decussation of the optic nerves and the cord. In another hysteric, by opening the right eye aphasia was produced; whilst by opening the left eye no such effect was obtained. Certainly, if this be simulation, one must assume that the patient knows that speech is affected by the left cerebral hemisphere, and that the retina of the right eye is in relation with this hemisphere, whilst the right hemisphere is useless for speech.

All those who have seen hysterical contractures during somnambulism are satisfied that these disorders of the muscular system are not simulated. There is no individual strong enough to preserve voluntarily the contraction of a muscle during a quarter of an hour without one perceiving in it the slightest tendency to weakness or relaxation. Now, the somnambulists maintain their contractures for many hours, and on waking they have no recollection of, no fatigue from, this prolonged and improbable effort. As to the so-called passion-attitudes, when the different emotions of the soul are expressed with an unheard-of fervour, I doubt very much if there be in the world an actor so good as to perform these mimicries with such success as the poor hysterical girls of the Salpêtrière. All somnambulists behave thus; their mimicry is so expressive, their sentiments of ecstasy, of love, admiration, anger, disgust, scorn, menace, are expressed with so striking a vigour, that all those who have witnessed them are convinced that there is no room for simulation.

(To be concluded.)

---

[2] Some time ago, when travelling in Algeria, preoccupied with seeking for a proof of the reality of somnambulism, I tried to hypnotise an Arab woman of the negro village of Biskra (an officer, a friend of mine, who knew the Arab tongue, served as interpreter). In a few minutes this woman, feeling her eyelids grow heavy, said to her stupefied companion, "My eyes are closing." "Say, 'By Allah,'" the other advised. "By Allah, my eyes are closing." And, in fact, she soon went to sleep, to the great surprise of all present. Must the influence of the little Victor be involved in this case also? At the hospital of La Pitié I have only made one experiment, and I guarded myself against any cause of simulation. The patient on whom I experimented did not know what I wished to do. I told her that I would galvanise her for a disease of the knee from which she was suffering, and, in fact, I had a galvanic battery near the bed. This battery, which the patient thought very active, did not act; yet the patient experienced such somnolence and lassitude that she was forced to close her eyes. As I did not wish to make the "passes," I could not obtain complete sleep; but many times I succeeded in producing very manifest somnolence.

SALICYLIC SILK AS A SURGICAL DRESSING.

By A. F. McGILL, F.R.C.S.,

SURGEON TO THE LEEDS PUBLIC DISPENSARY.

THE time has now passed when it is either necessary or expedient to discuss the antiseptic treatment of wounds. The success of the treatment is generally admitted by those surgeons who have given it a fair trial, and many are only deterred from using the Lister dressing by the supposed extra trouble which it entails. Any plan, therefore, which we can adopt whereby the practice may be simplified while the principle remains unaffected cannot but aid in leading to the more general adoption of antiseptic surgery.

When a wound of considerable size is dressed antiseptically in the usual manner with carbolic gauze, the dressing must of necessity be changed several times during the first week. If this is not done, the serous discharge, which exudes in large quantity, soaks to the outside. Putrefactive changes ensue, and the case, as it is generally called, "breaks down." The frequent changing of the dressing in the early days after the infliction of a wound, during the time that healing by first intention may be expected, is an unmixed evil. It is probably owing to this cause that immediate healing of wounds treated antiseptically is not of more frequent occurrence. The handling of a wound at a later period when primary adhesions have become firm, or when granulation has occurred, is a matter of little moment. Unfortunately it happens that disturbance is necessitated at the very time when rest is most imperatively needed. If, then, we can use as a dressing some material which will not require to be renewed except at long intervals, we not only increase the patient's chance of a speedy recovery, but lessen very considerably the work and expense of the surgeon. Such a material is, I think, found in salicylic silk. The silk used is the article called in the trade "silk noils." These noils are a waste product, and are consequently of comparatively small value; they are sold for stuffing cushions and chair bottoms. The silk is soaked in a solution of salicylic acid, made by dissolving the acid in methylated spirit and boiling water. After soaking and drying ten parts of the silk should weigh eleven; consequently the silk when ready for use contains 10 per cent. of the acid.[1] Before using it is advisable to tease the fibres asunder; though this is not absolutely necessary, it considerably improves the dressing, making it softer and more absorbent. At the same time its bulk is much increased, and consequently a smaller quantity is required for a dressing. When the silk is adopted as a dressing no antiseptic precautions should be neglected, the carbolic-acid spray and lotion being used in the usual manner. For drainage in large operations I have been in the habit of using the ordinary india-rubber tubes, either wholly or partially removing them at the end of the first week; in smaller wounds, tubes of decalcified bone, catgut threads or fiddlestrings, prepared antiseptically and twisted into a spiral, have been inserted. These last, which are in suitable cases very efficacious, were first suggested and made by my friend Mr. G. D. Todd, a former house-surgeon at the Leeds Public Dispensary; being made of an absorbent material, they possess the advantage that they do not require any change of dressing for the purpose of removal. All absorbent tubes have, however, a common fault—they are not efficient in cases where they are exposed to the pressure of heavy flaps, as any considerable pressure causes them to collapse prematurely. The dressing is usually applied direct to the wound; in some cases where there has been a long incision, a strip of thin muslin or gauze soaked in carbolic lotion has been first applied, covering all the wound except the points where the drainage-tube has presented; over this, silk in large quantities has been lightly bandaged. Wherever the silk has touched the wound it has been usual to dip a small portion in carbolic lotion before applying it. This has been done in deference to Professor Lister's teaching—to destroy any putrefactive germs which might alight with impunity on the non-volatile salicylic acid; but, as any liquid which reaches the germ would at the same time reach and dissolve the acid, it seems improbable that any putrefactive changes would result if this precaution were neglected.

The first dressing applied as directed above is not disturbed for from five to ten days, unless the condition of the patient necessitates an examination of the wound. If the temperature remains above 100° Fahr. it is probable that drainage is interfered with, and an examination of the wound is called for. If, however, proper care has been taken at the first dressing, such an examination will rarely have to take place. The second dressing may be left on for an indefinite time, and will not usually be removed till the wound is entirely or almost entirely healed. I need hardly add that all dressings are changed under the spray. The following cases are fairly typical of many others which have occurred in my practice.

Amputation of Leg.—A woman, aged fifty-seven, had suffered from an ulcer of the left leg for many years; the ulcer extended all round the limb; it had been healed on several occasions, but the cicatrix always broke down a few weeks after leaving bed. The patient was a fat, flabby woman, who had partaken freely of spirits. I amputated below the knee, making a long posterior flap; two large india-rubber drainage-tubes were inserted, the limb was covered with salicylic silk, and bandaged on to a piece of Gouche's splinting. On the sixth day the dressing was removed. On the fifteenth day the stump was again examined, and found entirely healed. The patient's temperature reached 99·2° on the second day, but was never afterwards as high as 99°.

---

[1] It is manufactured by Messrs. Harvey & Reynolds, Leeds. Mr. Reynolds, to whom I am much obliged for the trouble he has taken in the matter, has recently added one ounce of glycerine to each pound of silk. This fixes the acid, and prevents it from shaking out and causing unpleasant sneezing.

Removal of Mamma.—The patient, aged fifty-one, was suffering from a scirrhus of the left breast, accompanied by enlargement of the lymphatic glands in the axilla. The breast was of large size, and the operation an extensive one of its kind. The silk dressing was applied in the usual manner. The first dressing was on the fifth day, when half the drainage-tube was removed. The second dressing on the tenth day was necessary to enable us to remove the remainder of the tube. The wound was all healed, except where the tube had prevented union. The third dressing was on the twenty-first day, when the healing was complete. The temperature reached 100·5° on the second day; by the third day it was below 99°, and never reached it again.

Ligature of the Femoral Artery for Popliteal Aneurism.—An ordinary straightforward case in a man, aged thirty-nine. The aneurism was a small one which had only been discovered a week before operation. The artery was tied with carbolised silk; drainage was insured by the use of three strands of catgut; catgut sutures were used. At the first dressing on the eighth day the wound was healed with the exception of a small superficial sore a quarter of an inch in diameter, situated at the point where the catgut threads emerged. The dressing was reapplied and removed on the fifteenth day, when cicatrisation was complete.

In estimating the value of the new dressing it can be compared (1st) with carbolic gauze, and (2nd) with the salicylic cotton-wool used by Professor Thiersch. Compared with carbolic gauze: (1) It requires less frequent renewal, thereby saving the patient pain and discomfort, and the surgeon time. (2) It increases the chance of a speedy union of the wound by insuring rest in the early days of treatment. (3) It will keep for an indefinite time, whereas the gauze after the lapse of a few months loses its antiseptic properties. (4) It is cheap, and consequently saves the surgeon and patient expense. Compared with the salicylic cotton-wool it is found to possess two great advantages: it is more absorbent and more elastic. Its absorbing properties make it a much safer antiseptic; its elasticity prevents it from caking, and makes it more comfortable.

Leeds.

ADDITIONAL NOTES ON

FILARIA SANGUINIS HOMINIS AND FILARIA DISEASE.

By PATRICK MANSON, M.D.

I REVERT to this subject in continuation of a paper of mine which appeared in last year's *Customs Gazette* in order to bring forward some evidence lately obtained corroborating unmistakably my conjectures as to the habitat of the parent filaria. Those who have followed these investigations will remember that, reasoning from the position in which I found in certain cases the ova and embryos of the parasite, I concluded that the parent worm lived in the lymphatic trunks. The following are my notes of a case in which I found the mature parasite *in situ*, and in the place conjectured. The parent worm has been found by Bancroft in Australia, Lewis in India, Aranjo in Brazil, but this is the first time, as far as I know, in which it has been possible to state precisely from direct observation the particular structures it occupied. I therefore think the observation of sufficient value to justify its publication.

CASE 57. *Lymph scrotum, filaria embryos in lymph from scrotum, but not in the blood; excision of parts of the scrotum; parent filaria in dilated lymphatic.*—P. M——, aged forty-six, a pedlar and farmer. Four or five years ago he noticed that after much walking he had pain in both groins along the course of the spermatic cords, but he says it was never or very seldom associated with fever. He says he has never had inflammation nor abscess of the scrotum. At first there was swelling of and pain in the groin lymphatics, but on the bursting of a vesicle which had formed on the scrotum, and the escape of much fluid, these subsided. During the first year or two scrotal discharges occurred only once or twice a year; then they became more frequent, and during the last three months the discharge has been nearly constant. It may stop for a day or two occasionally, but as a rule the scrotum drips lymph night and day, perhaps to the extent of ten to fifteen ounces in the twenty-four hours. The discharge, he says, is always clear, like water, and when collected in a bowl, coagulum with red particles and streaks forms rapidly. Has never had chyluria nor any serious illness. He is very thin and anæmic, but, though much debilitated, is in fairly good health.

Oct. 11th, 1880.—Inguino-femoral glands on both sides enlarged, especially those on the right side; they are neither distinctly varicose nor firmly indurated, but have a soft spongy feel. The bulk of the scrotum is only slightly increased, but everywhere on its dusky red-brown surface are scattered innumerable minute vesicles, varying in size from a No. 6 to a No. 2 shot. Pricking any of these permits the escape of a clear watery fluid. As I examine the scrotum, this fluid, oozing from some ruptured vesicles, drips constantly. The right testicle is absent, probably undescended; there is no hydrocele on the other, which feels large and healthy. The under surface of the sheath of the penis is somewhat swollen, but is not vesiculated. The scrotum feels soft and silky. There is no elephantiasis or swelling of the legs. The clear watery nature of the lymph is peculiar. I found, in a short examination of sediment of some drawn at 11 A.M. to-day, one embryo filaria. I collected two other specimens of lymph—one drawn between 4 and 5 P.M., the other at 7 P.M., and stood the three specimens to await resolution of coagulum. Blood drawn from the finger at 7.45 P.M. had no filariæ. I again, at 8 P.M., examined a large slide an inch and a half by one inch, but found no filariæ. The blood is very watery, and defective in corpuscles.

12th.—Examined the sediment of the three specimens of lymph—viz., that drawn yesterday at 11 A.M., at 5 P.M., and at 7 P.M., and found embryo filariæ in all of them, two or three in every slide of sediment. It is evident from this that the filariæ observe no periodicity while they are in the lymph, and that reproduction is a continuous process.

In this case, I believe, the obstruction in the lymphatic circulation of the scrotum is very low down, probably not higher than the inguino-femoral glands, and that it is complete. Because: (1) Had the lymph regurgitated after passing through the glands it would be milky or sanguineous, and be much richer in corpuscles than it is. (2) It is clear and watery, as it is near the radicles of the lymphatics. (3) There is an absence of marked varicosity of the lymphatic glands it first reaches; were the obstruction higher up the lymph circulation these lower glands would be distended by accumulating lymph. (4) Filaria in lymph, but not in blood—proving that the obstruction is complete. I think it probable, considering these facts, that the parent worm is between the surface of the scrotum and the first lymphatic glands, and that we will find it when the scrotum is excised. (This was written before the operation.)

13th.—Removed part of the scrotum this forenoon, the dripping of lymph continuing, and thought it advisable to operate to save the man's life. As he lay on the operating table under chloroform, I could see the anterior border of the spleen bulging out the relaxed and wasted abdominal muscles, and could feel that the organ was very much enlarged. Under such circumstances I generally abstain from all serious operations, but when I remembered the corpuscles and watery state of the blood, the absence of a history of malarial fever, the usual cause of splenic tumour here, the probability that it was the result of the state of the blood, and that this again was caused by the constant day and night dripping of lymph from the scrotum, I determined to proceed. The operation was a very simple affair. I dragged down the affected portion of the scrotum till it was clear of the testicle; transfixed the fold thus formed with a finger-knife; cut upwards and then downwards, removing a circle of about two and a half to three inches in diameter of soft, spongy, watery scrotum. Only three arteries required ligature. Pressing with the palm of the hand over the right inguino-femoral glands, I forced from an enlarged lymphatic on the upper and right corner of the wound a stream of lymph the thickness of a fine knitting-needle, and with a projection of three to four inches. The lymph thus expressed was clear and watery. I failed to do the same on the left side. The solitary testicle, the left, was healthy. The edges of the wound were brought together with catgut sutures. The scrotum when excised had been placed in a clean bowl, and when the operation was finished, I took it up and carefully examined the cut surface. Finding nothing unusual, I folded it up, intending to examine it at my leisure. However, being curious about my prognostication, I took it up again, and unfolding and exposing the cut surface saw wriggling on it very vigorously a long and slender worm of a catgut opaline look, the thickness of a medium-sized horsehair. One end of the worm was free, the other entered the cut end of the lymphatic corresponding to that from which I expressed the lymph on the right side. About two inches of the worm were free. I tried to coax out the rest with my finger, but failed. The worm appeared to be working back again into the scrotum. Fearing it would succeed in this, and also being afraid to crush it with the forceps, I laid it on the handle of a scalpel when it had partly dried and adhered. I made gentle traction, but the worm snapping in the vessel, I procured only about two inches of the free extremity, with long pieces of uterine tubes and alimentary canal dangling from the transverse fracture of the integuments. I did not attempt any further examination of the scrotum (which contains the caudal end of the female, and probably the male worm), but placed it in spirits and sent it to England. Dr. Bennett, of H.M.S. *Swinger*, was present, and assisted at the operation and saw the worm.

The same evening I examined with the microscope that part of the worm I had broken off. It was the head end of a female. The body was quite plain, without any markings, and tapered rather abruptly to the simple, somewhat club-shaped, mouth. The vagina opened about 1-25″ from the mouth. Uterus was packed with embryos in different stages of development. In the lower part of the uterine tubes the embryos lay at full length, outstretched, as we see them in the blood, and the sheath was very distinct in one embryo that had escaped from the vagina. This particular worm was certainly not oviparous. The following are my measurements carefully made:—Greatest diameter of body, 1-125″; diameter of alimentary canal, 1-900″; diameter of head at shoulder, 1-450″; orifice of vagina from mouth, 1-25″; diameter of body at vagina, 1-125″; ova before differentiation of embryo cleavage complete, 1-650″ × 1-850″; ova after differentiation of embryo, 1-590″ × 1-700″; diameter of uterine tubes, 1-200″; free embryo, 1-95″ × 1-3000″; length of sheath visible beyond the head of free embryo, 1-1400″. The animal was mounted in urine of a specific gravity similar to that of lymph, for examination. In such a medium the parts retain their natural proportions. If mounted in water, glycerine, or spirits, there is often much distortion, and an incorrect idea of relative and actual size produced.

15th.—Doing well. A slide of blood drawn from the finger at 5.30 P.M. contained no filariæ.

16th.—One slide of blood drawn at 5.30 A.M. contained no filariæ.

26th.—Had an attack of fever yesterday, and is still hot. The sheath of the penis is considerably swollen, but otherwise the case is doing well; the wound is granulating kindly, and there has been no escape of lymph since the operation.

Nov. 3.—Wound nearly healed; swelling of penis subsided. Patient, who has been taking large quantities of iron, much stronger; spleen smaller; blood still very defective in corpuscles; one slide drawn at 4 P.M. contained no filariæ.

6th.—Wound healed; no filariæ in the blood; going home to-morrow.

Amoy.

ON Wednesday last Princess Christian opened a new Cottage Hospital on Englefield Green, near Egham. The hospital has been built to accommodate eight adult patients and six children, and has cost about £2500, the whole of which has been raised by the residents in the neighbourhood, the Queen having been a very liberal subscriber to the funds.

THE EFFECTS OF THE INDUCED CURRENT UPON PARTURITION.

BY WALTER J. KILNER, B.A., M.B. CANTAB.,
ELECTRICIAN TO ST. THOMAS'S HOSPITAL.

IT is not an uncommon occurrence to meet with cases of confinements in which it seems likely that the child will be born in a few minutes, and yet there is a delay owing to the pains being very short, feeble, and at long intervals, although the mother shows no sign of fatigue. In these instances ergot might be of use, but it is not administered because it is expected that before it has time to act the labour would be over. Having met with three similar cases almost consecutively, I came to the conclusion that electricity might be of use, and I think that the results of my observations may interest some of the profession, as I am unable to find any mention of the induced current being used in parturition, except for the purpose of controlling post-partum hæmorrhage.

My first experiments were especially directed to discover whether the pregnant uterus, like the voluntary muscles, possesses *motor points*. After many trials, the conclusion I arrived at is that motor points exist, and can be easily found by bisecting the line drawn from the umbilicus to the middle of Poupart's ligament. This point is approximate, being only applicable before the uterus has descended, to allow the head of the child to enter the pelvis, and the spot varies slightly in each case according to the position of the uterus. When we talk of motor points, we must recollect that the uterine muscular fibres are of the unstriped variety, and that they do not respond to galvanic stimulation so quickly as the striped muscles.

When the poles of the coil are placed upon the spots just indicated the first thing observed is the immediate contraction of the abdominal muscles, the intensity of which depends upon the strength of the current. Occasionally, at the instant of contact uterine contractions commence, but more often a lapse of about a quarter of a minute is required, and not unfrequently they are delayed for two or three minutes. But still the current is taking effect, as the intermittent use, for instance, half a minute on and the same off, rarely fails to induce contractions in a few minutes; these increasing gradually in severity and duration while the intermissions become less and less. Latterly, however, I have applied the current only during the contraction, to obtain the benefit of the relief of pain. The following is a well-marked instance of galvanism producing uterine action:—

CASE 1.—Mrs. A——, aged twenty-nine. Third confinement, Oct. 1879. At 9.30 P.M. the os was very nearly dilated. The membranes were thick, and the child's head was in the first position. The pains were weak, and at intervals of rather more than ten minutes. The membranes were ruptured, and the terminals of the induction coil were placed one upon either side upon the motor points, and the current was only turned on during the pains. After she had three the pains became almost incessant, and they never ceased until the current was stopped. Although the contractions were violent she did not feel them so acutely as before the coil was applied. The child was soon born, and under the influence of the current the placenta was expelled forcibly outside the vulva. She had an excellent getting up, having very few after-pains.

The above case illustrates another frequent occurrence—namely, that *the pains do not cease until the current be discontinued*, but however more frequently, although the pains become very prolonged, yet they stop of their own accord. If it be wished merely to prolong any one uterine contraction, the current is best applied near the termination of the pain, when it will commence *de novo*. In one instance, which will be directly related in full, the induced current did not produce any uterine contractions, although the abdominal muscles did so violently.

CASE 2.—Mrs. B——, aged thirty. First confinement, June, 1879. Labour pains commenced yesterday soon after midnight. This afternoon at four o'clock the os was about the size of a crown piece, and very rigid. I administered an injection of hot water for six or seven minutes, during which time the pains were severe, and in ten minutes from the commencement of the injection the os was fully dilated. Subsequently the head did not advance further than the lower part of the pelvis, and remained stationary although the pains were strong for three or four hours. About this time the pulse rose to 120 per minute in the intervals, and higher during the pains. I was then allowed to use the coil, and applied a gentle current to the abdomen, avoiding the motor points during the pains. The contractions of the uterus, which were previously every three or four minutes, increased in number to one about every thirty seconds. The most singular effect, however, was that the pulse rate during the interruption after the first pain, during which the current was used, declined to eighty per minute, and for twenty minutes the pulse did not rise above that number. Besides *during* the second pain the pulse fell to sixty beats per minute; subsequently the pulse did not vary either during or between the pains. After twenty minutes it rose to a hundred, and as I came to the conclusion that mechanical interference was necessary, I applied the forceps and delivered her. Another striking effect was that before the current was used the woman was very fatigued and worn out, and every pain tried her much, but immediately upon the application of the galvanism the careworn expression vanished, and the subsequent pains were not so trying, although she still felt them, but not so severely. Mother and child went on well.

CASE 3.—Mrs. C——, third confinement, July, 1879. Soon after midnight, when I saw her for the first time, the os was half dilated. Cranial presentation, first position. The pains had commenced at about 3 o'clock on the previous afternoon, and there was about five minutes interval between them. At 4 A.M. I was called again, the os was nearly dilated. The pains had become very slight, and soon disappeared entirely. Pulse 140. She looked worn out, and complained of faintness, which was the reason I was called. As there was no obstruction I gave a dose of ergot, and applied the coil. Neither had the slightest effect of producing uterine contractions, although the abdominal muscles responded freely. In less than half a minute the pulse rate was lowered to 108, and all the sense of fatigue disappeared. As all the bad symptoms were arrested, I gave her a sedative. Eighteen hours afterwards the pains commenced again spontaneously, and the child was born at 10.40. The placenta was, as in previous labours, entirely adherent. She had a good getting up.

The first consideration we will take will be that of the sensation of pain. In Case 1 this was almost entirely removed by the current, while in Case 2 it was lessened, and in other instances not quoted it continued more or less severe. As we find that the induced current has such a variable effect upon the pain during labour, we think it is impossible to ascribe the whole of it to the sensation caused by uterine contraction, and we think there is another factor usually present which partakes of the character of neuralgia. This conclusion is founded partly upon the fact that the pain is not in proportion to the intensity of the uterine contractions even during the same labour, and partly that when the pain is disproportionately severe, there usually accompanies it other more or less distressing symptoms, such as nausea and vomiting, or the peculiar sinking feeling at the pit of the stomach; and besides, we find that pain is excessive more commonly in weakly women whom we should expect to suffer from neuralgia, rather than in those of a phlegmatic temperament. Of course allowance has to be made for the circumstance that one woman will bear with fortitude the pain which will demoralise another, also for the mechanical difficulties attending the dilatation of the maternal soft parts, and for the relative sizes of the child and mother. If this division be made, it is not more difficult to understand that the induced current will remove the neuralgia attending labour than that it will frequently do the same in other cases, while in no instance in which, when present, was the sinking feeling entirely removed, and I have not as yet met with a single instance of vomiting after the current was applied, although in several it was previously incessant.

As regards the influence of the current upon the pain produced by the second factor—namely, the uterine contraction—it may be stated, in short, that it is slightly diminished. One of the best methods of testing this question is by observing that when the contractions are intensified and prolonged under the influence of faradaism, the woman does not complain of their being more painful; and in one instance I was even begged to discontinue the current because "the pains were no good," although the pressure upon the child, as perceived by vaginal examination, was much more considerable than when the current was omitted.

Very nearly allied to the subject of pain is the constitutional effect of galvanism upon the woman. In Cases 2 and 3 the current was not used until the patient was prostrated, and her pulse rapid. In the former case not only did the fatigue disappear, and the pulse become slower, but the pains were absolutely intensified; while in the latter the prostration was removed, but no uterine contractions could be produced. These are the only two instances I have met with, because the patients in the other confinements allowed the coil to be applied before prostration became manifest.

Faradaism has a very striking effect upon the pulse rate during parturition, having a tendency to equalise it. If the rate be normal, the pulse is slightly quickened both during its use and also during the intermissions. But should the rate be much too rapid, it is lowered, and usually approaches the same number per minute as that to which in the former instance it rises. Taking an average, the number of the pulse beats per minute under the influence of the current is about 90; and this does not alter, as a rule, during or between the pains. It may be mentioned here that the after-pains do not seem to be in any way affected when the current has been used in labour, nor has anything gone wrong in any one case subsequently.

From what has already been stated, it is comparatively easy to say beforehand what patients are the most likely ones to be affected favourably by the induced current—viz., (1) those of a nervous temperament, who are easily excited, and who usually feel pain acutely; (2) those who have sympathetic disturbances, such as vomiting and hiccough; (3) those who require stimulation.

In my opinion, the best way of applying the current is to place the electrodes (each being about three inches in diameter) upon the abdomen over the motor points, these being retained in their proper places by the binder. It is very easy to make flat electrodes of spongio-piline by running through the waterproof covering several wires in different directions. Large electrodes are preferable to small ones, because the same current spread over a large surface is not felt so acutely as when it is concentrated into a small space. For the relief of pain a very mild current is only required, but for the production of uterine contractions a variable strength is necessary.

P.S.—Since writing the above I have used the induced current in forty-one cases. In all there was a diminution of pain, which was well marked in most. With one exception the uterine contractions were increased. In the exceptional case ergot likewise failed, and forceps were necessary on account of uterine inertia. Two women had sickness; one of whom suffered from bronchitis, and retching was induced by her cough. In the rest vomiting and nausea, when present, were almost instantly relieved. In every case the mother and child did well. The after-pains were in no way altered. In one case the current was applied for the relief of false pains ten days previous to her confinement, but was ineffectual.

Ladbroke-grove-road, W.

TWO CASES OF ANGIOMA.

By EDWARD LAWRIE, M.B. EDIN.,
PROFESSOR OF SURGERY, LAHORE.

IN April, 18—, a well-built, powerful Hindoo presented himself at the Calcutta Medical College Dispensary with a small fibrous tumour over the superior border of the right scapula. It was not attached to the bone, but was not freely movable. On this account I hesitated to operate on it, as the patient wished, in the dispensary; but as there was a crucial cicatrix over the swelling, left by a previous attempt on the part of a barber to excise it, I thought this might be the cause of its want of mobility, and proceeded to perform the operation.

Nothing unusual occurred at first, but with the final sweep of the knife to sever the last connexions of the tumour the most violent hæmorrhage took place I have ever seen. We were quite powerless to stop it till, in a few seconds, the patient fainted. I then managed to apply sufficient pressure to prevent its recurrence until I had held a consultation with my friend Dr. Bovill, who agreed to ligature of the subclavian inside the thyroid axis. When this had been done, with an antiseptic catgut ligature, the pressure was removed. Bleeding recurred, but was at once stopped by crucial transfixion and ligature of the vessels *en masse*. This was an extremely difficult procedure, because of the close and deep relation of the vessels to the mobile scapula. The same cause precluded the application of ligatures in any other way, as well as permanent pressure.

The patient rallied badly after the operation, and died on the third day.

On examination of the tumour and the wound, it was found that an angiomatous mass connected, as it were, the tumour with the soft parts about the upper border of the scapula. The growth itself was solid and fibrous, except at its base, which was occupied by a mass of tortuous dilated bloodvessels. No further post-mortem examination was allowed, and we were unable to satisfy ourselves as to the exact anastomosis which kept up the bleeding after the first part of the subclavian was tied.

This case, though disastrous, was sufficiently interesting, the more so as, within a short period, I had an opportunity of seeing a similar one, in the practice of the late Professor of Surgery in Calcutta, Dr. Gayer. In this instance the tumour occupied the lower and inner part of the thigh, and there was nothing whatever to indicate its angiomatous nature except, as in the first case, a deficiency of mobility. Dr. Gayer attempted its removal. From the commencement of the operation there was free bleeding, notwithstanding the use of Esmarch's appliances; but while the incisions at the base of the tumour were in progress it became so uncontrollable that Dr. Gayer promptly amputated the thigh, as the only possible means of arresting it. The limb was examined, and a large network of immense tortuous vessels was found occupying the base of the tumour, which was otherwise solid.

The extraordinary difficulty of controlling the circulation, which necessitated amputation, was explained by the state of the femoral artery. This vessel was dilated, atheromatous, and extensively ossified, so that not only was there no pulsation in the tumour in the first place, but the pressure of the elastic cord produced no effect on the calibre of the artery and the flow of blood through it during the operation.

UNIVERSITY COLLEGE HOSPITAL.
[THROAT DEPARTMENT.]
PARALYSIS OF THE CRICO-ARYTENOIDEI POSTICI OR DILATORS OF THE GLOTTIS.
(Under the care of Dr. POORE.)

G. S——, aged thirty-three, a carpenter, complained that for the last twelve months he had had a feeling "as if he breathed through muslin," and further stated that when he ran or exerted himself the breathing became stertorous. The voice was unaffected. On laryngoscopic examination the laryngeal mucous membrane had a normal appearance. During phonation the cords approximated thoroughly; during inspiration there was no abduction of the cords; the glottis remained a mere chink, and no effort of forced inspiration served to increase the distance between them. During expiration the distance between the cords was much greater than during inspiration. The arytenoid cartilages presented the appearance of being tilted backwards. He stated that sixteen years ago he had "a lump as big as his fist" on the front of his throat, and that one of his sisters had the same thing. This was probably an enlargement of the thyroid body. There was no lump or enlargement of any kind when seen; could swallow without difficulty. When pressure was made upon the posterior margin of the alæ of the thyroid cartilage there appeared to be some undue tenderness. There was no evidence of any intra-thoracic tumour; no paralysis of the tongue or palate; no want of laryngeal sensibility. There was a doubtful history of syphilis ten years ago. Patient said he had got thin lately, and looked depressed; suffers from pain under the eyes, and says that for the past three months he has occasionally, when at work, "felt shaky all over, especially in the head and eyes." There is no lead line; no tremor of the limbs; no symptoms of ataxy; no muscular wasting.

Remarks.—This patient was evidently suffering from that rare condition, paralysis of the crico-arytenoidei postici or abductors of the cords. All other muscles of the larynx, the adductors, and tensors, seemed to act perfectly. The cause of the peculiar appearance of the arytenoid cartilages was not evident. The cause of the want of power in the abductors was doubtful. The condition of the patient was more suggestive of hysteria than of any organic disease affecting the origin of the pneumogastric nerves. There was no evidence of any injury to the muscles themselves, or of any injury to the recurrent laryngeal nerves in their course. The patient was given iron and iodide of potassium, and was lost sight of when the hospital was closed for alterations during the past autumn.

PARESIS OF THE ADDUCTORS OF THE CORDS.

This condition, which is the one which gives rise to the so-called hysterical aphonia, is perhaps the most common of all the paralytic affections of the larynx. The paralysis is seldom complete, and therefore the term paresis seems preferable. Two cases occurred in girls aged respectively sixteen and eighteen. They were both completely aphonic, and quite unable to speak above a whisper. They were both anæmic, both suffered from globus hystericus, both were much troubled by vomiting after meals; and in both a furred tongue, with enlarged papillæ at the tip and edges, gave evidence of a condition of gastric catarrh. A laryngoscopic examination showed that the larynx was healthy, but that during attempts at phonation there was scarcely any approximation of the vocal cords, and that of a tremulous, hesitating character. The application of faradaism directly to the larynx was tried in both cases. It produced a momentary monosyllabic cry of discomfort, but no permanent benefit, and its use was not persevered with. The treatment was at first directed towards the relief of the gastric condition by the administration of mercurial purgatives, and this was followed by the treatment of the anæmia. A mixture containing perchloride of iron was ordered, combined with sufficient exercise and a nutritious diet. In both cases the aphonia had completely disappeared at the end of a few weeks.

The third case was that of a boy, aged twelve, who was completely aphonic, and had been previously treated for laryngitis. An examination of the larynx showed an extreme degree of paresis of the adductors of the cords, combined with a very marked anæmia of the larynx. The patient was an anæmic, delicate-looking lad, but the pallid condition of the laryngeal mucous membrane was far greater than that of any other part. It was indeed a real case of what has been described as laryngeal anæmia. He was treated by the administration of cod-liver oil and steel wine, and after a few weeks his voice became normally strong.

Remarks.—These patients are always *aphonic* rather than *hoarse*. Hoarseness is characteristic of thickening or roughening of the glottic aperture, which in these cases is never present, and accordingly we find that true hoarseness is very seldom observed. This form of vocal palsy, although often occurring in hysterical women, seems to be due in most cases to anæmia, and is probably caused by an actual want of muscular power in the adductor muscles. When the anæmia disappears, the voice returns, and it is very seldom necessary to have recourse to local treatment of any kind. The throat should not be coddled, but should be rather stimulated in moderation by the use of cold water. Fresh air is always necessary for these patients, and they should be made to take daily exercise out of doors.

OZÆNA.

In several cases of chronic inflammation of the nasal and pharyngeal cavities giving rise to offensive discharge, Dr. Poore has found decided benefit result from the use of a stimulant and antiseptic snuff having the following formula: biborate of soda, nitrate of bismuth, of each one drachm;

disulphate of quinine, ten grains; iodoform, five grains. This snuff has the effect of stopping the fetor and greatly diminishing the amount of discharge from the nostrils. It is liable, as are all snuffs when used for similar conditions, to cake in the nostrils, and it is therefore necessary to thoroughly wash out the nostrils once a day. This may be done by means of a nasal douche, or the patient may easily be taught to snuff a lotion up the nose and allow it to run out of the mouth. A teaspoonful of glycerine of borax dissolved in a wineglass of tepid water forms an excellent wash for the nose, and with a little instruction patients learn how to wash out their nasal and pharyngeal cavities without the aid either of syringe or douche apparatus. In cases where the ozæna is of a simple kind, not due to caries or necrosis of bone, but rather to a sluggish inflammatory action occurring in a scrofulous subject, considerable benefit is often derived from the administration of the sulphide of calcium in doses of half a grain (in pill), taken three times a day. It is often necessary to cleanse the nasal and pharyngeal cavities with a brush inserted through the anterior nares, and also behind the soft palate, so as to reach the summit of the pharynx. The brush may be moistened with glycerine of tannin, and after the cavities have been cleansed a little dry iodoform may be passed into the cavities on the tip of the brush.

NEWCASTLE-UPON-TYNE INFIRMARY.

EPITHELIOMA OF THE UTERUS.

(Under the care of Dr. PHILIPSON.)

FOR the notes of the following case we are indebted to Mr. E. L. Prowde, M.A.

C. B——, aged thirty-one, admitted May 11th, 1880. She admitted to having lived a dissolute life, and to having suffered from syphilis. Four months previous to her admission she suffered from pains in her loins, shooting round her back and down her thighs. Her menstruation was disordered. This was followed by a discharge, "like dirty-coloured water," of a very foul odour. There were also nausea, loss of appetite, and waste of flesh. On vaginal examination a growth was found of about the size of an apple attached to the cervix, fungoid and soft, and easily broken down with the finger. On microscopical examination of the detritus cancer cells were clearly recognised. On June 5th Dr. J. D. Dixon, the senior house-surgeon, with the écraseur removed the mass. The actual cautery was then applied, and ice was subsequently placed in the vagina. On July 4th, upon examination, it was found that the growth had returned. At this time Chian turpentine was administered internally. On July 24th it was noted that the discharge was not so copious nor so sanguineous, and also that it was not of such a foul odour. At the beginning of August, in consequence of the supply of Chian turpentine having been exhausted, the tincture of the perchloride of iron was substituted, but apparently not with the same beneficial influence as the Chian turpentine. The hæmorrhagic discharge again increased, and the pain also became greater. The pain was somewhat relieved by the hypodermic injection of morphia, and also with the morphia and belladonna suppository. Gradually her strength failed, and she died on Sept. 26th.

At the autopsy, the cavity of the peritoneum was found to contain a small quantity of sero-purulent fluid. The liver was firmly adherent to the abdominal walls by old bands. The pelvis was almost entirely filled with a hard white mass, resembling scirrhus, ascending to the pre-vertebral tissue, embracing the vessels and infiltrating the tissues. The same mass extended into the pelvis, matting together the pelvic organs. Attached to and surrounding the cervix uteri was a mass resembling brain tissue, as large as an orange. The body of the uterus was small, but normal. The left ovary was gristly and larger than natural. The liver presented the appearance of lardaceous degeneration. The kidneys were both large and pale, the capsules being adherent, and on section were found to be infiltrated with small nodules, almost like purulent punctures, collected apparently into groups, rather than being dispersed. The interior of the bladder presented raspberry granulations.

Remarks by Dr. PHILIPSON.—The chief interest of this case was the limitation of the disease to the cervix uteri, the fundus of the organ being normal. The cancerous growth had extended by infiltration to the surrounding textures, there being no secondary formations. The Chian turpentine had appeared to have been of service, the hæmorrhagic discharge having lessened during the time of its administration.

LINCOLN COUNTY HOSPITAL.

IDIOPATHIC ANÆMIA TREATED WITH ARSENIC AND DIALYSED IRON.

(Under the care of Dr. MITCHINSON.)

FOR the following notes we are indebted to Mr. W. J. Cant, house-surgeon.

K. J——, aged twenty-four, was admitted on August 16th, 1880, suffering from extreme pallor, having a peculiar yellow tinge, the mucous membranes looking perfectly white and bloodless. She complained of extreme weakness and slight headache, but otherwise no pain anywhere. There was diarrhœa, with occasional vomiting; but these symptoms did not appear until the disease was far advanced. On examining the organs no organic disease could be detected. The urine was free from albumen and bile, and there was no increase in quantity, nor was there any deposit. Specific gravity 1008. The patient took her food fairly well, and there was no pain after it. She was somewhat emaciated, and there was slight œdema of the legs. On auscultation loud anæmic murmurs were heard in the heart and over the cardiac region. No enlarged glands or spleen could be found. The catamenia were regular. The illness dated back for about twelve months, when without any cause the patient gradually lost her colour and became weak.

The blood, drawn with some difficulty, was on examination found to be watery and light in colour. Under the microscope the red corpuscles were seen to be much diminished in number, pale in colour, did not form rouleaux, but collected in heaps; many were irregular, some crenated, and others tailed with variations in size and undergoing movements.

Tested with the hæmoglobinometer the hæmoglobin was found to be only 10 per cent. of the normal. The temperature was raised and the pulse was quick and feeble.

Soon after admission thirty drops of a solution of dialysed iron was ordered to be given three times a day, with a diet of milk, beef-tea, and egg. Under this treatment the patient did not improve and seemed to be getting worse. Indeed, about three weeks afterwards a message was sent in the night that the patient was dying, and when she was visited scarcely any pulsations could be detected at the wrist, and the patient looked as though she could not last till the morning. Two ounces of brandy were given in water, after which her condition slightly improved.

On Sept. 5th three drops of arsenical solution were added to the medicine, and after a few days improvement was seen to have commenced, and the medicine was ordered to be given four times a day. In a few weeks the vomiting ceased, the colour began to appear in the lips and gums and the patient looked much improved. There was no diarrhœa and headache was not complained of. The pulse was fuller and less quick, the hæmoglobin was raised to 30 per cent., and the patient was allowed to sit up in bed.

On Oct. 4th (seven weeks after commencing arsenic) the hæmoglobin was 40 per cent. of the normal, the colour had returned to the cheeks, lips, and gums, and the patient said she felt quite well, and was allowed to leave her bed; and although at first there was marked weakness, she soon walked without difficulty, and in three weeks after the last date recorded she was sufficiently well to leave the hospital and perform her ordinary household duties.

Before leaving the hospital the blood was examined, and found to be of a bright and natural colour, the corpuscles were greatly increased in number, and the hæmoglobin was 75 per cent. of the normal. As regards the family history, the father had some enlarged glands in the neck, which were removed by Mr. Sympson, and there is one sister who is anæmic.

Aug. 16th: Morning temperature 102·0°; pulse 120. Evening temperature 104·4°; pulse 140.—17th: Morning temperature 102·0°; pulse 118. Evening temperature 102·4°; pulse 136.—22nd: Morning temperature 100·0°; pulse 114. Evening temperature 98·8°; pulse 110.—27th: Morning temperature 100·0°; pulse 118. Evening temperature 102·4°; pulse 130.—29th: Morning temperature 105·0°; pulse 140. Evening temperature 105·2°; pulse 144.—30th: Morning temperature 100·0°; pulse 118. Evening temperature 100·2°; pulse 120.—31st: Morning temperature 100·0°. Evening temperature 104·8°; pulse 140.—Sept. 2nd: Morning temperature 100·0°; pulse 120. Evening temperature 103·8°; pulse 138.—4th: Morning temperature 100·0°; pulse 120. Evening temperature, 101·4°; pulse 124.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Long-standing Stone in the Bladder, without Kidney Disease. —The Action and Use of Certain Remedies in Phthisis and Bronchitis.

AT the meeting on Dec. 20th, 1880, F. J. Gant, Esq., President, in the chair,—

Mr. PEARCE GOULD read notes of a case of Long-standing Stone in the Bladder, without Kidney Disease. S. S——, aged seventy-three, was admitted into Westminster Hospital on Aug. 3rd with symptoms of stone in the bladder severely marked. He had to pass urine every ten or fifteen minutes day and night, and had not had a good night's sleep for many years. He was very worn by the constant pain and efforts at micturition. The sound struck a large stone, which was so grasped by the bladder that it was impossible to move the short beak of the sound or open the blades of a lithotrite. Lateral lithotomy was performed next day, Mr. Morrant Baker holding the staff, and five stones removed. The patient at once experienced very great relief, slept soundly and well, was quite free from pain, and for several days went on well; but on Aug. 16th, without any complication arising, he sank and died. At the autopsy the bladder was found contracted to the size of an orange, with greatly hypertrophied walls, the mucous lining showing signs of old chronic inflammation. The ureters were not dilated, and the kidneys were healthy. The stones were about equal in size, facetted, weighing in all two drachms and a half, and were composed of a nucleus of uric acid, with a thick outer zone of phosphates. The points commented on by Mr. Gould were as follows:—1. The impossibility of performing any crushing operation in a bladder so contracted around a stone or stones. In such cases lithotomy must always be the only practicable operation. 2. The justification of lithotomy in a man so worn out. It lay in the entire relief of pain and comfort granted for the remainder of life, even if that be but short, as the man recovered from the shock of the operation, and lived eleven days, dying without complication or intercurrent disease; he may fairly be said to have died *after*, but not *from* the operation. 3. The number of the stones. Five large calculi were removed. 4. The immunity of the kidneys from disease in spite of the hypertrophy of the contracted bladder and long-continued cystitis and presence of a foreign body in the bladder. It was shown that this was probably to be explained by the mouths of the ureters not being obstructed by a band of thickened muscular tissue, as is commonly the case. A probe passed along the ureter slipped at once into the bladder under a fold of mucous membrane. The theories to account for the production of so-called "surgical kidney" were mentioned, and the bearing of the facts of this case upon them pointed out.—The PRESIDENT remarked upon the absence of renal disease rendering the case somewhat unique. Death was, no doubt, caused by exhaustion, and was not due to shock, which, in a patient of so advanced an age, would probably have followed in lithotrity.—Dr. EWART inquired as to the exact cause of death, and as to the condition of other organs, remarking that the immunity from renal disease might possibly be due to the smooth surface of the stones giving rise to but little mechanical irritation.—Mr. ROYES BELL related a somewhat similar case, in which he had performed lithotomy in preference to lithotrity.—Mr. GOULD, in reply, said that the severe sufferings of the patient determined him to operate, and the relief afforded justified the step. The case was quite unsuitable for lithotrity. There were no very definite signs of failure of any one organ, slight emphysema and atheroma of arteries being the only obvious lesions.

A paper communicated by Dr. LAUDER BRUNTON "On the Actions and Use of Certain Remedies employed in Bronchitis and Phthisis," was then read. (See p. 4.)

Dr. GILBART SMITH remarked upon the great value of the paper, and of its practical suggestions. He had often found simple remedies very useful in the arrest of cough—especially the short, hacking cough of phthisical patients. For some years he had been in the habit of prescribing a linctus of glycerine and milk (equal parts) with much success; it was soothing, demulcent, and harmless. He hesitated to give morphia in out-patient practice, knowing the carelessness of the patients as to the quantity taken; and had seen in one case almost fatal results follow from the too frequent repetition of a linctus.—Dr. JOHN BRUNTON could endorse all that the author had said, and gave an instance of the relief of violent cough by the topical application of morphia.

OBSTETRICAL SOCIETY OF LONDON.

Pygopagi Twins.—Eczema of the Nipple in Pregnancy.—Follicular Hypertrophy of the Cervix.—Induction of Abortion.

AT the meeting of this Society on Dec. 1st, 1880, Dr. W. S. PLAYFAIR, the President, exhibited the Conjoint Twins, Rosalie and Josepha Blazet, born in Bohemia in January, 1878. They belonged to the second of the four classes into which he had divided cases of double monstrosity—namely, "Two nearly separate bodies, united back to back by the sacrum and lower part of the spinal column." There is a broad and firm bony junction at the lower part of the lumbar region, the pelvis being obviously completely fused. There are two labia majora, a common urethral and anal aperture, and a double vaginal orifice, the septum separating the two canals being apparent. Sensation is quite distinct, except where the pelves are joined. Delivery was very easy, the mother not having been more than a quarter of an hour in labour. The head and shoulders of one twin were born first. The midwife now used strong traction, and thus delivered the feet of both children, the head and shoulders of the second twin passing last. This was the usual mechanism of delivery in such cases. Delivery is probably easier in this class of monstrosity; and hence, although this class is comparatively rare, a large proportion of the living monsters have been of this type—as, for example, the Hungarian twins, Judith and Helen; and the so-called two-headed nightingale, Millie Christine, exhibited some years ago in this country, and still living.

Dr. THOMAS CHAMBERS exhibited a drawing from a case of Eczema of the Nipple in both Breasts in a woman aged twenty-one, married six months, and five months advanced in her first pregnancy. The disease commenced when she was two months pregnant. After confinement it began to disappear, and no trace remained after six weeks. In two cases of long standing, apart from pregnancy, under his care, the eczema had been cured by treatment directed to the uterus, uterine symptoms having also existed.

Dr. HERMAN showed a specimen of Pedunculated Growth from the Cervix Uteri, removed by the écraseur at the fifth month of pregnancy; no ill result followed the operation, and the patient went to full term. When she came for treatment, she had been suffering from hæmorrhage for three or four months, and for about a week the tumour had been outside the vulva. The tumour measured $1\frac{2}{8}$ by $1\frac{3}{8}$ by $\frac{2}{8}$ in. It consisted of the normal tissues of the cervix, and contained glandular cavities from the size of a marble downwards, lined with cylindrical ciliated epithelium.

Dr. PRIESTLEY read a paper on the Induction of Abortion as a Therapeutic Measure. The author considered that the indications for the induction of abortion, as distinct from the induction of premature labour, had never been laid down with sufficient precision in this country. It was usual to say that each case must be judged on its merits, and this lack of rules might unfortunately lead to serious abuse. Examples had repeatedly come within his knowledge where abortion had been provoked for reasons which seemed to him quite inadequate. Though the medical man was, no doubt, acting in entire good faith in these cases, it would have been very difficult to sustain his action in a court of law. For instance, in one case abortion was induced at the fourth or fifth month on account of a bad rupture of the perineum at the last confinement. In a succeeding pregnancy a sound was introduced, with a similar object, at the end of a month. This, however, had no effect, and she went to full term, and had an easy and natural labour. In a second instance an attempt was made to induce abortion at the second month, because the patient had aborted not long before, and it was feared that pregnancy had recurred too speedily, while a much desired journey would have to be postponed if miscarriage recurred at the same period as before. Fortunately, the attempt failed, and the patient went to her full term. It was often necessary to remind wives and mothers that even spontaneous abortion is often more damaging to health than natural parturition, more frequently lays the foundation of disease, and, if repeated, abridges the period of youth and comeliness. These risks were necessarily greater if abortion was induced. The reasons which may be adduced as justifying the induction of abortion are the following:—(1) Pelvic deformity so great as to preclude the birth of a viable child. (2) Narrowing of genital canal by tumours, cicatrices, or cancer, so as to prevent the passage of a viable child. Great care was here necessary not to overestimate the amount of obstruction. If a series of cases of Cæsarean section, with fair success, should occur, the reasons for inducing abortion in such instances would be undermined. In cases of cancer there was fair ground for Cæsarean section, since the woman had but a short time to live in any case. (3) In obstinate vomiting of pregnancy, when all other expedients are fruitless, and a fatal result is anticipated, if relief cannot be afforded. (4) In eclampsia abortion should only be induced as a last resort, to save life. (5) In irreducible retroversion or retroflexion of the gravid uterus, but only when life is seriously threatened, not merely because the displacement is irreducible. (6) In severe hæmorrhage. (7) In certain other diseases where the complication of pregnancy is undoubtedly endangering life. The responsibility of inducing abortion should never be undertaken without a consultation of two or more medical men, and M. Tarnier had even suggested that a legal declaration should be made to the public prosecutor in every case. He would lay it down that the induction of abortion is only legitimate *when the life of the mother is so imperilled by the continuance of pregnancy that emytying the uterus presents itself as the only alternative to save the mother.* In insanity, chorea, and the like, the proper treatment was probably to treat the morbid condition, and leave the pregnancy to take care of itself.—The PRESIDENT said that it was somewhat curious that this important subject had not previously been brought under the notice of the Society. In one respect we could congratulate ourselves—namely, that so far as his experience went, the induction of criminal abortion was by no means so prevalent as in other countries.—Drs. Barnes, Hickinbotham, Murray, Graily Hewitt, Roper, Edis, Cleveland, and Hayes took part in the discussion, and Dr. Priestley briefly replied.

CAMBRIDGE MEDICAL SOCIETY.

Thrombosis of Pulmonary Artery.—Ruptured Tendon of Biceps Humeri.—The Colourless Corpuscles in Leucœmia.—Malformations in a Fœtus.

AT the meeting of this Society on Dec. 3rd, 1880, Professor Humphry, M.D., F.R.S., vice-president, in the chair—

Dr. ANNINGSON showed the Lungs and Heart from a case of sudden death with extensive thrombosis of the pulmonary arteries and an ante-mortem clot in the right ventricle. The patient, a woman aged about sixty, the subject of chronic bronchitis, was in the hospital for a slight injury to the ankle; she had raised herself in bed, and fell back in a faint, from which she could not be brought round. The branches of the pulmonary artery in both lungs were occupied by tightly-fitting clots of dark purple colour, mottled with greyish-white, granular on the surface, and with the proximal ends rounded or conical. A thin clot in the right ventricle had also the appearance of having formed ante mortem. Death had been from syncope, brought on by the abrupt and severe strain of raising herself in bed. During the syncope the blood had coagulated in the pulmonary arteries, and had made recovery from the faint impossible; an attempt at recovery would only serve to drive the clots farther into the branches of the artery. Referring to the part which the white corpuscles ordinarily play in coagulation, he thought it possible that the tendency to coagulation during life in the puerperal state, and in pneumonia, erysipelas, &c., was due to the excess of white corpuscles in those conditions.—Dr. HUMPHRY had had unusual opportunities of studying the process of thrombosis. When he first had occasion to observe it (in himself) he came to the conclusion that the clotting was dependent, not on the bloodvessels (veins of the lower extremity), but on something in the blood, although the medical attendant, according to the teaching of those days, called it pyæmia, and gave an unfavourable prognosis. Thrombosis is apt to occur at the end of a large number of maladies, the swelling of the limbs that one often sees on the post-mortem table being nearly always dependent on clotting in the veins. It occurs most commonly at the junction of the profunda and saphena veins with the femoral. The presence of valves at the meeting point of two or more veins helps to bring about the coagulation there; the stream of blood may be hardly strong enough to open the valve thoroughly, and it is not unusual to find a small piece of clot as if sheltering itself under the valve. Inflammation of the walls of the vein might follow the clotting, but was not the cause of it. The large proportion of colourless corpuscles in the blood did not appear to him to be a sufficient explanation of the tendency to thrombosis. The latter often occurred when there was no excess of leucocytes, and, for the cases where the leucocytes were in excess, the theory would rather require that the leucocytes should be more than ordinarily ready to part with that ferment to whose agency the coagulation was attributed. It was a remarkable circumstance, that although the veins may be choke-full of these clots, yet they will clear away entirely and leave the vessels as sound as before, and this may happen repeatedly in the same veins. The clot becomes reduced to a thin thread, and the last trace of the thrombosis is a slight staining of the wall of the vein. In the pulmonary artery, the clots are most commonly found at the point where it breaks up into its branches. He related the case of a lady who, having recovered from an easy confinement three weeks before, was sitting at the tea-table and fell dead without any warning. The pulmonary vessels were plugged with ante-mortem clots, which must have been formed for some little time, although there were no symptoms. He had before him a specimen which he had placed in the museum, the only specimen of the kind that he knew of, showing a dissection of thrombosis of the pulmonary artery which had been recovered from. The clots were reduced to firm cords blended with the walls of the vessels. The patient died of erysipelas, with fresh thrombosis of the popliteal and femoral veins, and with these traces of old thrombosis of the pulmonary artery. The woman whose case had been brought forward by Dr. Anningson had been under his (Dr. Humphry's) care in the hospital for about ten days with a slight injury to the ankle. He found her one morning breathing with difficulty, and he was told that she frequently had such attacks, called asthmatic; on the same day she sat up on the bed-pan, and fell back dead. The clots were mostly in the smaller branches of the pulmonary artery, as if there had been simultaneous clotting in the small vessels. As regards the veins of the extremities, he had observed the thrombosis in one attack to begin at the groin and extend down the thigh, and, on another occasion, to begin about the knee and extend upwards. Patients with that condition were usually advised to avoid movements, but he questioned whether the accident of the loosening of a large piece of the clot was at all more liable to occur when the patient went about as usual.

Dr. HUMPHRY showed a specimen from a female subject in the dissecting-room of Ruptured Long Tendon of the Biceps Humeri. The injury is one that can often be recognised during life (by the weakness of the limb, and the muscle drawing itself up into a lump), but he had not seen a dissected specimen of it before. By far the larger number of cases are due to rheumatism, the tendon having become fixed in the bicipital groove. In this case it had been ruptured where it was most liable to rupture—in the part which passes over the head of the humerus. The preparation shows the lower end drawn down and adherent to the belly of the muscle, coiled upon it in the form of the letter S; it looks as if it had been ruptured a long time. In the upper fragment no changes whatever have taken place; it lies within the joint, and its frayed-out end has the appearance of being newly broken.

Mr. SHANN exhibited a patient from the hospital, with well-marked Splenic Leucæmia, and gave an account of observations that he had made on the blood. There was an enormous increase in the number of white corpuscles, the ratio of white to red being about one to five or six. The total number of blood corpuscles was much below the normal standard. On admission there were 70 per cent. of the normal number, but a further reduction subsequently occurred. Among the white corpuscles were a large number of extraordinary size, and often filled with highly-refracting large granules. He had taken the opportunity of verifying in this case the statements recently made by Dr. Cavafy as to the loss of amœboid movements in the colourless corpuscles in leucæmia. He had made several observations, the most reliable of which (at a temperature of 98° to 100°) gave 10 per cent. of the colourless corpuscles as amœboid, while many more retained the power to a slight degree. He considered that the observed absence of amœboid movements would help to distinguish true leucæmia from the merely physiological leucocytosis.

Dr. ANNINGSON showed and gave an account of a case of Ectopia Viscerum, and other malformations in a fœtus. The abdominal wall was open in front, and the whole of the small intestine, the liver, and other organs, formed a bulging mass outside the cavity. The chief point of interest was the absence of the greater part of the large intestine; the ascending, the transverse, and the descending colon were as if omitted, and all that represented the large intestine was a piece of gut in the position of the cæcum, but open in front. This was really a uro-genital sinus, or cloaca, the two ureters opening upon its skin-like surface a little farther down.

Reviews and Notices of Books.

Clinical Lectures, and Cases with Commentaries. By HENRY THOMPSON, M.D., M.A. Cantab., F.R.C.P. Lond., Consulting Physician to the Middlesex Hospital. London: J. and A. Churchill. 1880.

IT is seldom—very seldom—that medical books are produced by the veterans of the profession for the first time embodying facts from their store of experience in pages to be transmitted to their successors. Less frequent still is it to meet with such contributions full of the zeal and freshness which might be expected at an earlier period of life, when experience has yet to come. Nor is this to be wondered at, for after many years spent in the service of the sick, it may well happen that the energy requisite for such a work should be lacking, whilst in view of the constant additions to pathological knowledge, an author might properly pause before venturing to stereotype his "views." These might, it is to be feared, meet with but a scanty recognition. The tide of seekers after some "new thing" flows past his standpoint, and he will be left alone, unheeded, his words of wisdom and fruits of long experience being but impatiently listened to, if he gain a hearing at all. Far otherwise, however, is it with the volume before us, which we venture to think will be widely read, and thoroughly appreciated, even in these days of keen thirst after novelty. It may be said to comprise the chief results of the author's experience during the last eight or nine years of his long term of office as a hospital physician. For this reason alone the book should be valued; but it has other merits. The chief of these are the originality, terseness, and vigour that mark the lectures; which, added to the polished and clear style in which they are composed, must have made them very attractive to the hearers, whilst they cannot fail to charm the reader. They are models of careful clinical analysis; point after point being discussed with precision and a rare freedom from dogmatism. Compared with the lectures of Trousseau or of Graves, they certainly appear brief, but they are, in their way, quite as effective and characteristic as the widely known works of these masters in clinical literature. In a word, they are finished *studies* of cases occurring in hospital practice.

This is high praise. To those who are unacquainted with Dr. Thompson or his work it may sound exaggerated, but it is not more than is deserved. Many of the lectures are reprinted from the journals or Transactions in which they first appeared, but some have never before been published. To enumerate all the subjects which come under discussion would not be possible within the limits of a brief notice like this. It may be imagined that they are of great variety. "Cerebral" rheumatism occupies a prominent place, and the prodromal relation borne by nerve-symptoms (of one kind or another) to the frequently-occurring hyperpyrexia in these cases is dwelt on and emphatically urged as of prime importance. Dr. Thompson does well to enforce this lesson strongly, for upon it depends sometimes a question of life or death. The occurrence of "nerve-symptoms" in the course of acute rheumatism should give the signal for a careful and minute record of the thermometric curve, lest a sudden and rapid rise in temperature place the patient in a condition of peril from which even the most energetic antipyretic measures cannot restore him. The cases recorded by Dr. Thompson fully justify his insistance upon this line of action.

Another subject, discussed in more than one lecture, is heart disease, and particularly pericarditis, great stress being laid by the author upon the tripartite cantering rhythm of the cardiac sounds, which invariably precedes or accompanies the friction sound; and an interpretation of this sign is given which differs from that of Johnson and Hyde Salter. Pneumothorax, intestinal obstruction, various forms of abdominal cancer, abscess of the brain in relation to ear disease and pyæmia, male hysteria, thrombosis of the vena cava, form the basis of other lectures and commentaries, the text of each in turn being a case, of which in the majority of instances the clinical observation has been supplemented by the post-mortem record. The author has done wisely in thus selecting completed cases for his dissertations, for clinical work is only half done when confined to the limits of the ward. There is room for this book and many like it. In this instance the interest and importance of the subjects are heightened by the scholarly manner in which they are treated by their esteemed author, who in his preface characteristically says, "Although I have ventured to lay this book before the profession at large, my main purpose is to leave it as a legacy to the Middlesex Hospital—*in memoriam.*" We trust that some day he may think fit to add further to our obligations, by the issue of more lectures of this stamp.

The Cæsarean Section, &c. By THOMAS RADFORD, M.D. Second Edition. London: J. and A. Churchill. 1880.

THE first edition of this work was published fifteen years ago, and three years subsequently a supplement. In the present edition considerable additions have been made, in which the statistics of the Cæsarean section and craniotomy, and other subjects, are discussed. Brief notes are also given of the modifications of the Cæsarean section proposed by Blundell and Porro, and of the operation—gastro-elytrotomy. Dr. Radford has long been known as an able advocate of the Cæsarean section as opposed to craniotomy; not that he would abolish the latter operation entirely, but he would restrict its field in a very great degree. He writes: "I have been asked by an eminent obstetricist if I dispute that craniotomy may not be resorted to 'to save the mother's life.' In answer to this question I beg most emphatically to say 'Yes.' When her life is jeopardised by some temporary existing cause, and other circumstances, I would conditionally make craniotomy no operation of election." Again: "Two cases, in one of which there is only a limited degree of contraction of the pelvic brim, and in the other an extreme degree of diminution in the aperture, are not analogous. In one—'the first'—craniotomy will only be required to be performed *once*, as, in the event of subsequent pregnancies occurring, *premature labour* may be induced and the *infant thereby saved;* whereas in the other case craniotomy would have to be performed time after time. In such cases my conscience tells me such horrible destruction of life cannot be defended on any ground whatever." Besides the moral argument in favour of the view he adopts, the author brings forward others of considerable weight, such as the loss of maternal and infant life in craniotomy, though statistics with regard to the former are very deficient. Again, he attempts to show, and with great reason, that the high mortality after Cæsarean section is not really the result of the operation, but is in great part due to other causes, some of which may be eliminated. The operation has been often done as a last desperate attempt to save life after craniotomy had been already performed in vain, or after the patient had been in labour for days; when, in fact, there was not the least reason for expecting a favourable issue. It is quite possible that with proper precautions the mortality of the Cæsarean section may be considerably reduced, and that in consequence the operation may be placed in a different position from that which it now occupies. The general opinion and practice of the profession at present are against the views advocated by Dr. Radford; but it is not impossible that with greater care and better methods of operating a more favourable opinion of Cæsarean section may become general.

A Clinical Note-book for Hospital and Private Practice. By F. Royston Fairbank, M.D. Fourth Edition. London: John Smith & Co.

We are strangely poor in convenient forms of clinical note-books. This is a good attempt to supply the lack. It is not quite perfect in form; it has no index, and the pages are not numbered. Besides, it lacks a few notes and tables, physiological and pathological, that such a book should have. But it is one of the best published, and we advise all our readers to begin the year with some such easy means of recording cases.

THE MEDICINE OF THE ANCIENT JEWS.

Our knowledge of medical theory and practice among the ancient Jews is far behind our information with regard to other nations, and it is very small when we consider the large amount of Hebrew literature which has come down to us. The code of Jewish laws contained in the early books of the Bible presents us only with an elaborate system of preventive medicine. On many points, however, on which these books are silent, we may gain some knowledge from the pages of the Talmud, and M. Israel Rabbinowicz has lately collected and republished all the passages relating to medicine which are to be found in the twenty-one books which make up that venerable work. These collected passages have furnished the subject of an interesting series of articles which have appeared in our Paris contemporary *L'Union Médicale.*

As might be expected, the ideas of the Jewish doctors of the law, the chief practitioners of medicine, were of the crudest character. They possessed, however, some vague knowledge of anatomy, and allusions are made to two dissections of bodies, in which the remarkable fact was ascertained that a woman has four bones more than a man—the former being found to have 252, the latter 248. However mysterious the conclusion may be, its definiteness affords proof that the dissection must have been at least thorough. In a curious story is narrated a discussion regarding the position of the lower extremity of the spinal cord. Many of their notions betray, however, very imperfect observation. For instance, they believed that the urethra presented throughout its length a fine septum which divides it into a spermatic and a urinary canal. They believed that by long retention of urine this septum might be rent, and a fistulous opening between the two canals result—a "spermatico-urinary fistula,"—which would render a man sterile. Hence they drew the useful lesson that there should be no avoidable delay in micturition.

The physiology of the Talmud is grotesque enough in some particulars. "The kidneys give advice, the heart understands, the tongue produces articulate sounds, the mouth completes them, the œsophagus receives and rejects food, the trachea produces the voice, the lungs absorb liquids, the liver is the seat of rage, and the gall-bladder throws bile upon it and calms it, while the spleen is the seat of laughter." Amongst other duties of the learned doctors was the superintendence of the slaughtering of animals. Arguing from their physiological knowledge that the trachea and œsophagus are the structures most essential to life, they ordered that all animals should be slaughtered by the division of these only. A certain Rabbi, having observed that this was not a very speedy mode of death, suggested the division of the bloodvessels of the neck, but his advice was overruled.

Pathological descriptions are so vague that it is difficult to identify the diseases indicated. In one case, for example, it is difficult to know whether blenorrhagia or spermatorrhœa is indicated. Venereal diseases appear to have been very frequent among the Jews, for a whole treatise is devoted to them; but the accounts are so loose that we cannot now say what diseases are indicated. Much discussion is devoted to the subject of the various "swellings," but the conditions are not further described. Etiology is not more definite than symptomatology, for the three causes to which these diseases are ascribed are witchcraft, fornication, and inanition. The familiar tendency in pathology to multiply diseases by making slight variations distinctive is one of great antiquity, and perhaps never attained a higher pitch than among the Jews, for they distinguished (but did not describe) no less than eighty-three different diseases of the gall-bladder.

The practical duties of the professors of physic were in part hygienic, and were curiously mixed. They had to select the parts of slaughtered animals which should be eaten. They had to detect and recognise the signs that an individual had passed puberty, the signs of virginity, of sterility, and of impurity. Surgery seems to have been almost unknown, but in their methods of treating wounds &c., a certain rude ingenuity was displayed. In the case of a urethral fistula, for instance, the first object was to ascertain whether the semen escaped by the orifice. If it did not, the escape of urine apparently was of little moment. But, of all disasters, impotence and sterility seem to have been thought the greatest. If the semen escaped the following operation was to be performed. The part was first to be rubbed with a grain of barley, then with fat, and, lastly, a large ant was to be applied to the opening. It would bite and attach itself there and then; the head of the ant was to be cut off and left in the wound, in the expectation that this would be effectually closed when the head decomposed. In a case of fracture of the skull, an ant not being large enough, the absent fragment of the cranium was replaced by a piece of dry pumpkin. The patient lived all the summer with his cucurbitaceous cranium, but could not support the cold of winter. M. Rabbinowicz believes that the Jews had some knowledge of the use of anæsthetics, since we read of an individual to whom was given a "remedy to cause sleep before the abdomen was opened."

The therapeutics of the Talmud consist almost wholly of hygienic rules, although one sage recommended bleeding every thirty days as a preventive of disease, and he also indicated certain days of the year and week on which venesection was most advantageous. The opinion ascribed to Rabbi Banaah may, perhaps, have been general. He said: "Wine is the best of remedies; it is only where there is no wine that drugs are necessary."

THE LANCET.

LONDON: SATURDAY, JANUARY 1, 1881.

IT is a little startling to find members of the medical profession classed as "Commercial" in the *Post-office Directories*. It requires some moral courage to face the official fact that the "art and mystery" of the physician is publicly considered a "Trade"; but the old dictum—or distich—which designated the "learned professions three; law, physic, and divinity," even though the order adopted by the versifier may be fairly reversed, might have been confidently trusted to preserve us from the social ignominy of being classed as commercial men. There is a "Legal" department in the Post-office Directory, and it would have been a great public convenience, as well as a simple act of justice to the profession, if there had also been a "Medical" department, giving the names and qualifications, and perhaps the principal hospital appointments, of medical men—an improvement which, looking to the omission of names from the "Commercial" and "Trade" sections, could scarcely have added half-a-dozen pages to the bulk of the already large volumes. We commend the suggestion to the commercial instinct of the promoters of the Post-office Directories, in view of their next issue.

Meanwhile it cannot be gainsaid that the medical, like every other profession, *has* a commercial aspect; and if this is to be, somewhat offensively, thrust upon our attention, and upon the notice of the public at the commencement of each new year, it will be only just, and may be prudent, that we should take this phase of our social relations into serious and practical consideration. The time has passed, perhaps for ever, when the professors of physic could claim to practise solely, or even chiefly, for the advantage of the community, and the humane gratification which the relief of suffering always affords. Setting aside the craft of the apothecary, which was from the first a trade, Medicine used to be a calling affected by none save gentlemen and scholars, who "went out," as the phrase was, from their university, "in Medicine" as in Divinity or Law. The doctors of physic who practised as physicians were then something more than graduates in technicology; they were men of general culture. A great change has come over the medical profession in this respect. The progress of technical knowledge has, or is *supposed* to have, led to the neglect of literature and science—in its wide scope—for the specialties that make up what is called a "medical education." Possibly this change has necessitated, certainly it has in some way brought about, the introduction of an order of men and minds into the medical profession which were not in old times attracted to it. A glance down the lists of the working, as distinguished from the more ornamental, bodies that people the world of science, will show that the names of medical men of the present generation are chiefly conspicuous by their absence. The reason is not far to seek. It is not that the physicians and surgeons of to-day are less scientific than those of an older date—we had almost written *age*, so great was the difference. On the contrary, their acquaintance with the technicalities of science is incomparably more precise and practical than that possessed by their predecessors, but they are too much engrossed with the busy—marketable—work of their profession to command the "leisure" which makes learning a pastime and the pursuit of knowledge a pleasure. It is not a pleasure to be hunted from covert to covert with the baying of a pack of examiners at one's heels. The modern system may tend to the development of a devouring greed for intellectual food; but it will be strange if the next generation, in the sequence of heredity, finds that the "culture" so accomplished has actually proved ennobling. In short, there is an ever-present danger of the sort of *education* this system fosters suddenly degenerating into a process of "cramming" instead of culture. The safeguard—though a sorry and ignoble protection at the best—against this evil may be the recognition of that "commercial" aspect of medical work which is now forced upon us. Already it is beginning to be whispered in the nooks and corners of the medical academia that the test of practical—that is, "commercial" or market—value must be applied to the details of the professional curriculum.

Again, in the active part the medical profession plays in the world, it is beginning—and not too soon—to perceive, and in some sort to assert, its commercial character and claims. If, indeed, we are men of commerce, it is nothing more than just that we should claim a fair recompense for the pains we expend in the service of the public. As yet, it is to be feared, this logical consequence of the commercial status attributed to us is not clearly recognised. We are to be classed and treated as commercial men, but we are not, forsooth, to consider our commercial interests. The practitioner of every other craft except the medical may make gain an object, but the medical man must ever adopt his scale of fees to the convenience of those who should be in need of his services! Why, in the name of common sense, should this be expected of *us?* The baker does not bestow any great wealth of benevolent consideration on the need of his customers, although he deals in "the staff of life," without which they would probably die of starvation. Why should the medical man be asked to accept a nominally inadequate requital for his services on the parallel ground that without the assistance he could render the sick may die of disease? The humanitarian aspect of medicine as a calling has been strained to suit the false sentiment of a maudlin age until it has become ridiculous. The money value of the work done gratuitously for society by medical men in connexion with hospitals, dispensaries, and in their private capacity is enormous. No other profession or trade contributes anything even comparable with the service freely given by the medical, looking solely to its money value! And this will continue to be the case so long as we forbear to read the lesson of prudence pointedly inculcated by the place assigned to us in the Post Office Medical Directories.

We are quite prepared to accept the onus of taking the lead in a strong recommendation that the medical profession should signalise the year on which we are entering by a more politic regard for its own interests. Those interests are not incompatible with the good of society, and it is high time the practitioners of medicine began to think of themselves and the families depending upon them. It is a morbid sentiment that makes us cling to the traditions of the past, now that those traditions have been ruthlessly uprooted. As regards hospital work, the popular delusion that physicians and surgeons are recouped for their labours by the opportunities of gaining experience, should be shown to be a myth. As a matter of fact, the great bulk of the profession has nothing whatever to do with hospitals, and never had, except while *in statu pupillari.* It is also apparent that the public do not set a very high estimate on the value of hospital appointments, seeing that some of the most successful and most widely known practitioners are not connected with public institutions. It has been the fashion for the most enterprising men in the several branches of medical work to seek and to hold hospital appointments; but this does not prove that these men are in any fair degree recompensed for their exertions, and as a matter of experience, we believe, it will be found that the services thus rendered are not even acknowledged. The sacrifice of time, strength, and, in too many instances, of health and life itself, is final. Meanwhile, the great bulk of gratuitous practice, whether in connexion with hospitals and dispensaries or in private, is chiefly noticeable for the pecuniary loss and injury it entails on the general body of the profession. We want a little plain speaking on this subject, and as a word peculiarly in season just now, let us say the profession would not be less truly "humane" or "public-spirited," if it thought a little more of its own interests and those of its most hard-worked and humbler members, and if the exercise of the gracious gift of charity were a little less demonstrative, and began at home.

◆

THE movements of plants have attracted attention from a very early period; and although at one time the absence of the power of locomotion was regarded as one of the characters by which plants could be distinguished from animals, the partial movements of such organs as the leaves and flowers were familiar to all, and probably constituted the basis of the ancient legend of the metamorphosis of animals into plants. In the great majority of instances the movements observed were referred, as in the case of climbing plants, to the act of growth directed in a singular and exceptional manner, or to variations in the hydrostatic conditions present, or merely to the action of heat or light, without any attempt being made to explain them further. There were some instances, however, in which it was seen that they were of a more complex and remarkable character, and that no such explanation was admissible. The movement of the leaves of the sensitive plant, of the singular leguminous plant Desmodium gyrans, of the Dionæa, and others, were too sudden and too obviously produced or affected by stimuli to allow them to be referred to growth, or changes of temperature, or of light; and it became requisite to admit the possession by plants of a certain degree of irritability analogous to that of animal tissues. Various observers (as SACHS, DE VRIES, VINES, and FRANK) have of late years turned their attention to this interesting subject, but none with greater ability and success than Mr. DARWIN. In 1875 he published an essay on the "Habits and Movements of Climbing Plants," in which work he demonstrated that the climbing power was the consequence of the exaggeration of a form of movement common to many plants. He observed that the tip of every climbing plant is constantly performing gyratory movements, to which he applied the term "circumnutation"; for if minute spiculæ of glass or a bristle be attached to the tip, and a tracing taken by allowing the spiculum to rest against a plate of smoked glass, indisputable evidence of the direction and rapidity of the movement can be obtained; the tracing forming, not indeed, as it should do, considering the plant is growing, a circular spiral, but irregular elliptical or oval figures. Now, these movements are partially due to the increased growth of the side which for a time becomes convex, and this is preceded by a state of increased turgescence of the cells on the convex side, and, as Mr. DARWIN believes, by a certain degree of increased extensibility of the cell wall. His more recent researches, which have just been published under the title of "The Power of Movement in Plants,"[1] have led him to the conclusion that circumnutation is not limited to tendrils and the tips of climbing plants alone, but is far more widely distributed through the vegetable kingdom—in fact, that it is a power possessed and actively exerted in every growing part of every plant, though often only on a small scale. Even the stems of seedlings, before they have broken through the ground, as well as their buried radicles, circumnutate as far as the pressure of the surrounding earth permits. In the volume to which we have just referred, Mr. DARWIN gives the tracings, magnified, of the movements performed by the radicle of a seed of Brassica oleracea, and others of the radicles of Githago, Oxalis, Citrus, and many familiar plants. In all instances these tracings form irregular zigzag but more or less elliptical figures, indicating a gyratory or circumnutatory movement of the tip of the radicle. Similar tracings obtained from the epicotyl or plumule of a growing seed gave the same indications of movement. It is remarkable that in all instances examined —and they were many—the plumule of a growing seed breaks through the ground, not by its tip, but in the form of an arch, and thus, as HABERLANDT has shown, the tender apex is saved from abrasion and pressure whilst breaking through the ground. Mr. DARWIN adds that increased force is gained, since the crown of the arch is pushed up with just twice the force that would otherwise be exerted. In the case of the common bean the epicotyl after the apex had freed itself from the seed coats, grew upwards with a force sufficient to lift a thin plate of zinc loaded with twelve ounces.

The irregularity of the ellipses formed by the growing radicles of plants naturally suggests that causes are in operation to modify what would otherwise be uniform and regular, and Mr. DARWIN'S observations have shown this to be the case. The radicles of plants may be said to be primarily affected by gravity which leads them in their growth to penetrate the earth; or, to express the fact shortly, they are geotropic. In the next place they circumnutate, the importance of which is that it enables them to take advantage of crevices and spaces, such as worm burrows, existing in the soil. But in addition, a special kind of sensibility, or rather of irritability, appears to exist in the tip, and yet another in that part of the radicle which is a little above the tip. The tip is sensitive to any steady and continuous pressure on contact, and conducts an impression, which leads the part above the tip to bend away from hard or irritating objects, and enables the tip, in conjunction with the circumnutatory movements, to pursue the lines of least resistance in the soil. The part above the tip, on the other hand, so reacts to direct pressure or irritation as to cause the apex of the radicle to bend, not away from, but, like a tendril, towards the object touched. The radicles of the bean and pea exhibit these peculiarities in a very marked manner. Then, again, the tip is very sensitive to moisture, and possesses a strong tendency to bend towards the source of the moisture; and, lastly, the roots of plants are excited by light, and bend in some instances to, but usually from it. Their course through the soil is thus governed by extraordinarily complex and diverse agencies. The sleep or nyctitropic movements of plants are full of interest. These movements are due partly to turgescence of cells, especially of those forming a pulvinus at the base of the leaf or leaflet, and partly to alternately increased growth on opposite sides, and they beautifully illustrate the theory of evolution; for whilst they are primarily only circumnutatory movements, by undergoing special modification they come to be of particular service to plants, effecting the protection of the upper surfaces of their leaves from radiation into the open sky, and also protecting them from cold by approximation. No exception was found to the rule that leaves which sleep continue to move through the whole twenty-four hours, though always more vigorously on going to sleep and on awaking. Light appears to act especially on the young and growing parts of plants. Mr. DARWIN finds that there are thirty-seven genera, in which the leaves or leaflets rise, often moving at the same time towards the apex or towards the base of the leaf, and thirty-two genera in which they sink in sleep. In his observations on leaves and stems, Mr. DARWIN finds that, on exposure to light, they almost uniformly bend towards it, or are heliotropic, and this he believes to be due to augmented turgescence taking place along one side. It does not seem clear, however, nor does Mr. DARWIN attempt any explanation, why this turgescence should occur on the side away from the light. Other leaves are apheliotropic. Increased turgescence is commonly followed by increased growth, so that a plant which has bent itself towards the light during the day would be fixed in this position were it not for apogeotropism acting during the night. During the day most leaves and cotyledons dispose themselves transversely to the direction of the light—a movement to which he applies "diaheliotropism," and which he again considers to be due to modified "circumnutation." Some seedling plants exhibit extraordinary sensitiveness to light; the cotyledons of Phalaris, for example, become curved towards a distant lamp which emitted so little light as to throw, at the distance at which the plants were, no shadow from a pencil upon a white card. Other seedlings kept in a dark place were laterally illuminated by a small wax taper for only two or three minutes, at intervals of about three-quarters of an hour, and were all found to bow towards the point whence the taper had been held. Most, if not all, of the movements of plants due to the action of light appear to be a modification of circumnutation. Another interesting fact in some seedling plants is that the uppermost part alone is sensitive to light, and transmits an influence to the lower part, causing it to bend. Hence, if the upper part be wholly protected from light, the lower part may be exposed to it for hours, and yet does not become in the least bent, although this would have occurred quickly if the upper part had been excited by light. The discovery of the general fact of the movement of the growing parts of all plants must have been a matter of special self-gratulation to Mr. DARWIN, for it removes one of the difficulties—and by no means a trivial one—in the way of the theory of evolution; for it might, as he observes, well be asked, How did all the diversified movements of plants, for the most different purposes, first arise? As the case stands now, movement has been ascertained to be always in progress, and its amplitude or direction, or both, simply undergo modification for the good of the plant in relation with internal or external stimuli.

◆

THE last three meetings of the Pathological Society have been almost exclusively occupied with a discussion on Rickets, and we may fairly presume that those who have been specially working at this subject have availed themselves of this opportunity of publishing their results and elaborating their views. The debate has been very fully reported in our columns, and we must therefore refer our readers to those reports for the expressed opinions of individuals, while here we draw attention to one or two of the points raised. But first of all we must warn those who read this debate that they will find but little of the nature of fact or recorded observation, while there is abundance of theory and opinion, more or less valuable. Nor is this because the disease is one of which the facts are already well and fully known, or difficult to arrive at. If there is one malady which thrusts itself before the gaze of hospital surgeons and physicians, almost *ad nauseam*, it is rickets, and possibly it is in this abundance of the material at hand that one reason of its apparent unattractiveness lies. It was only in the closing speech that a word was said as to the condition of the blood in rickets, and not one speaker made any reference to the chemistry of rickety urine, if we exclude a remark—a query — of Dr. HILTON FAGGE'S, which was at once replied to by Sir WILLIAM JENNER. Nor was the composition of rickety bones more satisfactorily dealt with; the only observation on this point that could lay any possible claim to the name of fact was to the effect that the proportions of animal and earthy matter were the same in rickety and healthy bones, as shown by rough analyses of two specimens of each. So little interest was evinced in the matter that no one of the subsequent speakers ever alluded to this result, so diametrically opposed to commonly received notions, and the evidence of our unaided senses. The histology of rickets was also but slightly touched upon, and certainly no light was thrown upon its difficulties. Indeed, with few exceptions, the speakers were at greater pains to ask than answer questions, and appeared to labour under the pleasing delusion that there was an omniscient spirit—the Society—to whom they might propound their theories and state their problems, and await patiently, but confidently, for final criticism and answer.

There is certainly agreement among all English authorities that in no just sense can rickets be called a local disease; like other general maladies, its local effects may often be obscure to a careless and superficial observer, the general systemic derangement, while again in other cases this is very marked, without or previous to striking local deformities. In all this there is nothing novel. To many it has appeared strange that the suggestion should ever be made that the parent of rickets is syphilis, and the present discussion contains more than one weighty opinion and observation to refute this suggestion. Sir WILLIAM JENNER evidently thought it hardly worthy of serious discussion, as the facts by which it can be set aside are known to all practitioners. But far otherwise is it with the other question, as to whether syphilis plays any part in the production of rickets. Both diseases are so common, and common among the same class, and in the same conditions of poverty, dirt, and neglect, that to prove a negative must be difficult. Yet we may fairly say that no evidence was brought forward to show that there exists any close relationship between these two affections; while, on the other hand, there are no facts known to lead us to suppose that there is any antagonism between them, and that one protects from the other. Indeed, he would be a bold man who would refuse to think that the debility induced by congenital syphilis may not render the child particularly liable to become rickety if under suitable conditions. A good deal of attention was directed to the subject of cranio-tabes, introduced into the discussion by Drs. BARLOW and LEES. We have already pointed out that, valuable as are their researches and results, they cannot be held to be decisive on the essentially syphilitic nature of this change. The delay in the ossification of the bones, evidenced by the widely open fontanelles, is so characteristic of rickets that, even if the softened condition of the posterior inferior angle of the parietal bones be demonstrated to be due to the influence of inherited syphilis, it will still remain a question whether that influence be not solely exerted in localising, perhaps also specialising, a really rickety affection. The frequent occurrence of Wormian bones just at this spot in the lambdoidal suture suggests the inquiry whether they are in any way connected with the tabetic change.

A very valuable contribution to the etiology of rickets was made by Dr. BAXTER, who has carefully studied the life history of about 120 consecutive cases of rickets. He is of opinion that the disease is the result not only of general bad hygiene, but particularly of a too early administration of starch to children unable to digest and assimilate it. This is a view that has been long held by many others, but Dr. BAXTER has done good service in making an effort to define exactly the part starch feeding plays in causing the disease. His figures will be found in our report. They show that while the place in the family, previous ill-health, heredity, and other circumstances, appeared to have but small, if any, influence, starch feeding was practised in an overwhelming majority of his cases. How the starch acts is a far different question to determine, and, indeed, before we can accept the starch theory at all, there are some apparent difficulties that require to be removed. One of these is the rarity of rickets in country districts in England, where it appears to be limited almost, if not quite, exclusively to towns; another is the rarity of rickets in America, and its absence in certain parts of India. Very probably information on these points may show that they support rather than confute the starch theory, which has, beyond direct evidence, much *à priori* reason in its favour. The absence of starch in milk, which so completely nourishes the infants of all mammalia, not only shows that it is an unnecessary article of diet at that age, but suggests, if no more, that it would be actually harmful. But even if we grant that starch feeding be the most common cause of rickets, need we refer all cases to it? Is it such a special disease that it has for its cause only one improper food element? There are strong reasons for doubting this. The first is that starch feeding is the greatest, most constant, error in the diet of infants; another is the frequency with which acute diseases—sometimes also chronic—are followed by the first appearance of rickets; and a third is the occurrence of rickets at and about puberty. No heed was paid to either of these points at the Pathological Society, but there is evidence that can hardly be controverted or set aside that rickets may commence later than in infancy, and as a sequel to other diseases.

In any inquiry into the true pathology of rickets we cannot afford to lose sight of the fact that the physiological processes of infancy are special in many ways. But of all the points in which they differ from the adult, none are more prominent than the inability to digest starch, and the rapid development of the bony skeleton. In the former lies the chief danger in artificial feeding by the uninformed, while it is on the latter that any cause of malnutrition, any change in the proper composition of the blood, will most tell. It is not at all necessary to search for any other reason why the bones are most and most often affected in rickets. They are the tissue which is most influenced, and is most permanently influenced by irregularity in nutrition—for they, as it were, fix any such change. And here we are brought face to face with the question which we asked some weeks ago, whether rickets is clearly specialised at all? Is there evidence of its being the result of a particular nutritive change, such, for example, as has been shown in connexion with scurvy? Is it not a condition of general debility producible by many different causes, but producing its main effects upon the bones which are the parts most influenced by the nutrition of the infant? Mr. HUTCHINSON threw out a suggestion consonant with this view that there may be a close relation between many different forms of disease of bones. It may well be the case, and it is a point to be carefully kept in view in the investigation of the subject. Meanwhile the debate on rickets has been of use, in showing that there are some points of general agreement, we had almost writen some points settled, and of still more use in showing how little of our knowledge is certain, how much is still mere conjecture, and that, common though the disease be, it has not yet lost the interest attached to all unsolved problems.

◆

THE chief event that has occurred during the year 1880 to interest ophthalmologists is the establishment, under the able presidency of Mr. BOWMAN, of the Ophthalmological Society of Great Britain—an event to which we referred last week. The International Congress of Ophthalmology met at Milan in September, and was attended by a very large number of ophthalmic surgeons. The president was M. QUAGLINO. M. JAVAL exhibited a new ophthalmometer, LORING an instrument for measuring the curvatures of the cornea, and PFLUEGER one for estimating the sensibility of the retina for homogeneous light. Many papers were read; amongst others, one by M. MEYER on Opto-ciliary Neurotomy, which he recommends in some cases in place of enucleation; others were by SECONDI on Detachment of the Retina, by DOR and LANDOLT on Daltonism. The Ophthalmological Section of the British Medical Association met at Cambridge under the presidentship of Mr. BOWMAN, and was well attended. Interesting papers or discourses were delivered by Professor DONDERS, Dr. BRAILEY, and others; whilst the discussions on Glaucoma and the treatment of Cataract were unusually animated and instructive. In regard to ophthalmological literature, a new journal in the French language, devoted to ophthalmology, the *Archives d'Ophthalmologie*, has appeared, under the editorship of MM. PANAS, LANDOLT, and PONCET. The first number contains several good papers, and it may prove a formidable rival to the well-known *Annales d'Oculistiques*. Amongst the more important treatises that have been published, either at home or abroad, may be mentioned a very complete and well worked-up treatise by KLEIN; a translation by Dr. LITTON FORBES of WECKER'S "Ocular Therapeutics"; a work by ROBIN, entitled "Troubles Oculaires"; a treatise on Wounds of the Eye, by M. YVERT; and an instructive series of lectures by Dr. ADOLF ALT of Toronto, on the Normal Anatomy and the Pathology of the Human Eye. Dr. GOWERS has made an important addition to ophthalmic literature in his work on ophthalmoscopy, and v. GRAEFE and SAEMISCH may be congratulated on the completion of their great Handbuch. Lastly, SCHUBERT has published a pamphlet on Syphilitic Affections of the Eye, based upon observations made in the clinic of HERMANN COHN of Breslau, in which the reader will find a good account of the various superficial and deep-seated affections of the eye associated with that disease. REMBOLD has contributed a paper on the condition of the pupil in various diseases of the central nervous system to NAGEL'S *Mittheilungen*. In M. SOUS' "Traité d'Optique" the general relations of optics to the eye and to the ophthalmoscope are given in detail. Several new ophthalmoscopes have been proposed. One by Mr. COUPER, of neat construction, in which the mirror can be shifted to any point of a circle of small lenses, and is at the same time made to swing on an axis, so that the reflection of the lamp can be more easily and fully directed into the fundus of the eye of the patient. His case contains two such instruments, one fitted with convex, the other with concave lenses. M. PARENT has constructed another very complete instrument, consisting of a small obliquely-set mirror of four- or five-inch focus, a set of convex and a set of concave lenses arranged concentrically, a set of astigmatic glasses, and a small sector having a stenopæic slit, and an optometer of Scheiner. The only disadvantage of this very serviceable instrument is the thickness of the successive discs through which the observer has to look. Various papers have been written on the anatomy and physiology of the eye. The most recent, and in some points of view most remarkable, statement is that just made by DENISSENKO of St. Petersburg, to the effect that the fovea centralis of the human eye, contrary to the opinion of most histologists, is traversed by many bloodvessels. These are situated in the molecular layer, but are not found at the exact central spot. The number of the nerve-fibres contained in the optic nerve, and of the rods and cones in the outer layer of the retina, has been the subject of laborious examination by SALZER, who finds that the absolute number of nerve-fibres contained in each optic nerve to be in round numbers 438,000. The number of elements contained in the rod and cone layer, which is much more difficult to determine accurately, varied from three to more than three and a half millions. From a comparison of the maxima and minima he arrived at the conclusion that each optic nerve-fibre gives origin to at least three, and probably to seven or eight, retinal elements. The structure of the retina has been made the subject of careful comparative study by DENISSENKO, the subjects of his observations being fish, birds, and mammals. SCHUELLER demonstrates that the retina is nourished by two sets of capillaries. The proper retinal vessels, which are branches of the arteria centralis retinæ, supply the fibrous and ganglionic layers of the retina and the anterior or internal granular layer. The posterior or outer half of the retina is nourished by the choroidal vessels. SAMELSOHN, from a careful microscopical examination of the optic nerves of a patient whose case he had followed in life, shows that the fibres which supply the macula lutea occupy the centre of the optic nerve at the foramen opticum, and as they pass forwards to the bulb become more laterally and externally situated. GUDDEN has described with great minuteness the decussation of the nerve-fibres in the chiasma. AYRES has examined the vision purple, and obtains it readily by immersing the retina in a 10 per cent. solution of common salt, and then a 2·5 per cent. of a solution of bile. Vision purple strongly resists putrefaction. HEISRATH finds that no such canal as that named "Fontana's" exists. The so-called space is really situated in the angle of the anterior chamber between the iris and the cornea, and is filled with connective tissue. Schlemm's canal, on the other hand, is really a canal, and is a part of the plexus ciliaris. Its inner wall is loose, and permits a free passage to the fluid of the aqueous humour. SCZELKOW has instituted certain experiments which have extended over eight years, to determine whether the curvature of the cornea undergoes any alteration with age, and has arrived at a negative conclusion. The presbyopia of advanced years, therefore, is essentially due to the well-known changes in the form of the lens. BEAUREGARD has studied the histology of the vitreous, but his results, whilst negativing those of former observers, establish but little that is new. PESCHEL describes a new entoptical phenomenon which may be observed when a gas flame is looked at through a deep red glass. A rounded heap of bright irregularly confluent points may then be sometimes seen which undergo certain changes, which he attributes to the action of light on the protoplasm, and which suggests that similar changes in the protoplasm accompany every act of vision. The rapidity of accommodation in the human eye has been determined by SCHMIDT-RIMPLER, who finds that with the same convergence of the visual axes the maximum degree of accommodation occupies 1·64 seconds. The value of the myotic agent, eserine, is becoming daily more and more recognised. The small gelatine discs, now in common use, are extremely valuable in various affections of the eyes. In the first place, in cases of wounds of the cornea near the sclero-corneal junction by contracting the pupil, eserine proves very effective in preventing prolapse, and it is not improbable that it may lead to the reintroduction of the old method of operating for cataract without iridectomy by lessening the danger of prolapse of the iris. In the subacute forms of glaucoma it is often of the greatest service in effecting diminution of the intraocular pressure, with relief of all the symptoms, within the space of a few minutes. It acts essentially on the peripheral branches of the third nerve, but apparently in part as a vaso-motor stimulant, causing contraction of the blood-vessels, and hence a diminution of the fluids in the eye; in part by contracting the pupil, and thus allowing a larger surface of the iris to be applied to the capsule of the lens, practically shutting off the posterior from the anterior chamber; and in part also by opening out the angle of the anterior chamber, and thus permitting a more free drainage of the aqueous humour. It has been warmly recommended by various authors in cases of keratitis and of ulcers of the cornea, especially of the asthenic form, its good effects being referred in part to a stimulant action on the supposed trophic nerves. It has been also found serviceable in cases of idiopathic and of induced mydriasis, and in asthenopia consequent on debility of the muscular apparatus of accommodation. The subject of Colour-blindness is yearly attracting more and more attention. The works of HOLMGREN, COHN, MAGNUS, and MICHEL in Germany, of JOY JEFFRIES in America, of DONDERS and BOUVIN in Holland, of FAVRE and DOR in France, of LUBINSKI in Russia, WOLFE and others in England—all of which have been published during the last year or two,—have demonstrated incontestably the immense responsibility which rests on those who have to control their actions by signals, and the necessity that exists for proper examination and testing of the vision of such officials. There can be little doubt that many of the apparently unaccountable accidents that from time to time occur result from this natural imperfection, and might be avoided in the future if such men were eliminated from a service for which they are physically unfit. Thoughtful papers have been contributed to the pathology of Glaucoma by Dr. BRAILEY and PRIESTLEY SMITH. Great praise is due to Dr. BRAILEY for having shown by careful sections that the condition of the structures forming the angle between the iris and the cornea exercises a potent influence in many cases in the production of glaucoma, for when from any cause the iris and the cornea become adherent and the loose connective tissue normally occupying the angle is obliterated, the drainage of the eye is interfered with, and owing to continued secretion of the aqueous, increased tension is produced, which may easily pass into glaucoma. It is easy to see how the operation of iridectomy and sclerotomy relieve this condition; PRIESTLEY SMITH, admitting the narrowing or closure of the angle of the anterior chamber, attributes glaucoma essentially to enlargement of the lens. HORSTMANN has made a special study of the ophthalmoscopic appearances and functional activity of 3581 myopic patients, and finds that in 1159 cases no visible change was perceptible, while 1683 presented a posterior staphyloma. The acuteness of vision when properly corrected with glasses was normal in the great majority of cases, but in about one-sixth of these cases it was reduced to one-half. Choroiditis, cataract, and detachment of the retina, strabismus, nystagmus, and, rarely, spasm of accommodation were the affections chiefly noticed. NETTLESHIP has described a series of cases of primary keratitis of a peculiar nature affecting the eyes of elderly persons and resulting in the deposit of a crystalline precipitate beneath the epithelium. This form of the deposit is that of a band running horizontally across, but never quite reaching, the periphery of the cornea. It is not unfrequently associated with glaucoma and iritis, and is incurable. Lastly, NEFTEL, KNAPP, AGNEW, and WEBSTER in America, have all directed attention to the possible cure of Cataract by electricity.

◆

THE faith in local self-government must, indeed, be robust if it remain unshaken by the recent and continuing experience of our political and social palladium as it affects vaccination and small-pox in the metropolis. The very genius of muddle seems to have possession of the metropolitan local authorities in relation to these subjects. Presumed to have the function of preventing, actually they contrive to foster the loathsome disease from which the public would escape, but, as the law stands, have no chance of escaping, except through them. Scarcely has one epidemic passed than we are threatened with another, and learn that in the short period between the ending of the one and the beginning of the other, and notwithstanding our recent experiences of the disease, the duties of the vaccination authorities, if not egregiously neglected, have been apathetically performed. The sanitary authorities keep the vaccination authorities well in countenance; the veneer of sanitary avocation laid upon the hospital authority being largely repudiated by them, while at the same time it is made use of as an additional argument for evading the duty which the hospital authority was empowered to aid them in doing. So that during the period when we should have been most active and energetic in carrying out measures for obviating epidemics of small-pox, our efforts were relaxed, and the conditions permitted to grow up under which our local epidemics of the disease arise. It is in vain the Local Government Board has appealed to the several authorities (even so recently as last week to the sanitary authorities) to recognise the common ground of action which underlies this multifariousness of authority. The appeal has fallen largely on deaf ears, for is not the action of the Central Authority a fair copy, and at the same time a justification, of the narrowness of action of the local authorities? With the Local Government Board small-pox in the metropolis, whether on the vaccination side or the public health side, is, above all things, a Poor-law question; and it would be a sin against all the proprieties of departmental administration, apparently, to deal with the question of the recurring prevalence of small-pox within the metropolitan limits,—of its relation to the state of vaccination, of the provision for isolation in hospital, and, incidentally, of the part which such isolation may play in the extension of disease in the neighbourhood of hospitals,—as if mere provincial small-pox, or even typhoid, or diphtheria, or scarlet fever, &c., which have no special relations with Poor-law administration, were in question.

And here we come upon confusion worse confounded. If it be desired (as it is by many) that local self-government in this matter should be replaced by central government, it should be obvious that the metropolis would merely be stepping from the frying-pan into the fire. Moreover, while we are tolerably familiar with the conditions found in the frying-pan, it is by no means certain that we can forecast (although the experience of the frying-pan and the grumblings therefrom augur the worst) the conditions of the fire. Even local self-government, miserably as it has muddled and still muddles in the metropolis the subjects under consideration, would be a less evil than a central government, which might be possessed of inexhaustible crotchets, and which regards public health matters in the metropolis after a fashion informed by the habits and traditions of Poor-law administration: in other words, a form of administration which, having in sanitary and public health matters failed disastrously in regulating even a workhouse, is held to be equal to the public health requirements of the whole metropolis.

And so it comes to pass—thanks to the apathy of the vaccination authorities, the shortcomings of the sanitary authorities, the anomalous position of the hospital authority, the perverse administrative lop-sidedness of the Local Government Board, and the general want of coördination of these authorities—that the metropolis is permitted to drift regularly into these epidemic extensions of small-pox. Add to the above considerations the negligence of the public in the intervals of epidemics both of vaccination and revaccination, and we have a picture before us which might daunt the most enthusiastic efforts for the betterment of the metropolitan population in this direction.

How far the state of things here indicated may be amended by improved arrangement of the local government of the metropolis, we do not propose to consider here, although we look to such amendment as a primary measure in getting things into better order. We look also to the merging of the peculiar legislation in public-health matters which governs the metropolis in the general public-health legislation of the kingdom as another important step in this direction—a step which would probably relieve the Local Government Board from the anomalous position in which it certainly stands as Central Health Authority in relation to the metropolis. We have to look to the immediate conditions of the case, and to consider in what manner the proceedings of the vaccination and sanitary authorities may, in existing circumstances, be best excited to a healthier action, and the public brought to a keener sense of their position in the matter. We concede that the Local Government Board (as things are) is, perhaps, doing all that can be reasonably required of it in this direction, with one glaring exception. The exception refers to "animal vaccination," so-called.

It is now four months ago since the President of the Local Government Board promised, in the House of Commons, that his department should make arrangements for the cultivation and issue, subject to certain restrictions, of animal lymph. There is good ground for the belief that such issue would overcome much friction in carrying out the vaccination law, and conduce to the greater freedom of revaccination, a consideration of hardly less importance than primary vaccination in the present state of vaccination among the population, and in view of an impending epidemic of small-pox. What has become of Mr. DODSON'S promise? Certainly it has not, to the present time, been performed, and for all that is known to the contrary outside Whitehall it might have been forgotten. It was contemplated, in the first instance, we believe, to start the English supply and cultivation of animal lymph from an original case of cow-pox, a determination much to be approved at the time the promise was given, but which necessarily postponed the carrying out of the promise indefinitely. Original cases of cow-pox appear to be of the rarest in England at present, and if any case had been discovered it is unlikely that the knowledge would not have reached the public ear. But the increase of small-pox in London and the threatening of an epidemic materially alter the state of the case, and lead us to ask whether Mr. DODSON can properly any longer delay the performance of his promise to an indefinite future. Surely in the face of an epidemic, and having regard to the importance attached by many to the use of animal lymph, it is time to forego, at least for the moment, the intention of starting from a new source, and to avail ourselves of the sources of lymph already in existence. We trust that Mr. DODSON, when Parliament meets, will be able to make a satisfactory statement on this matter; not only as to the delay which has taken place, but also as to his Department having been fully alive to the importance, in view of a threatened epidemic, of the early fulfilment of his promise to issue animal lymph.

Annotations.

"Ne quid nimis."

THE NAVAL MEDICAL SERVICE.

WE would gladly have had it in our power in our annual summary to congratulate the Naval Service on a more favourable progress of its medical affairs through the past year than that which we presented. It would certainly seem no difficult matter to have equalised its position before now with that of the Army Medical Department. With that view a committee sat through April and May, and although it dragged its slow length along, yet after a time it did send in its report, which has, we understand, with similar tardiness been adopted. It is said that a new Warrant is now actually in print, and that it comes up in most respects to the late Army Warrant, being in some particulars even more liberal, as it gives 11*s.* a day to its students at Netley, while those of the Army have but 8*s.* a day; it gives permission to retire after twenty years' service, and a better scale of retired pay to fleet surgeons of twenty-five years' service, who have attained fifty years of age, when they will be compulsorily retired on 30*s.* a day, the same as is awarded to Brigade-Surgeons of the Army of thirty years' service. It will be at least pleasing to many junior members of the profession to learn this, and further that, according to the latest rumours, these conditions will be made known previous to the ensuing examination in February.

LODGINGS AT THE UNIVERSITIES.

WE have to express our sincere sympathy with Mr. Haynes Walton in the great trouble that has befallen him in the bereavement of son and daughter from diphtheria; the former from the disease contracted in lodgings at Oxford, the latter falling a victim to her devotedness in nursing her brother during his fatal illness. Mr. Walton has stated the facts connected with the origin of his son's illness in a letter published last week; and the Rev. G. S. Ward, delegate for licensing lodgings, has replied to the charges urged in this letter with frankness and courtesy. Mr. Ward's letter, however, makes one thing plain, that the system of supervising the sanitary arrangements of the lodging-houses at Oxford is very far from perfect, and the University authorities have undoubtedly incurred a very grave responsibility in the neglect of adequate sanitary precautions in the present instance. It appears from Mr. Ward's letter that after the lodgings had been put thoroughly in order under the supervision of the sanitary officer of the City of Oxford, three years were allowed to elapse before any further inspection was made, and during that time no complaints were offered by the occupants—that is to say, the inspector of lodging-houses apparently waits till the sanitary arrangements again break down, and complaints are made, before instituting another inspection. Surely it ought to be a recognised duty to see that the sanitary arrangements of each licensed lodging are in thorough repair and working order before the commencement of each term. In saying this we do not wish to bear hardly on Mr. Ward; doubtless the means at his disposal are quite inadequate to insure a periodical sanitary inspection of each licensed lodging in the City of Oxford, and we are ready to admit, judging from his letter, that he has really endeavoured to do his duty in the position in which he has been placed. The whole blame rests with the University authorities who have established such a sham and inefficient system of sanitary inspection, and it is to be hoped that the present catastrophe will not be without salutary effect in inducing them to appoint a staff of efficient and specially trained officers to undertake a systematic supervision of all licensed lodgings. The sanitary officer of the city should be requested to make a thorough inspection of each lodging once a year, whilst an inspector of nuisances ought to visit it just before the commencement of each term to endorse the licence, supposing he found everything in working order. No student should be permitted to take lodgings unless the licence had been so endorsed. During term time the inspector should be directed to pay frequent visits to the lodging-houses, in order to ascertain that no obstruction had occurred in the house-drainage, and that the ventilating-pipes, traps, &c., were all in working order. Some such scheme is imperatively demanded, and it is quite certain that the present perfunctory system can be no longer tolerated in this age of sanitary light and science. These remarks apply with equal, if not greater, force to the same system at the sister university, Cambridge.

“GEORGE ELIOT.”

“GEORGE ELIOT” is dead. To her intimate friends she was a prophet; to the public she was one of the most remarkable women of her generation; and looking at her large and varied knowledge, at her great intellectual powers, at the breadth and depth of her sympathies with human life and character, at the strength of her imagination, and the whole scope of her genius, it is perhaps not too much to say that she was one of the most remarkable women of all the generations that have gone before. “George Eliot” is dead; and as there will be on the part of our readers a natural, and, indeed, pardonable curiosity to know something of the illness which ended in her death, we subjoin a brief narrative of the facts as they have come to our knowledge.

On Dec. 18th “George Eliot” was present at an afternoon concert, which she much enjoyed. In the course of it her husband, Mr. John Cross, noticing that the place in which they sat was somewhat draughty, proposed to throw her shawl over her shoulders, but she declined the attention with the remark that it was very hot. On Sunday afternoon she felt a little chilly, but was yet well enough to receive and entertain Mr. Herbert Spencer and the other friends who visited her on that day. On Monday morning she was ill, and Mr. George Welland Mackenzie, summoned to see her, found her in a somewhat feverish condition, with symptoms of laryngeal catarrh. On Tuesday morning the laryngeal trouble had almost disappeared, but she was still a little feverish and complained of pain in the right lumbar and iliac regions, but not so severely as she had often felt it before. On Tuesday evening, although both laryngeal catarrh and lumbar pain were almost gone, the patient was not so well. Her breathing was frequent and she was restless and uneasy. The temperature, however, was not above 100°, and a careful examination revealed no signs of fresh local mischief. On Wednesday morning the patient was still worse. There was considerable prostration, the breathing was hurried, the face was grey and anxious, and there was general but indescribable uneasiness. Again Mr. Mackenzie made a careful examination without discovering any fresh local complication, which he was anticipating from the increasing gravity of the symptoms. At this time Mr. Mackenzie explained to Mr. Cross the perilous condition of the patient, and his fears for the issue of it. It had been arranged beforehand that Dr. Andrew Clark should visit Mrs. Cross on that evening at six o'clock, and when he arrived Mr. Mackenzie communicated to him the state of affairs as they existed in the morning. They then visited the patient together, and found that a somewhat sudden and still more serious change had occurred in the course of the afternoon. The patient lay on her back, with the shoulders raised. The eyes were closed; the face was of an ashen grey colour; the lips were slightly livid; the arms lay extended on the coverlet; the breathing was extremely hurried, but quiet, and on feeling the pulse, which was frequent, small, and irregular, the hand was found to be cold and clammy. Plainly now the heart was at fault, and on placing the stethoscope upon the chest, a loud to-and-fro friction was heard throughout the whole cardiac region. The patient was too ill to be further disturbed. Attempts were made to give food and brandy, but they were in vain. Death was evidently near at hand, and the heart rapidly failing; there was complete unconsciousness, and she ceased to live about ten o'clock.

Although the death of this illustrious woman appears to have been thus so painfully sudden, it was not so in reality; for, so to speak, preparation was being made for it during the last eight years. In 1873, on account of the cessation of a uric-acid deposit, and of attacks of pain in the right side and groin, Dr. Clark inferred the presence of a uric-acid calculus in the kidney. In 1874 there were two or three attacks of renal colic, with hæmaturia. In 1876 Mrs. Cross had an attack of cystitis, and was seen by Sir James Paget and Dr. Andrew Clark together. From that time until near the close of life there had been several attacks of pain, sometimes with and sometimes without hæmaturia. In the course of the year 1880 the urine had steadily fallen in density, and contained sometimes albumen, sometimes pus. In October last, Dr. Andrew Clark saw Mrs. Cross at Witley, in consultation with Mr. Parsons, when she was found to be suffering from symptoms of slight calculous pyelitis.

During the last few years, therefore, “George Eliot's” general health had been visibly failing. She was less capable of sustained work, more easily deranged, and liable to sudden illnesses from small causes. The organism, well enough for the ordinary round of a quiet life, was unequal to any extra demand that might be made upon its powers of resistance and repair, and thus it was that a sudden chill brought it, unhappily, to a speedy end.

INFECTED MILK.

WE have been favoured by Surgeon-Major Jameson with the following particulars relating to the outbreak of typhoid fever at Portsmouth Barracks. Instances of the spread of disease by infected milk are becoming numerous, and the account of an outbreak of enteric fever in the Cambridge Barracks may prove interesting.

From Sept. 30th to Oct. 10th, 1880, seven cases of enteric fever appeared. An officer's wife, two children, and a nurse, living in the officers' quarters, the wife of a colour-sergeant, and two children of a private soldier, living in the married quarters of the regiment, were attacked. The sanitary condition of the barracks is good, and on careful examination by the Royal Engineer Department no defects could be discovered. The fact was elicited that all the people affected received their milk-supply from a certain dairy on the Gosport side of the harbour. A specimen of the suspected milk was analysed, and pronounced a fair sample. It was, however, deemed advisable to discontinue the use of the milk in barracks. No more cases occurred.

On October 14th Major R—— visited the milkman's house, and ascertained that his son had been suffering from some kind of fever for several weeks, and was then recovering. The medical man in attendance said he was not prepared to say it was a genuine case of typhoid fever, but admitted there were typhoid symptoms. The house in which this patient lived was one in a row. He lay in a room upstairs. Everything, such as stools, &c., had necessarily to be carried through a back kitchen, which was used as a sort of dairy; for at the time of his visit Major R—— saw milk standing there. There was no properly-constructed dairy whatever, and no other room was used for the purpose. The house had no watercloset, but a privy at the further end of a small garden, in a very offensive condition. The water from the Gosport Water Company was laid on. The water tap was placed above the opening of a drain, which, leading to the privy, was carried on to the cowshed. The typhoid infection may have been absorbed by milk standing in the same apartment as that through which stools were conveyed, or perhaps temporarily deposited. The act of milking also may be highly dangerous in a person in attendance upon a typhoid patient. In the officer's family all the people attacked were in the habit of taking a glass of milk at night before going to bed. The officer himself and two children took milk in tea very sparingly, and escaped. The symptoms of the disease in range of temperature, eruption, &c., were typical, with this exception, that diarrhœa occurred in one case only. In all the other cases constipation constantly required relief by mild enemata. Whether this constipation was accidental or influenced by milk infection is a subject which further investigation may elucidate.

WHOLE-MEAL.

THE problem of a truly economic supply of fully-nutritious bread is not to be solved by platform oratory, or made the subject of a new development of "woman's mission." It is simply a question of manufacturing ingenuity and trade-enterprise. The only difficulty is to grind the meal. We do not want chopped husks, but a finely pulverised flour, comprising the elements of the grain in their natural proportions. We do not believe that artificial combinations of the supposed elements of a normal "whole-meal" in arbitrary relations can compare with the natural food of man. There should not be any persistent obstacle to the supply of the complete flour required for making economic bread. The clumsy mills in use will not, probably, do the work required of them; but it cannot be impossible to devise a crushing apparatus that shall answer the purpose. In fact, there are many such employed in the trituration of other substances. It would be a regrettable circumstance if this matter, which is simply one of supply and demand, should be taken out of the category of everyday affairs, and placed on a sentimental footing under the hackneyed name of "reform"—a term much too freely employed nowadays, and seemingly the ready instrument of every agitator. The public do not stand in need of any special enlightenment on the subject. It has been over and over again demonstrated that the whole-meal contains elements of nutrition which are not to be found in common flour, and which are necessary to insure that the bread shall be easily digestible, and thoroughly good for food. The chemical and physical facts have been repeatedly stated, and are well recognised. The people will be only too glad to get whole-meal bread, when they can be furnished with an article which does not offend the sight by its needlessly dirty colour, and the stomach by its mechanically irritating constituents.

RAIN AND FOG.

THE relations between fog and rain ought to be better made out than they are if, as most persons seem to suppose, fog is simply vapour laden or charged with particles of soot. Is it a fact that fogs follow rain with anything like the constancy which should obtain if the conditions were as it is the fashion to state them? Mists are common enough, and everybody is familiar with the dense damp cloud, miscalled a fog, which every now and again floats in over the sea and enshrouds the channel in darkness. Vapours of similar constitution are common enough on land; but strangely, if we are to accept the popularised hypothesis of fog-production, they do not arise from, or in any marked degree associate themselves with, the most smoky districts! Nor are fogs shown to increase with the prevalence of coal-fires in any particular locality. "London fogs" have lost their distinctly yellow character since the Thames has been embanked, although the smoke nuisance has been developed superabundantly since the completion of this great metropolitan improvement. Those who are well advanced in the forties cannot fail to remember the genuine old-fashioned fog, which was considered to be one of the peculiar sights of London. When the visitor woke in the morning he found the panes of glass in his bedroom window apparently coated on the outside with a dense layer of yellow distemper, something like what is now seen in the developing-room of a photographer's studio. The glass was rendered so opaque that not even the sill outside could be recognised. This was a common phenomenon some forty years ago. Even in the worst fogs of recent date there has been nothing to compare with the genuine "London fog" for colour or substance. How should this change have come to pass if coal-fires were the cause of these visitations? The number of chimneys pouring soot into the atmosphere of London must have multiplied nearly 50 per cent., area for area, during the last half century. Many of the known facts about fogs point to a connexion between the surface-drainage and their production. Yet, if that seeming connexion actually existed, there should be some constant sequence of rain and fog. There *is* an obvious and easily-recognised relation between rain and mists, but not between rain and fogs properly so-called. The change of colour which is noticed in the fogs of recent, as compared with previous, times is probably, to some extent, due to the covering up of the yellow London clay by the extension of buildings. This points to the inference that it is with matters derived from the earth itself rather than from the atmosphere, fogs are laden. Before any hasty conclusions are adopted with regard to the mode and source of fog-production, it would be well if a few common-sense inquiries were instituted by practical geologists. It is vastly easy to charge the evil on the consumption of coal, but, so far as we can see, the ascertained facts do not warrant this line of inference. The question must be more carefully and scientifically investigated before it reaches a practical and safe settlement.

MEDICAL COLLEGES IN THE UNITED STATES.

ONE of the great evils of the medical system of America is the multiplication of medical colleges. Anybody can get up a medical college, with the terrible power of granting medical diplomas. No medical theory is too wild to justify the creation of a special college for its teaching. But unfortunately the evil does not end here. A letter in the *Missouri Republican*, published at St. Louis, divulges another bearing of the host of medical colleges in the cities of the Union. This letter is written by Mr. Charles W. Francis, the Health Commissioner, to Dr. D. V. Dean, superintendent of the City Hospital, and has reference to the privileges of the Medical Colleges as regards the *right of admission to the hospital*. Every Medical College, it seems, complying with the law, has the right of admission to the hospital for purposes of teaching, so that the unfortunate patients, after having been duly studied by a regular teacher and his class, are liable to be put through the same ordeal by the homœopathic teacher, to be again followed by the eclectic teacher, &c. The Health Commissioner points out that this privilege of medical colleges has become a huge nuisance alike to the officers of the hospital and to the patients, and he intends to propose to the city authorities a modification of the laws regulating this matter. We should say the sooner the better for the sake of medical science and of humanity. St. Louis has, we presume, fewer inhabitants than Leeds, and it has the following medical colleges:—The Missouri Medical College, the St. Louis College of Physicians and Surgeons, the St. Louis Medical College, American Medical College, Homœopathic Medical College of Missouri, St. Louis College of Homœopathic Physicians and Surgeons, and the St. Louis Eclectic Medical College. "We have not yet," says Commissioner Francis somewhat pathetically, "settled the matter as to Dr. Field's College being admitted to the privileges of the hospital, but if the college complies with the law, I will, under the city counsellor's opinion, have to let them in." We heartily wish Commissioner Francis quick success with his new regulations.

MR. JOSEPH COWEN ON VACCINATION.

MR. COWEN, the able though somewhat eccentric member for Newcastle, was lately asked by a deputation to support a Bill to be brought in by Mr. Peter Taylor, to abolish the compulsory clauses of the Vaccination Act. Mr. Cowen declined at present to go so far, but agreed to oppose the estimates for successful and efficient vaccination, and to support Mr. Dodson's Bill, if it should be reintroduced. Mr. Cowen added an argument and a statement which, we confess, surprise us from a man withal so sensible. The hon. member said he looked upon the practice of vaccination as unnatural, and that none of his children were vaccinated. So much the worse for his children we should say; and probably they will have to say so one day. But that is a private matter, and they are now beyond the reach of the law. His argument is a matter of public interest—that vaccination is unnatural. Does Mr. Cowen really mean by his legislative measures to take us back to a state of nature? Is this the end of civilisation? When he comes up from Newcastle by the Scotch Express in six hours, does he not do something far removed from the actions of his ancestors in a state of nature? When he puts on his clothes, is he not doing something which people in a state of nature do not bother themselves to do? In a state of nature an unvaccinated community takes small-pox in a proportion of 90 per cent., and of these 40 or 50 per cent. die in a most horrible state, which deters neighbours from humane and neighbourly attentions to them. Are we to be blind worshippers of a state of nature? If so, why the arts? or the sciences? or the Legislature? or any effort at all at improvement? Mr. Cowen is surely too honest and too sensible a man to adhere to such an argument. It is to be regretted that he has used it. He owes it to his own reputation either to justify it or to withdraw it. The most beneficent discovery of medicine deserves a more intelligent and grateful recognition from Mr. Cowen.

THE USE OF ALCOHOL IN HOSPITALS.

THE tendency to be ostentatious as to the use or non-use of alcohol in hospitals is to be discouraged. The therapeutical value of alcohol is a question not to be disposed of, one way or the other, by letters to the newspapers, or by a limited group of vague statistics, but by a very careful study of its use or non-use in individual cases. The most rigid teetotaller may well be satisfied with the growing tendency in physicians to use it strictly and to be satisfied only with distinct proofs of its utility; and the most generous believer in the medicinal virtues of alcohol must know that the public and individual patients are taking a keener interest in this question than they ever did before, and are making very shrewd personal experiments on the subject. Our own opinion concerning it has been freely expressed, and we have not concealed our conviction that good health is most consistent with very little alcohol or with none; that he who uses alcohol freely or frequently, or by itself and apart from food, is surely laying up disease and degeneration for himself, and probably for his descendants. But we may leave the use of alcohol in hospitals to physicians, who are under every inducement to do that which will show the best curative results. It is but very lately that we received from one of the London hospitals, in no way committed to extreme views, a wonderful revelation of the habits of many of the patients as regards the excessive use of alcohol. We may confidently believe that such revelations are studied by none more carefully than by the physicians and surgeons whose duty it is to treat disease with such antecedents.

SOME POINTS IN THE ANATOMY OF THE EAR.

IN a paper which has just appeared in the *Archiv für Anatomie*, by Professor Retzius, he states that as the great work of the anatomy of the ear on which he is engaged will take a long time to complete, on account of the trouble and expense of the engravings which are to accompany it, he desires to publish provisionally some of the new facts which he has discovered. In the first place, he some years ago found in the auditory labyrinth of teleostean fishes two small plates on the floor of the utriculus, near the canalis communicans, on which two branches of the cochlear nerve terminate. He considered this structure to be the first indication of the "pars basilaris cochleæ." Hasse acknowledged its existence in fishes, and thought it to be the rudiment or "pars initialis cochleæ." Further researches satisfied Retzius that it was present in the plagiostome fishes, and still more recent researches have enabled him to trace it through the amphibia, through many reptilia, in which it is less developed than in amphibia, and through the birds, where it is still smaller and more rudimentary than in reptilia, appearing only as a small spot with a few nerve fibres distributed to it, situated on the floor of the ampulla frontalis. No trace of it can be found in the rabbit, cat, or dog amongst mammals. He has, therefore, changed his opinion, and no longer regards it as the rudiment of the cochlea, but has named it the "macula acoustica neglecta," and the branch of nerve supplying it the "ramulus neglectus." How, then, he asks, does it stand with the true pars basilaris cochleæ—the most important part of the organ of hearing? Since this nerve termination does not represent it, it may be stated that in fishes there is no pars basilaris; they only possess the lagena cochleæ. The first traces of the true pars basilaris occur in amphibia.

A second point to which Retzius has directed his attention is the mode of division of the acoustic nerve. He quotes the descriptions given by Henle, Hyrtl, Luschka, Krause, Quain, and Turner. In the works of all these authors the auditory nerve is stated to divide into two chief branches —a ramus vestibularis and a ramus cochlearis. Some authors admit that the vestibular nerve divides into four branches, which supply the sacculus hemiellipticus and the three ampullæ; whilst the cochlear branch divides into two branches, which supply the sacculus hemisphericus and the cochlea. Others consider that the cochlear nerve only supplies the cochlea, and that the vestibular nerve gives off five branches. Neither of these statements is correct. The anterior of the two main divisions of the auditory nerve—that is to say, the vestibular nerve—which, by the twisting of the parts really lies posteriorly to the other, divides into three branches, which supply respectively the recessus utriculi, the ampulla sagittalis, and the ampulla horizontalis. The posterior main branch—i. e., the cochlear nerve—divides into three branches, which supply the ampulla frontalis, the sacculus, and the cochlea.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE pressure on our space last week prevented us noticing the very satisfactory meeting of the constituency of the Hospital Sunday Fund, at the Mansion House, under the presidency of the Lord Mayor. Though the day was very unfavourable the attendance was good, and the audience and the platform alike showed the hold which this movement has on the churches of London. The first resolution was moved by the Bishop of London, and seconded by Professor Marks, and similarly with most of the others. The utmost conciliation and consideration were shown in discussing the most suitable day for the purpose, and Sunday the 19th of June was agreed upon. Apart from the needs of the hospitals, which are very great, this institution is a positive blessing to the community by supplying an object at which men of all creeds can work together.

SUBSTITUTES FOR ALCOHOL.

MR. FRANCIS VACHER of Birkenhead publishes an experience of 243 cases of typhus observed in hospital, in which he thinks he obtained great advantages in treating patients requiring stimulants with such stimulating drugs as ammonia, compound spirit of ether, and camphor, with or without chinchona (using at times the tincture in small doses), as if he had used wine or spirits. In convalescence, moreover, he gave the preference to ripe fruit and malt extract to beer or porter. Mr. Vacher abstains from alcohol, and thinks that it would probably be all the better if the sick and the healthy would alike abstain. The question he deals with is a complicated one; but there are imported into it certain social and moral matters, which must necessarily affect the conclusions of the observer. Of the value of alcoholic stimulants in the treatment of typhus, *if a stimulant is required*, we imagine no question can well be raised. Is a medical man right, when treating a case requiring stimulants, to substitute for an agent of determined value agents which appear hitherto to have been shown to be of less value? In other words, are we justified in putting aside from a view of some possible prospective social gain a form of stimulant of approved value under certain circumstances for stimulants commonly had recourse to under other circumstances? Is the medical man warranted, in a question of life and death, in leaving unused, on grounds having no connexion with the welfare of his patient, one of the most potent items in his armament? We think not. Experiences like those given to the world by Mr. Vacher and his co-thinkers have their value, particularly in teaching that the use of alcoholic liquors in the treatment of disease ought to be as carefully regulated as the administration of drugs.

NETLEY HOSPITAL.

ATTENTION has been called, by a letter in *The Times*, to the neglect of the military authorities in not having the damage repaired which was done by the fire at Netley Hospital, in March last, to the rooms set apart for the treatment of sick and wounded officers returning from foreign service. It appears that of six rooms appropriated to this purpose, only one is now available. On the 15th December Major Godson, of the Madras Staff Corps, arrived at Southampton by the P. and O. steamer, very ill, suffering from abscess of the liver, brought on by service in Afghanistan. On application being made by his brother-in-law—an officer of the Indian Medical Service—to have him admitted as a patient into Netley Hospital, he was informed that this was impossible, as the only quarter available since the fire was occupied. The establishment of sick quarters for a limited number of officers was a well considered and kind measure, adopted in accordance with the recommendation of Lord Herbert's Commission, and it has proved a great boon to many sick and wounded officers who have arrived in England so ill as to be unequal to the fatigue of a land journey to their homes. It is much to be regretted that a delay of nine months should have occurred before any steps have been taken to put these quarters again in habitable condition, and to secure the boon of skilful treatment and careful nursing to officers returning home in the state in which Major Godson is described to have been. We trust that Mr. Childers will exert his power as War Minister, and order the necessary repairs to be done at once upon his own authority, without waiting for that period to which in the Army so many necessary works and repairs are postponed, and which is described in official language as "to be included in the next year's estimates."

THE TENT-HOSPITAL CASE.

WE regret to say that judgment has been given against the plaintiff in the case of Eaton *v.* Barker and others, heard before Mr. Justice Stephens in the Court of Exchequer. The plaintiff, it will be remembered, is a medical man, who undertook the charge of the tent-hospital erected lately at Grantham, to meet an outbreak of scarlet fever. He charged himself with the duty under an agreement made with a committee of the local authorities then concerned, through their medical officer, Dr. Ashby. When the outbreak was over, and his duty at the hospital ended, he presented an account, according to his agreement as to fees, for £97 7*s.* 9*d.* Meanwhile the authorities originally concerned in the agreement had amalgamated and been formed into a Corporation; and when the account came before the newly organised body, the necessity of the case being over, the sum total was objected to. Mr. Eaton declined to accept a less sum, and sued the Corporation. The Corporation then took advantage of a technical objection, to wit, that under section 174 of the Public Health Act agreements involving sums of over £50 must be entered into by the agreeing authority in a particular manner, and this manner had not been followed in this case. The objection was held by Mr. Justice Stephens to be good, but its bearing upon the case is best expressed in his own words :—

> "It appeared clear to him that the Board resisted a moderate demand for payment earned by a man who discharged a public duty at the risk of his health and practice. They founded their defence on a ground of the most technical character, and which had nothing to do with the merits of the case. He did not, however, feel himself at liberty on that account to deprive them of the costs to which in the order of things they were entitled. If the defence was legal, it was not for him—he did not say that in any other circumstances the facts might be considered—but speaking for himself, it was not for him to say that the mere fact that in his opinion the defence ought not to have been set up, ought to lead him to deprive the successful party of their costs. Judgment would therefore be given for the defendants with costs."

The condemnation of the course taken by the Corporation could not well be expressed in stronger terms. It remains to be seen whether the people of Grantham will allow Mr. Eaton to be thus deprived of his legitimate fees, and mulcted also of the costs of the proceedings. If they do, it will be incumbent upon the profession to interfere in his relief. Medical men in future will, if they are wise, refuse, under the pressure of an epidemic and the alarm of a community, to make any terms with a local authority involving money considerations, except through a solicitor.

THE LATE AFGHAN WAR.

THE Army Medical Officers who have taken part in the recent Afghan war have, we understand, expressed a desire to commemorate the services of the Medical Department in the various expeditions in Afghanistan by some permanent memorial. It has been decided that this is to take the shape of a piece of plate for the Officers' Mess, Army Medical Department, Aldershot. Surgeon-Major G. C. Markey has undertaken the duties of honorary secretary and is collecting subscriptions from officers in India. We hail with satisfaction this evidence of *esprit de corps* amongst medical officers, and as the Indian Government have treated the troops employed in Afghanistan with liberality in the way of allowances and batta, subscriptions and donations will not be felt a heavy tax. The Medical Department played no inconsiderable part in the Afghan war; many officers returned with health more or less shattered; many succumbed to exposure, climate, and disease; one and all did their duty fearlessly and conscientiously in the face of innumerable difficulties. It is fitting therefore that there should be a lasting tribute to their services, and the medical officers at Aldershot will justly prize the honour of having the memorial committed to their keeping.

PATHOLOGICAL SOCIETY OF LONDON.

THE annual meeting of the Pathological Society will be held on January 4th. In addition to the regular business of the Society, the officers and Council for the ensuing year will be elected, and the annual report and statement of accounts read. The following is the list of nominations by the Council :—President: Dr. Wilks. Vice-Presidents: Drs. George Buchanan, Thomas Buzzard, Andrew Clark, James E. Pollock; Messrs. Christopher Heath, Jonathan Hutchinson, S. James A. Salter, Septimus William Sibley. Treasurer: Dr. George Johnson. Honorary Secretaries: Dr. Joseph Frank Payne, Mr. Henry Morris. Council: Drs. Thomas Barlow, E. B. Baxter, J. Cavafy, S. Coupland, Sir Joseph Fayrer, Wm. Ord, Douglas Powell, G. H. Savage, F. Taylor, T. Whipham, W. B. Kesteven; Messrs. W. Morrant Baker, J. N. C. Davies-Colley, Warrington Haward, H. Howse, Joseph Lister, R. W. Parker, W. J. Smith, Waren Tay, W. J. Walsham.

THE MEDICO-SANITARY SERVICE OF THE PANAMA CANAL.

DR. LOUIS CAMPANYO, who was at the head of the medico-sanitary service of the Suez Canal during its construction, has prepared for M. le Comte de Lesseps a scheme for the organisation of a medico-sanitary service of the Panama Canal. This scheme, which is published in a separate work by Baillière & Son of Paris, will be read with much interest. After a general account of the topography, geology, meteorology, &c., of the isthmus at the point where it is proposed to cut it through, the auther describes in detail the organisation of a health-staff, but rather for the medical and surgical requirements of the case than from the strictly *sanitary*, as we should use the phrase here. The projected organisation for the feeding and the sickness of the labourers is discussed at considerable length, and much is said about ambulances and sick attendants. Vaccination is not forgotten; pharmacy and the surgical armament are duly considered; fire-extinction has a place with reference to the ambulances; cemeteries and sepulture are not overlooked; even prostitution and its consequences are regarded. In addition, a veterinary service is considered. But the condition of habitations of the healthy men, and the arrangements for the disposal of liquid and dry refuse about the habitations, have but the briefest consideration. In this respect the project of organisation differs remarkably from that which an English medical-sanitary authority would probably have prepared. Nevertheless, Dr. Campanyo's scheme contains very much that is instructive, and is accompanied by many suggestions that may be turned to good account, irrespective of the gigantic enterprises—one completed, the other now in a fair way to be completed—out of which they have arisen.

A JUST DECISION BY A COUNTY COURT JUDGE.

AN important case (Bell *v.* Parkinson), and one which has excited considerable interest, was concluded in the Bradford Count Court on Dec. 18th, before W. T. S. Daniel, Esq. (judge), and a jury.

Early in 1879 Dr. Bell attended Mrs. Parkinson in confinement, and, being a delicate woman, her recovery was somewhat protracted. In course of time Dr. Bell sent his account of £8 7*s.* 6*d.* for professional services, and when defendant was pressed for payment of the same he brought in a counter-claim of £50 against plaintiff for negligence. It was alleged by nurse Willis (a trained nurse) that a portion of the placenta had been left behind, which she removed. However, in cross-examination, she said she had thrown it away, whereupon the judge observed that an important link was wanting in the evidence. Ultimately, after an admirable summing up by the judge, the jury returned a verdict for Dr. Bell, and condemned the defendant in costs for both actions.

MEDICAL PRETENDERS IN NEW ZEALAND.

THE *Rangitikei Advocate* and the *Manawater Herald* contain reports of the trial of two persons for the false use of medical titles, named respectively Frederick Lyster and John Frederick Rockstraw. Both were found guilty, and both were fined—Lyster £50, and Rockstraw £25. Our contemporaries, in commenting on these verdicts, approve them, but object to the heavy fines imposed, especially on the ground that the Medical Act of the colony had in these parts been allowed to remain a dead letter. This is a point of detail on which we have no wish to differ from our contemporaries; but we can imagine nothing more necessary in a colony like New Zealand than for the authorities to be careful, and even severe, in punishing false pretences. In old societies there is less difficulty in distinguishing the regular doctor from the pretender, though even in such communities Medical Acts are very essential. But in a colony, if the authorities are careless, any useless impostor, or incapable druggist, may set up as a doctor, and in a critical emergency, by a false title, fatally mistreat a citizen. The offence is a very serious one, and ought to be most severely punished.

THE Marquis of Bute has intimated his intention of presenting a valuable new site for the Cardiff Infirmary, four acres in extent, and estimated to be worth from £10,000 to £12,000, which site his lordship has to purchase from the executors of the late Lord Bute's will. In addition to this noble gift his lordship is a donor of £1000 towards the Building Fund. The architect of the new buildings is Mr. A. P. Bell of Manchester. It is designed, in the first instance, to accommodate 100 patients, with administrative department sufficient to allow of a future extension to 200 beds. The site is admirably selected, and, when completed, the new buildings will add one more to the noble institutions which are springing up in this rapidly-growing town and neighbourhood. The estimated cost is £21,000, towards which nearly £13,000 has already been promised.

H.R.H. PRINCE LEOPOLD honoured the wedding of Mr. Arnold Royle, M.R.C.S., Surgeon-in-Ordinary to His Royal Highness, and late Assistant-Surgeon Royal Artillery, by his presence at the marriage ceremony in St. James's, Piccadilly, on Dec. 20th, 1880. The bride is the second daughter of Thomas Snow, Esq., Barrister-at-Law, Liverpool. Wedding gifts were presented by their Royal Highnesses the Prince and Princess of Wales, Princess Louise, the Duke and Duchess of Connaught, and Prince Leopold, to the happy couple.

DR. GEE, Physician to St. Bartholomew's Hospital, has recently had under his care in the wards a girl, seventeen years of age, with chorea, for which chloral hydrate in frequently-repeated doses was prescribed. During the third week of its administration, a papular eruption of a dusky hue, surrounded by much cutaneous redness, was produced on the forehead, face, chest, and extremities, in arrangement partly crescentic, and partly confluent. The eruption consisted essentially of a combination of lichen and erythema papulatum, and was attended with some increase of temperature.

WE may expect to hear of the Nursing question giving trouble in our Transatlantic dependencies. The authorities of the Toronto hospital are, it is stated, about to establish a scheme for training nurses, their instruction to be undertaken by a lady graduate of one of the schools of England. We hope the experience so dearly bought in the mother country will not be lost on the promoters of the enterprise in the far west.

THE School of Medicine and Surgery of Montreal has caused a protest to be served on the authorities of the Laval University at Quebec, calling upon them to cease their branch in the former city, and threatening legal proceedings if the protest is disregarded.

DR. J. J. LUCE, of Stratford-on-Avon, has, we regret to learn, met with an accident of a serious nature. Whilst out driving on Tuesday last the horse took fright, and the gig coming in violent collision with a building, Dr. Luce was thrown out and sustained severe injuries of the head and various parts of the body.

AT a public meeting held at Dundee last week, Dr. John Boyd Baxter intimated that he intended giving £125,000 for the establishment in Dundee of a college similar to Owens College, Manchester. Later information attributes the bulk of this gift to the generosity of a lady of the same name. An effort is to be made to raise a similar sum by public subscription for the endowment of the College.

MR. CÆSAR HAWKINS will preside at a meeting, to be held in the Board-room of St. George's Hospital on Jan. 11th, having for its object the promotion of a testimonial to Mr. G. D. Pollock, on the occasion of his retirement from the post of senior surgeon to the hospital.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Diphtheria in the Hospital for Sick Children, Great Ormond-street.—This report appears to have been issued by the Medical Department of the Local Government Board as an illustration of their failures (to use Beau Nash's "gentleman's" phrase). In March of the present year the patients in the Hospital for Sick Children suffered from an unusual outbreak of diphtheria. Diligent search at the moment failed to elicit a sufficient explanation of the outbreak, which was pretty general throughout the hospital, and aid for help in prosecuting further inquiry was asked from the Local Government Board. Mr. W. H. Power, whose acumen in pursuing researches of this task is well known, and who has already distinguished himself by unravelling obscure outbreaks of diphtheria, was instructed to give the required help, and his report of the course he pursued in carrying out the directions of his Board and the wishes of the hospital authorities is now before us. The report is simply exhaustive so far as our present knowledge of the habits and conditions of prevalence of the disease extends; but he has to confess that it not only gives no explanation of the outbreak, but also furnishes no clue which promises an explanation. Failing such explanation or the clue to one, the report is of special value as showing the state of our present knowledge of the conditions under which diphtheria is likely to prevail, and brings out in a clear sharp light that there are still other conditions of the prevalence of the disease of which we have as yet no knowledge, and of which we have to construct a reasonable hypothesis before we can hope to obtain the knowledge. As an incentive to the construction of such hypothesis Mr. Power's report is invaluable, and we commend it to those members of the profession interested in etiological inquiry who have yet to win their spurs.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Lambeth.—Dr. Archer Farr reports for 1879 a birth-rate of 34·6, and a death-rate (strangers included) of 21·6 per 1000 population. The year was happily not characterised by any special occurrence in the history of the prevalence of disease in the district, and the sanitary administration appears to have pursued a tolerably even course. Dr. Farr advocates the adoption of more stringent rules for preventing the spread of scarlet fever from public schools, and he suggests the observation of the following rules:—"1st. That parents shall not only give notice of the child's illness, but shall specify the *nature* of the illness causing it to absent itself from school. 2nd. A form of certificate should be supplied by the School Board for this purpose, to be filled in by the medical attendant, with the object of verifying the parent's statement. 3rd. A second form of medical certificate should also be supplied, producing evidence of the complete disinfection, not only of the bedding and wearing apparel, but of the body of the patient also, and fixing a date from the period of convalescence at which the child could be allowed to return. In the case of scarlet fever, I should recommend certainly not less than a month after all evidence of peeling had ceased. 4th. That all absentees during the prevalence of scarlet fever, suffering from sore-throat, or a *slight rash*, should not be readmitted to school without a certificate from a medical man showing that these had no connexion with scarlet fever."

Birkenhead.—Dr. Francis Vacher's report for 1879 comes to hand when we might reasonably begin to expect his report for 1880. It is a pity that these reports cannot be published earlier in the year, for, to have to study at the end of one year the events that occurred in the course of the preceding, when those events have been overlapped by later events, is, to say the least, somewhat tantalising. The health history of Birkenhead for 1879 was, fortunately for the place, uneventful, and Dr. Vacher's report contains little more than the bare record of occurrences. The borough, including the Union Hospital and Workhouse, had a birth-rate of 36·69, and death-rate of 19·23 per 1000 living. The infant death-rate compared favourably with the great centres of population, and with the whole country. Birkenhead, as other places, has been studying the methods adopted in Leeds for the destruction and carbonisation of house and town refuse. Dr. Vacher appears to be well satisfied with the results of the processes. But is he accurate when writing of the contents of "compound middens"—i.e., as we understand it, middens receiving *excrement* as well as ashes and dry house-refuse—being subjected to the destructive process?

Port of London.—Dr. Collingridge sends us his first report. It refers to the year ending June 30th, 1880, the first half of this period not having been reported upon in consequence of the illness and death of the late lamented Mr. Harry Leach. Dr. Collingridge, unwilling that a break should occur in the series of health-reports for the port, has, with the assistance of Mr. Johnson Smith, who acted as medical officer for the port from the death of Mr. Harry Leach to the date of election of Dr. Collingridge, contrived to fill up the necessary details for the missing half year, and thus maintained the continuity of the reports. Dr. Collingridge in the part of the report for which he is personally responsible has followed strictly the lines of reporting laid down by Mr. Harry Leach. He shows that not less than 7601 vessels, 3898 lying in the river and 3703 in docks, were inspected in the half-year ending June 30th, 1880, and the work of inspection may be expected to increase, or at least to become more arduous, when the extension of the Victoria Docks, now in progress, to a reach lower down the Thames is completed. Dr. Collingridge gives some curious particulars relating to the sewage pollution of the Thames which will demand his continued attention, and he shows that the Customs questioning of vessels entering the port by no means answers the requirements of the sanitary authority.

SMALL-POX IN THE EAST OF LONDON.

We elsewhere print a letter from a clergyman in the East of London which shows some of the defects of sanitary administration there in its relation to the present increase of small-pox. The following, relating to the defective administration of the vaccination law in one of the eastern districts of the metropolis, is from a letter addressed by Dr. Stevens, of the Local Government Board, to the Bethnal-green Guardians, Dr. Stevens having the general superintendence of vaccination matters at the Board since Dr. E. C. Seaton's death:—"In Bethnal-green, more than any other district, the increased prevalence of this preventable disease [small-pox] has been most marked. I find from the Registrar-General's Weekly Return for the four weeks ended last Saturday, that 56 deaths by small-pox had occurred in that month. Of these 56 deaths, 39 had occurred in the eastern districts, and of these 39 Bethnal-green contributed 22. From the same source of information I also learn that from Bethnal-green parish alone there were sent to the small-pox hospital no less than 27 cases of the disease in the ten days ended 21st ult. The great majority of these cases have been specifically certified as unvaccinated, while in one-fourth of their number a certified practitioner left the question of vaccination in doubt. Moreover, the returns for three of the weeks—for the other week the statistics are incomplete—show that more than half of the whole mortality occurred in persons under twenty years of age, and that of the fifteen unvaccinated persons who died in the week ended 27th November, twelve were of persons aged between one and twenty years. You will find here, in addition to the direct record of small-pox mortality—what might have been predicted—a very grave condition of unprotectedness. These conditions, I think, demand of the guardians of the parish of Bethnal-green exceptional activity, and I think some aid to the vaccination officer, for the purpose of making a complete visitation of infected districts, for the purpose of discovering all unvaccinated persons. I think it very unfortunate that, as I ascertained on the occasion of a visit I made to the parish on the 8th ult., the vaccination officer, instead of devoting all his time and energies to so increasing a spread of the malady he is specially appointed to guard against, was occupied a portion of the day in one of the parochial dispensaries." It appears that this vaccination officer is also a dispenser to the guardians, and, further, that he keeps a shop! It is calculated that his vocations as a dispenser occupy four hours daily (the shop being attended to by his wife). He is stated to be an excellent officer, but it is evident that the guardians simply require him to expend the balance of his time—his spare time, so to speak—in vaccination work. Need we wonder at the imperfection of vaccination in Bethnal-green, or the difficulty experienced in dealing with an advancing epidemic of small-pox? Truly the disease is there cultivated! Dr. Stevens, in the letter referred to, adverted to the need for a better understanding than appears to exist between the officers of the vaccination authority and the officers of the sanitary authority, and since then the Local Government Board has addressed a circular letter to the sanitary authorities urging them to instruct their officers to give all possible assistance to the officers of the vaccination authority in the discovery of small-pox.

THE HOMERTON SMALL-POX HOSPITAL.

Dr. Tripe's observations on extension of small-pox from the Homerton Small-pox Hospital to neighbouring houses were brought before a recent meeting of the Metropolitan Asylums Board. It was suggested that the Board should investigate the question; but a member took exception to this course on the ground that inquiry would or might imply that the Board did its duties inefficiently! Another member thought it was a subject for the Local Government Board if the Hackney vestry thought proper to move in the matter; then the subject *dropped!* Could anything more surely condemn the anomalous position in which the Board stands in a matter of this kind? We learn that the Local Government Board has taken up the subject, whether on the motion of Hackney vestry or not is not known, and that Dr. Bridges, the medical inspector of the Board for the metropolis, has been instructed to investigate it.

SUPERANNUATION.

The Local Government Board, in a circular letter calling attention to the diversity of practice by the different boards of guardians with respect to superannuation, expresses the opinion that the amount to be awarded to an officer who has served with efficiency for ten years or more, and for less than eleven years, should be an annual sum equal to ten-sixtieths of his salary and emoluments at the time of his ceasing to hold office, with an addition of one-sixtieth in respect of each additional year of service, until a maximum of forty-sixtieths, or two-thirds, be reached. In certain special cases a number of years, not exceeding ten, might be added to those of actual service.

Dr. Owen Coleman, the medical officer of health for Surbiton, in a report recently laid before his sanitary authority, writing of the recent cases of diphtheria which have occurred in that suburb due to infected milk, states that the inculpated dairy used water from two sources—one the town's supply, the other from a foul well on the premises. The town's water had been "laid on" because the well-water had been condemned as impure several months ago; but the well does not appear to have been then closed, and we infer that, as the foul water from it was "occasionally used," it was reserved for dairy purposes! The well, it may be added, is now closed. The cases to which we now especially refer appear to have occurred as an incident in a wider scattering of the disease due to more general causes.

The Lower Thames Sewerage Board are about to attempt to induce the Metropolitan Board of Works to give them an outlet for their sewage through the metropolitan main sewers south of the Thames.

At a late meeting of the Bridgwater guardians a letter was read from the Local Government Board with reference to the repeated prosecution of parents for the non-vaccination of children. The central board expressed the opinion that where there had been one prosecution the guardians might withhold directions to the vaccination officer if there should be good reason to suppose that the continuance of the proceedings would not ensure the vaccination of the child, or would prejudice the due observance of the law in the union generally. In this case surely the Vaccination Amendment Bill, which was introduced by Mr. Dodson last year, and withdrawn on account of the remonstrances of the profession, was superfluous.

A committee of the Halsted Guardians Authority have recommended the establishment of three cottage hospitals for the isolation of cases of infectious disease—one for the district containing the four parishes of Earl's Colne, Colne Engaine, White Colne, and Pebmarsh; another for the parishes of Castle Hedingham, Sible Hedingham, and Great Maplestead; a third for the parishes of Great Geldham, Little Geldham, Toppesfild, Tilbury, Stambourne, and Ridgwell. The recommendation has been referred to the Rural Sanitary Authority.

Dr. Wallace, the medical officer of health for Dundee, reports that for the four weeks ending the 18th Nov., and the five weeks ending 8th Dec., the death-rates of the town were respectively 22·8 and 28·6 per 1000 population. Three deaths from typhus took place in the first period, and 11 in the second period.

The Local Government Board has been impressing upon the Hackney Guardians the desirability that vaccination stations for populous urban or metropolitan districts should be of as public and permanent a character as possible, so that the people would become familiarised with them.

The Keighley Guardians have asked, or are about to ask, the Local Government Board for leave to suspend vaccination in the union during the winter months. It would be curious to know on what reasons this request is grounded.

The Metropolitan Asylums Board has refused to take or rent the new Poplar infectious disease hospital at Plaistow, regarding the terms asked by the Poplar District Board as unreasonable.

A complaint has been made to the Local Government Board by two justices of the peace that the fever hospital at Chesham has been prematurely closed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The continuance of unseasonably mild weather, combined with the effect of the Christmas holidays upon registration, caused a further decline in the English urban rate of registered mortality. In twenty of the largest English towns, estimated to contain in the middle of this year a population of nearly one-third of the entire population of England and Wales, 4214 births and 2668 deaths were registered last week. The births were 971, and the deaths 607, below the average weekly numbers during 1879. The deaths showed a further decline of 125 from recent weekly numbers; and the annual death-rate, which had steadily declined from 22·1 to 19·4 in the five preceding weeks, did not exceed 18·6 last week. The lowest death-rates in the twenty towns last week were 15·6 in Brighton, 16·3 in Portsmouth, 16·3 in Sheffield, 16·5 in Wolverhampton, and 16·5 in Birmingham. The rates in the other towns ranged upwards to 21·9 in Sunderland, 21·2 in Liverpool, 25·5 in Norwich, and 26·4 in Nottingham. Both the two last-mentioned towns showed excessive zymotic death-rates. During the first twelve weeks of the past quarter the death-rate in the twenty towns averaged only 21·4 per 1000, against 23·4 in the corresponding periods of the four years 1876–79.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 370 and 375 in the two preceding weeks, declined to 342 last week; they included 101 from scarlet fever, 80 from whooping-cough, 56 from measles, and 39 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2·4 per 1000 in the twenty towns; it ranged from 0·5 and 0·7 in Brighton and Birmingham, to 4·3 in Norwich, 4·5 in Sunderland, and 5·4 in Nottingham. The fatal cases of scarlet fever in the twenty towns, which had been 140 and 129 in the two previous weeks, further declined to 101 last week; the largest proportional fatality occurred in Norwich, Sunderland, and Nottingham. The fatality of whooping-cough showed an increase, and was largest in Sunderland, Leeds, and Nottingham. The highest death-rates from fever, principally enteric, were recorded in Nottingham, Wolverhampton, and Portsmouth. Of the 23 deaths from diphtheria in the twenty towns, no less than 16 were recorded in London. The deaths from small-pox in London, which had been 12 and 33 in the two preceding weeks, declined again to 15 last week; while no fatal case of this disease was returned in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 373 in the eight preceding weeks, further rose to 380 on Saturday last. The number of new cases of small-pox admitted to these hospitals, which had been 132 and 76 in the two previous weeks, further declined to 65 last week. The number of patients in the Highgate Small-pox Hospital were 28 on Saturday last, against 30 and 26 at the end of the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 295 and 307 in the two preceding weeks, declined again to 290 last week, and were no less than 273 below the corrected average number in the corresponding week of the last ten years; 175 resulted from bronchitis, and 71 from pneumonia. The annual death-rate from lung diseases last week was equal to 5·0 per 1000 in London, and 5·7 in Liverpool.

In the twenty towns last week 75 uncertified causes of death were registered, equal to 2·8 per cent. of the total deaths. The proportion of uncertified deaths was equal to 1·8 per cent. in London, whereas it averaged 3·7 per cent. in the nineteen provincial towns. No uncertified deaths were registered in Brighton, Portsmouth, Plymouth, or Newcastle-upon-Tyne; whereas their proportion was largest in Wolverhampton, Leicester, Bradford, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 20·8 per 1000, against 21·7 and 19·9 in the two preceding weeks; this rate exceeded by 2·2 per 1000 the average rate in the twenty large English towns. The rates in the eight Scotch towns last week ranged from 19·1 and 19·5 in Glasgow and Dundee, to 25·8 and 28·7 in Leith and Paisley. The deaths referred to the seven principal zymotic diseases in the eight towns, which had steadily declined from 112 to 80 in the four preceding weeks, rose again to 92 last week; they were equal to an annual rate of 3·7 per 1000, against 2·4, the average rate in the twenty English towns. In the eight Scotch towns the zymotic death-rate last week ranged from 2·7 in Edinburgh and Dundee, to 4·1 and 4·2 in Glasgow and Paisley. The fatal cases of scarlet fever, which had declined steadily from 53 to 17, in the six preceding weeks, rose again to 29 last week; they included 15 in Glasgow, 6 in Edinburgh, and 6 in Leith. The 21 deaths referred to diphtheria showed a further increase upon recent weekly numbers; 12 occurred in Glasgow, 3 in Edinburgh, and 2 both in Leith and Paisley. The 19 deaths from whooping-cough were also more numerous than in recent weeks, and included 9 in Glasgow, 4 in Dundee, and 3 in Edinburgh. Only 4 deaths were referred to fever in the eight towns, of which 3 occurred in Glasgow, and one in Aberdeen. The annual death-rate from acute lung diseases (bronchitis, pneumonia, and pleurisy) was equal to 5·0 per 1000 last week in the eight Scotch towns, against 3·6 in London; the highest death-rates from these diseases in the eight Scotch towns occurred last week in Dundee, Leith, and Perth.

HEALTH OF DUBLIN.

The death-rate in Dublin showed an increase again last week. The annual rate of mortality from all causes in the city, which had steadily decreased in the six preceding weeks from 39·6 to 25·9, rose again last week to 27·0. During the twelve weeks ending last Saturday the death-rate in the city averaged no less than 32·4 per 1000, against 20·7 in London, and 22·0 in Edinburgh. The 163 deaths in

Dublin last week showed an increase of 7 upon those returned in the previous week, and included 21, or 13 per cent., which were referred to the seven principal zymotic diseases, or 3 less than the number in the previous week; 8 resulted from fever (including typhus, enteric, and simple), 7 from scarlet fever, 2 from whooping-cough, 2 from diarrhœa, 1 from small-pox, 1 from measles, and not one from diphtheria. The annual death-rate from those zymotic diseases was equal to 3·5 per 1000 in Dublin last week, against 2·5 in London, and 2·7 in Edinburgh. The deaths referred to fever in Dublin, which had been 8 and 7 in the two previous weeks, rose again to 8 last week, and were equal to an annual death-rate more than five times as high as the average rate from the same cause in the twenty large English towns last week. The 7 deaths from scarlet fever in Dublin showed a decline of 4 from the number in the previous week; and the fatal cases of whooping-cough were also less numerous. The deaths both of infants and of elderly persons exceeded the numbers returned in recent weeks.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

NOTIFICATION OF INFECTIOUS DISEASES IN DUBLIN.

The Council of the Irish Medical Association have recently forwarded a circular to the profession in Dublin for the purpose of obtaining their opinion as to the best method of notification in infectious diseases. It is admitted that great benefits to the public may be expected from an efficient system of notification of infectious disease, but it has been urged that the duty should not be carried out by the medical attendant, as it would involve a breach of professional confidence, be irksome, and prejudicial to him in his private practice. There is little doubt, however, that if the measure is intended to be successfully carried out, the duty of notifying that infectious disease exists in any household must not be left to the householder. The Society of Metropolitan Officers of Health (Dublin), at a meeting held on the 8th of last December, passed a resolution to the effect that it was desirable that both the physician and the head of the family should notify. This plan Dr. Cameron approves, as he found that in November, 1880, out of a total number of 875 deaths, registered within the Dublin registration area, the cause of death was uncertified in 163 instances, and in 157 others there was no medical attendant. It is evident, therefore, that the compulsory notification of contagious diseases (measles, for example, which is easily recognised) by the head of the family is necessary, as in many cases there is evidently no medical attendant. Dr. Cameron in a recent report refers to this subject, and remarks that if the notification of cases of infectious disease were a duty devolving on the head of the family, he is quite sure that the middle and upper classes would not neglect it. But he is confident that great unwillingness to give such notice would be manifested by the majority of the denizens of the tenemental dwellings, though it is in the cases of such dwellings that a prompt notice would alone be really useful.

THE DRAINAGE OF THINLY-POPULATED DISTRICTS.

The medical officer of health for Honiton, Dr. Stephenson, has published some thoughtful remarks on the drainage of suburban and thinly-populated districts by means of small pipes and flushing tanks. He thinks that the flush-tank may be applied to the *complete* drainage of the house, and that, combined with a small-pipe system of drainage, such as was used at Memphis, it offers a solution (particularly on the score of expense) of much of the difficulty of dealing with questions of drainage in thinly-populated districts. We shall be glad to learn that his suggestions have been submitted to the test of experience.

A case has just been heard in the Chancery Division of the High Court of Justice (May *v.* Verity) which is important to householders. The defendant agreed to take an assignment of the lease of a house, and after he had possession he discovered not only that the drainage was in a bad state, but that the drains of other houses ran beneath the house he had agreed to take. Thereupon he declined to carry out his agreement, and proceedings were taken against him to compel specific performance. Among other points urged by the defendant against this, the unwholesome state of the building was advanced, and testified to by Professor Corfield and the sanitary inspector for Paddington, Mr. Clifford; but this would probably have gone for nothing in the mind of the court, and had it not been that the lease specified that the neighbouring houses had a use of the drain beneath the house for "water," and did not specify its use for "sewage," which nevertheless was poured into it, the defendant would probably have been compelled to carry out his agreement.

Yellow fever is reported as being prevalent in St. Louis, Senegal. A quarantine of four days has been ordered for vessels arriving in the Gambier from Goree.

THE SERVICES.

THE WAR AT THE CAPE.

The following list comprises the medical officers at present employed in the Cape command:—Deputy Surgeon-General J. Holloway, C.B., Principal Medical Officer; Surgeon-Majors Wm. Skeen, P. W. Stafford, Wm. Elgee, T. Babington, J. N. Stock, H. Comerford, W. A. Jenings, R. C. Parkinson, J. Fraser, J. H. Asher, Wm. Geogheghan, A. L. Brown, C. B. Jennings, and A. H. Stokes; Surgeons G. Ryan, W. E. Saunders, G. D. N. Leake, J. W. O. Martin, E. C. R. Ward, J. Ring, J. Magann, A. J. Landon, J. L. Ritchie, K. Wallis, O. E. P. Lloyd, A. Harding, J. Falvey, and J. F. Dowman. A considerable augmentation to the above staff will be despatched with the reinforcements ordered out to Natal as soon as transport can be provided. The War Office authorities are also sending out large quantities of medical and surgical stores, ambulances, medical comforts, &c., for the use of the hospitals in the Transvaal.

In a telegram from the General Officer commanding at Natal to the Secretary of State for War, dated Pietermaritzburg, Dec. 28th, occurs the following passage:—"Dr. Ward, only unwounded officer, remains with wounded. Ambulances and medical attendance sent out from Pretoria."

Surgeon Wolseley embarked for China on the 29th ult., in medical charge of a draft of 500 men on board the transport *Scotland*.

Brigade-Surgeon Alfred M. Tippetts has been appointed to the charge of the Station Hospital, York, on return from Afghanistan.

Surgeon J. F. Roberts, Bengal Medical Service, has been permitted by the Secretary of State for India to resign his commission.

"Audi alteram partem."

RETARDED SIGNS IN PNEUMONIA.

To the Editor of THE LANCET.

SIR,—In a valuable paper, read at the Clinical Society by Mr. Tyson of Folkestone, and reported in THE LANCET, Dec. 18th, 1880, it is stated that a late development of the physical signs of pneumonia is an occurrence not generally recognised among the phenomena of that disease. I would venture to assert, on the contrary, that while it may be quite true that the significance of the fact has been little considered, yet that the fact itself has been known from the earliest times, and, indeed, long before the real nature of pneumonia was understood as an affection of limited duration, tending to spontaneous recovery.

For proof of this assertion I might go back more than a hundred years, to the middle of the last century, and Dr. Huxham, who looked upon the local inflammation of "pneumonic fever" as a subordinate part of it. It is more to the point, however, to come to the time when, with the first employment of auscultation, physical signs were most implicitly and entirely trusted both to discover pneumonia and to trace its progress. More than fifty years ago, when physical signs went for everything, Andral admitted, very unwillingly we may be sure, that there were instances in which the local inflammation appeared to be no more than the consequence of the fever. He reports at length a case in which six days at least intervened between the first onset of fever and the earliest physical signs. "All the organs," he writes, "seemed to be simultaneously the seat of a strong excitement, without there being in any part real inflammation. No organ was really inflamed, but all seemed on the verge of it."

As regards the explanation put forward at this meeting that in such cases the inflammation is really present all the while, but out of the ear's reach, there are, as I think, several reasons against accepting it. To mention but one: how is it that the physical signs of pneumonia which are not really new but, according to the hypothesis, first come within hearing on the fifth or sixth day, should yet present all the signs of a new pneumonia undergoing its transitions and reaching its time of crisis accordingly?

My present object, however, is not to discuss a controverted point, but to maintain that the fact of pneumonic pyrexia preceding its local signs, far from being a new observation, is amongst the oldest and most familiar. The real question is, whether such is not the rule of the disease; so that if we happened to be by at the very time when, with such remarkable suddenness, the first rigor of pneumonia interrupts the course of health, we should be unable in the majority of cases, although perfectly assured from many signs of the nature of the seizure, to detect for some hours the first physical indications of inflamed lung.

Yours obediently,
OCTAVIUS STURGES.
Wimpole-street, Dec. 20th, 1880.

"LISTERIAN" OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—Your suggestion that the Royal Medico-Chirurgical Society should appoint a committee to investigate this subject is a good one, though I greatly fear they could not come to any very definite conclusions, unless they were prepared to watch a series of cases in the practice of the same operators, half of which should be done without the Listerian details, and half with them. In such an investigation the method of recovery alone could give any trustworthy indication of the value of the methods employed. The mere death-rate is of scarcely any value at all, for with one exception the deaths I have had since I gave up the clamp have arisen from causes over which neither the use nor the absence of the Listerian details could have exercised the slightest influence. The exception is that of a patient poisoned by the use of thymol.

I have tried a long and careful experiment, the results of which have been most satisfactory, and they are briefly, that as the quantity of carbolic acid used for the operation is diminished so does the patient recover more easily, with less fever, distension, and sickness.

This experiment has been tried with the ligature exclusively, and I am now on the point of repeating it with the cautery, but I have already revived the high temperatures, distension, and consequent anxiety, which for more than a year I had been quite free from.

I cannot reconcile the statements of my friends, who tell me such marvellous things about their experience of Listerism in general surgery, with my own experience in abdominal surgery, and as my practice is entirely limited to this special field, and as I have no grounds for doubting the statements of my friends, I can only feel that an explanation will be found in the peculiarities of the peritoneum. This, I think, has been fully sustained by Dr. Bantock's paper.

I am, Sir, yours, &c.,
LAWSON TAIT.

OVARIAN DYSMENORRHŒA, WITH RETROFLEXION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—I am indebted to Dr. Wynn Williams for his criticisms on the case under my care, published in your "Mirror" of Dec. 4th. Will you permit me to say in reply—

1. I regard it as certain that flexion of the uterus, unaccompanied by other morbid changes, produces no symptoms. But, as distinguished gynæcologists have put forward reasons for thinking that bending of the womb may cause congestion of that organ and ovaritis, I judged it proper to endeavour to straighten the uterus in the case reported. It was demonstrated, by the result of treatment, that the symptoms did not depend upon the shape of the uterus, and this, the main point of the case, and the reason of its publication, is not affected by Dr. Williams's criticisms.

2. I did not deplete the uterus, because menstruation was already too frequent and profuse. If intra-uterine stems are only safe when morbid conditions of the uterus have been first removed—in other words, when the uterus is healthy—I fail to see why they are used.

3. The explanation Dr. Wynn Williams gives as to why the patient was not sterile I admit to be a possible one, but the proof is wanting. Dr. Williams will confer a favour upon the profession if he will tell us how many cases of sterility he has treated with his stem, how long each of them had been sterile, and how many of them subsequently became pregnant.

I am, Sir, yours, &c.,
G. ERNEST HERMAN.
West-street, Finsbury-circus, Dec. 27th, 1880.

"A CHEMICAL LUNG."

To the Editor of THE LANCET.

SIR,—In August last you mentioned with approbation my scheme for a "chemical lung" designed to purify the air of the tunnels of the underground railway, and deemed it worthy of a trial. After long delay the directors lately granted me an interview to explain my scheme in detail. The objections urged, and which they considered fatal to carrying out the scheme, were, first, that the traction powers of their engines were already taxed to the utmost, and that therefore another carriage added would stop the train. To this, my reply that on boat-race days, for example, the overcrowding of the carriages did not arrest their progress, elicited no satisfactory answer. Secondly, I was asked by the practical chemist of the board what I meant to do with the carbonic acid evolved from the hundred tons of coal daily consumed; but my reply that I had only to deal with a limited portion of that gas—viz., so much as was contained in the tunnels from King's Cross to Edgware-road—seemed to excite that gentleman's pity for my want of chemical knowledge. The result of the interview was that the directors declined attempting to purify the tunnel atmosphere by the means proposed. Yours truly,

RICHARD NEALE, M.D. Lond.
Boundary-road, South Hampstead, Dec. 17th, 1880.

PARIS.

(*From our own Correspondent.*)

ANOTHER patient suffering from locomotor ataxia has been submitted by MM. Debove and Gillette to the operation of nerve-stretching, and with a most satisfactory result. The following account of the case is taken from the *Progrès Médical*:—"On the 16th of December M. Debove, with the assistance of M. Gillette, made another trial upon an ataxic patient, who, encouraged by the relief of his comrade, himself desired the operation. In this case there were incessant darting pains, sometimes paroxysmal, in the upper extremities. The median and radial nerves on the right side were stretched. The operation, very simple in itself, was as follows. An incision, about seven centimetres in length, was made along the course of the bundle of nerves which was thus exposed; a director was then passed under the nerves in question, with its convex side towards them, and being held by its extremities, a sufficient traction was made to raise them five or six centimetres. It may be observed that such a strain can be borne without any fear of rupture. Experiments made upon the dead subject have shown that a force of forty-two kilogrammes is necessary to tear the radial, and this is considerably above that which was exerted on this occasion. A few sutures in the skin and a carbolic-acid dressing completed the operation. Healing took place by first intention. In this case, as in the former one (see THE LANCET, Dec. 18th, 1880), there was a considerable decrease in the intensity of the pains in the right, and a complete cessation of them in the left upper extremity, as well as in the lower limbs. The plantar anæsthesia is less on the left side, motor incoördination is decreased, and it is now possible for the patient to walk without support. Regular sleep has returned and morphia is no longer required, as "the pains are as nothing to what they were before." A definite judgment as to the value of this treatment is not yet possible. Although the immediate result is most surprisingly satisfactory, it is difficult to say what will be the ultimate effect upon the spinal cord, and the merits of the operation can only be weighed by more extended experience. There is no doubt, however, that this experience will soon be forthcoming, for locomotor ataxia is one of the commonest of the medullary affections admitted into the hospitals of Paris, and Dr. Debove's success is sure to lead others to follow in this path.

It seems likely that the Hôpital St. Antoine will shortly undergo considerable improvements. A few years since a sum of £40,000 was left to the town of Paris by a wealthy citizen for the construction and maintenance of a hospital, which, according to the terms of the will, was to bear the founder's name, and to be mainly devoted to the relief of poor and sick women. No steps having been taken to carry out the testator's wishes, the other heirs lately requested the "administration" to give them effect, and in consequence a *projet* has been presented to the competent authorities by the prefect. It is proposed to enlarge the Hôpital St. Antoine, and to construct a new building in its vicinity, which shall be called after its founder, the "Pavillon Moïana," and contain eighty beds.

A scheme for the enlargement of the Ecole Pratique has come before the Municipal Council, and if put into execution Paris will be able to rival even Vienna in this respect. All the buildings which are now situated between the new Hôpital des Cliniques and the Boulvard St. Michel in one direction, and the rues de l'Ecole de Médecine, Monsieur-le-Prince, and Racine in the other direction, would be removed, and the new school rebuilt on this site. It would contain lecture-theatres for the *professeurs libres*, who correspond to the German *privat-docenten*, debating-rooms for different learned societies, and a number of laboratories and museums.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Dec. 23rd:—

Daniell, Charles Henry, Derby.
Gleeson, John Gerald, Cromwell-street, Belgravia.
Long, Richard Patrick, Essex House, Bow.
Verdon, Michael John, Craven-street, Charing-cross.
Wood, Edward Archer, Marlborough.
Wordley, Alfred William, Green-street, Suffolk-street.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Frank Allwork, Westminster Hospital; John Fredk. Williams, John Lyndsay Rodwell, and William Edgar Sicard, Charing-cross Hospital; Hy. Nelson Holberton, St. Thomas's Hospital; Walter A. W. Potts, St. Mary's Hospital; Wilfred Murch, St. Bartholomew's Hospital; Francis Hy. Vivian Voss, London Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners held on the 10th ult. and following days the undermentioned were admitted Licentiates of the College:—

Herbert Joseph Bermingham, Francis George Bonynge, Shepland M'Cormick Boyd, Francis Foster Brady, Louis John Patrick Carroll, Arthur Gerard Chance, Francis Philip Colgan, Patrick Arthur Daly, Valentine Plunkett Dillon, Charles James Douglas, Thomas James Dowse, Frederick William Exham, Michael Edward Fitzgerald, Thomas M'Craith Foley, William Gern, Michael Hayes, Patrick Hoey, William Gardiner Jacob, William Wall Jacobs, Sidney Geo. Jennings, Denis Patrick Kenna, John Keenan, Arthur William M'Math, Henry Strickland M'Gill, Francis John Mulock, Daniel Moon, Arthur Hill Murray, Reginald Lawson Morley, John Patrick Nicolls, Daniel Butler Reardon, Wm. Smyth, John Joseph Stack, Henry James Wyatt.

UNIVERSITY OF DUBLIN.—The undermentioned gentleman has obtained the diploma in State Medicine of the University:—

Polden, Robert J., M.B., B.Ch.

A DEATH from trichinosis, in a butcher who was in the habit of eating raw pork, is reported as having occurred at Bellevue Hospital, New York.

INTERNATIONAL EXHIBITION OF HYGIENE.—O Wednesday, Dec. 29th, at a meeting of the Committee the Parkes Museum of Hygiene, Mr. George Godwin, F.R.S in the chair, a proposal was made to hold an Internationa Exhibition in 1881. After a long discussion, in which D G. V. Poore, Professor Corfield, Mr. E. C. Robins, M Rogers Field, Dr. Gowers, and Mr. Mark H. Judge too part, the following resolution was unanimously passed:— "That Her Majesty's Commissioners of 1851 having expressed to the Committee of the Parkes Museum of Hygien their willingness to provide space at South Kensington fo an exhibition of Sanitary Appliances, and other industrie connected with Medicine, on the occasion of the International Medical Congress in 1881, it is desirable that th Committee should organise such an exhibition, provide that a sufficient guarantee fund be obtained." Those desirous of assisting the Committee in the work they hav thus entered upon, are requested to send their names to th treasurer of the Museum, Professor Berkeley Hill.

ASSOCIATION OF SURGEONS PRACTISING DENTA SURGERY.—The following is a list of the names of gentleme proposed by the Council as officers of the Association for the year 1881:—President: Mr. T. Edgelow. Vice-Presidents Messrs. T. A. Baker, Samuel Cartwright, W. A. N. Cattlin, Francis B. Imlach, S. T. A. Salter, F.R.S., and John Smith, M.D., F.R.S. Ed. Treasurer: Mr. S. H. Cartwright. Hon. Sec.: Mr. J. Hamilton Craigie. Council: Messrs. E. Bartlett, J. Fairbank, F. Fox, C. Gaine (Bath), W. A. Hunt (Yeovil), W. D. Napier, W. G. Ranger, and Augustus Winterbottom. The annual meeting for the election o officers &c. will be held on Wednesday, Jan. 25th, at 8 P.M., when an address will be given by Mr. W. A. N. Cattlin, F.R.C.S., "On the Imperfections of the Dentists Act, with suggestions as to the alterations required to protect the interests of Qualified Surgeons."

VACCINATION GRANTS.—The following gentlemen have received the Government grant for efficient vaccination in their respective districts:—Dr. Geo. R. Barnes of Ewell, Surrey (fourth time). Mr. J. R. Clouting, Thetford Union (second time). Dr. Sealy of Weybridge (fourth time). Mr. R. Istance, Risca district (fourth time). Dr. Mayou of Monmouth (fifth time). Also Mr. Frederick Morgan of Wellington, Somerset.

DR. F. OGSTON, sen., of Aberdeen, who has held the office of police surgeon for nearly half a century, has placed his resignation of the post, together with that of medical officer of health, in the hands of the Town Council of Aberdeen, undertaking to do the duties of both offices until his successor shall be appointed.

THE University of Durham Medical Society held a *soirée* in the Wood Memorial Hall on Dec. 21st. The meeting was a most enjoyable one, being enlivened by good music, and furnished with numerous specimens of microscopical research.

DR. THOMAS WOOD, of Cincinnati, has died from blood-poisoning caused by attending with chapped hands to the wounded in the recent railway accident on the Cincinnati, Hamilton, and Dayton line.

A MEMBER of the Newcastle Board of Guardians was last week fined 5*s.* for neglecting to have his child vaccinated. The defendant declined to pay the fine.

MR. W. K. WAIT has contributed £500 to the building fund of University College, Bristol, in addition to £250 previously given by him.

UNIVERSITY COLLEGE HOSPITAL.—Prince Leopold has consented to preside at the annual festival dinner in aid of the funds of this charity on May 20th, at Willis's rooms.

MOST of the Dublin hospitals and charitable institutions provided a special dinner for their inmates on Christmas Day, and gifts were largely distributed.

DR. GRIMSHAW, Registrar-General for Ireland, has been appointed one of the Commissioners for taking the Census in Ireland in 1881.

MR. R. E. GAGE, medical officer of the Workhouse, Paddington, has received a gratuity of £50 in consideration of extra services rendered by him during the past year.

DR. PETER EADE has been elected Sheriff of Norwich for the year 1880-81.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

BAILEY, H. B., M.R.C.S.E., L.S.A.L., has been appointed Surgeon to the Brownlow Lodge (Great Gonerby) of the Independent Order of United Brothers.

BURROWS, W. S., L.D.S., R.C.S., has been appointed Dental Surgeon to the North-West London Hospital.

CEELY, J. H., F.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Workhouse and the Aylesbury District of the Aylesbury Union, vice R. Ceely, deceased.

DAVISON, R. S., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the Castleward Rural Sanitary District, Northumberland, vice Marr, whose appointment has expired.

DONOVAN, R. E., M.D., has been appointed Medical Officer to the Galbally Dispensary, Limerick, vice O'Connor, deceased.

GREENSILL, J. N., M.R.C.S.E., has been appointed Honorary Assistant-Surgeon to the Darlington Hospital, vice Lowes, resigned.

HINE, J. E., M.B., has been appointed Junior Resident Medical Officer to the Radcliffe Infirmary, Oxford, vice A. R. Oxley, resigned.

HORSFALL, H., M.D., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Masham Urban Sanitary District.

KAYE, J., M.B., C.M., has been appointed House-Surgeon to the Huntingdon County Hospital.

KIDD, P., M.B., has been appointed Casualty Physician to St. Bartholomew's Hospital, vice Harris, resigned.

MACARTNEY, T. L., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Surgeon to the Roman Gravels, and Wotherton Mines.

MASSIAH, B. J., M.D., M.R.C.S.E., has been appointed Physician to the General Hospital and Dispensary for Sick Children, Pendlebury, and Gartside-street, Manchester, vice Borchardt, resigned.

MORGAN, J., F.R.C.S.E., L.R.C.P.L., L.S.A.L., has been appointed Medical Officer of Health for the Langport Rural Sanitary District, Somersetshire, vice Tims, resigned.

MURRELL, W., M.D., M.R.C.P., has been appointed Extra Physician to the North-West London Hospital.

NETTLESHIP, E., F.R.C.S.E., has been appointed Ophthalmic Surgeon to the Hospital for Sick Children, Great Ormond-street.

SCHREIBER, Dr. A., of Augsburg, has been appointed one of the Resident Medical Officers to the German Hospital, Dalston, vice Dr. G. Ludwig, M.R.C.P., resigned.

SHEILD, A. M., L.R.C.P., M.R.C.S.E., late House-Physician to St. George's Hospital, has been appointed House-Surgeon to Addenbrooke's Hospital, Cambridge, vice Ground, resigned.

STEDMAN, A., M.R.C.S.E., L.S.A.L., L.M., has been appointed Medical Officer to St. John's Foundation School, Leatherhead.

VACHELL, E. S., M.R.C.S.E., has been appointed Senior Resident Medical Officer to the Radcliffe Infirmary.

YOUNG, Mr. W. C., has been appointed Public Analyst for the Whitechapel District.

Births, Marriages, and Deaths.

BIRTHS.

KENDALL.—On the 28th ult., the wife of Surgeon-General Henry Kendall, M.D., Poor-law Medical Officer, Chatham District, of a son, who survived his birth only a few minutes.

PALEY.—At East London, South Africa, the wife of J. Hewitt Paley, M.R.C.S.E. &c., of a daughter.

ROWORTH.—On the 26th ult., at Grays, Essex, the wife of Alfred T. Roworth, M.R.C.S.E., of a son.

MARRIAGES.

GODFRAY—BERTRAM.—On the 9th ult., at Grouville Parish Church, by the Rev. Isaac W. Tapper, M.A., Alfred Charles Godfray, M.B., L.R.C.P., of La Motte, St. Helier's, to Edith Elsie, daughter of Mr. H. C. Bertram, of Grouville, Jersey.

HUTTON—DAVIES.—On the 28th ult., at Tyndale Chapel, White-ladies-road, Bristol, Mamie Hutton, second daughter of the late William Hutton, of Glasgow, to D. Arthur Davies, M.B., of Swansea.

DEATHS.

FRANKLIN.—On the 26th ult., suddenly, while presiding at a public examination of the Manchester Jews School, Isaac A. Franklin, M.R.C.S.E., of Park Villa, Fallowfield, near Manchester, aged 68.

GOODMAN.—On the 23rd ult., at his residence, Eastbourne House, Gloucester-road, Birkdale, Southport, Charles Rowland Goodman, M.D., late of Manchester, aged 43.

KER.—On the 23rd ult., at Hadley House, Cheltenham, Isabella, wife of C. B. Ker, M.D., aged 47.

PARKINSON.—On the 23rd ult., at Tiptree Rectory, Essex, Alice Frances, wife of Mr. Edmund Wollaston Parkinson, M.R.C.S.E., L.R.C.P.Ed., of Melbourn, Cambs.

TOULMIN.—On the 22nd ult., suddenly, Abraham Toulmin, M.D., of Russell-road, Kensington, W. (for 19 years Surgeon to the Tower Hamlets Dispensary), in his 86th year.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

OPIUM-TAKING IN AMERICA.

DR. EARLE, physician of the Washingtonian Home, Chicago, has published the result of some observations made by him on the subject of opium-taking. During the last five years, he believes, the practice has increased, fostered, probably, by the ease with which the drug seems to be procurable. Thus fifty druggists of whom inquiries were made acknowledged to having 235 customers amongst them. Of these the great majority (169) were females; the age of the larger number of the victims of this pernicious habit was between thirty and forty years, and they were mostly of the middle class. Various reasons are given for taking the drug—e.g., its stimulative and happy effect, previous addiction to drink, unhappy marriage, rheumatism, neuralgia, "female complaints," previous sickness, wounds received during the war, loss of property, and so on. But the great majority confess it was prescribed during some disease in which pain was a prominent symptom. Women generally use morphia, men of the lower class gum opium, a few of both sexes use the tincture, while occasionally one is found taking large doses of paregoric. A widow, aged fifty, buys of one druggist half a gallon every week. A large number of ladies take one-third to one grain of morphia daily. The great bulk of the drug consumed is by the mouth. Some take a dose two or three times a day, while some of the oldest opium-eaters prefer a large dose at intervals of from one to three days.

A Constant Subscriber.—The second question is an arithmetical one, and not calling for any special answer from us. As to the duties of a consulting physician, strictly speaking they consist in seeing only medical cases, and those only in consultation with the ordinary attendant of the patient. But, practically, we consider this condition would be observed by Dr. A. seeing no patient at his own house at less than a fee of one guinea, and, of course, observing the conditions of area stated in the contract.

THE LATE MR. JAMES CASKIE, OF LARGS.

WE regret that the notice of Mr. Caskie's death did not reach us sooner. A mason of fifty years' standing, and long holder of various public medical offices, cannot die even at a ripe old age without deserving the tributes which were freely bestowed on him by his brother masons, but also by the various public bodies, whose complimentary resolutions well testify their regard. One of the most efficient compliments a public body can pay to an old and meritorious servant is to give his appointments to his son, and we are glad to notice that the respect of the Parochial Board of Largs has taken this form.

"HOSPITAL ADMINISTRATION IN INDIA."

To the Editor of THE LANCET.

SIR,—I trust you will allow me, as a friend of Dr. D. B. Smith, who is not at liberty to speak for himself while in the service of Government, to say a few words in reference to an article which appeared in your issue of the 20th November; and, in the first place, I would remark that it appears to me, as to others, that but for the observations which you made on the 21st August, pointing out that in fairness to Dr. Smith his reply to the Government of the Bengal Resolution should be published, it would most probably not yet have been so, and, as it is, the concession has been made in a grudging, ungracious manner, and Dr. Smith's letter has been sent to the newspapers only, but has not been printed in his official gazette in which the Resolution to which it was a reply appeared. You call the letter long and wordy, and consider that it would have been better for Dr. Smith if it had not been published. It was as a matter of necessity long, seeing that it had to answer so many charges, and to indicate so many mistakes regarding himself, which appeared in the report of the committee that inquired into hospital management in Calcutta. With your permission I shall call attention to one or two points which I think will show that Dr. Smith has done himself good by obtaining the publication of his reply. Take the case of the diets of the Medical College Hospital to which you allude. In the year 1870, when food was much cheaper in Calcutta than it is now, a committee, of which Dr. Payne, the present surgeon-general, was a member, recommended that the rates should be raised from 1*s.* 1½*d.* to 1*s.* 6*d.* for each European, and from 6*d.* to 9*d.* for each native diet. This committee of 1870 stated that the rate of 6*d.* for natives was too low to secure the stimulants and extras required for the numerous cases admitted in the last stages of exhaustion, and that, though the European rate had not been exceeded, it was, in their opinion, not sufficient to procure meat and milk good enough for the sick. They further reported that the average rate for Europeans of 1*s.* 6*d.* a day has long been "an average rate of charge in the European Lunatic Asylum, where all are on full diet, but none require the costly stimulants and extras that are largely used in the Medical College Hospital." But Sir A. Eden's Committee, of which Dr. Payne, who is also superintendent of the European Lunatic Asylum, was a member, recommended two years ago that the rates for Europeans should again be reduced to 1*s.* a day, and 5½*d.* for each native.

Dr. Smith in his letter further shows that, according to the analysis of Professor C. H. Wood, the milk supplied under the contract rates in the early part of 1879 consisted of milk 56 and water 44 parts. In estimating the sufficiency of the present rates, it is very necessary to take into consideration that the patients to a large extent obtain food for themselves by purchase, or by having it sent in by their friends. A short time ago it was ascertained that on an average thirty patients daily, or upwards of 10,000 a year, thus supplemented the hospital allowance. I am aware that the practice is said to be "contrary to orders," but if there are such orders they are never enforced. From the report of Sir A. Eden's Committee the public were led to infer that patients in the Medical College Hospital were freely regaled on champagne, jellies, fruit, and cigars! such entries having been detected among the articles of extra diet. Dr. Smith, however, has shown that the expenditure on account of champagne from 1871 to 1872 was £26, or £3 5*s.* a year, while the largest expenditure was incurred by a single surgeon in one of the years, and amounted to £22 7*s.* 6*d.* He has also shown that the cost of cigars for the three years 1872, 1873, and 1876, when he was in charge, was 1*s.* 7½*d.*, the cigars having been allowed to asthmatic patients who found relief by smoking. The expenditure on account of jellies during the above three years was £22 5*s.* 6*d.*, and on account of pomegranates for native patients £7 8*s.* 3*d.* In conclusion, let me ask your attention to another part of Dr. Smith's reply. The Government of Bengal, in reviewing the reports of the hospitals of Calcutta for the year 1877, mentions Dr. Smith, along with other medical officers, as having the "satisfaction of knowing that their labours to render the hospitals under their charge worthy of the confidence of the public have been eminently successful." Yet, in face of this resolution, a committee subsequently appointed has laboured to create an impression that the management of the Medical College Hospital, as well as others, was anything but "eminently successful."

The Government of Bengal has very recently been forced to admit that an appalling mortality in the gaols of that province for the year 1879, amounting to 94·8 per mille, was chiefly due to insufficient diet. I happen to know something of the statistics of the hospitals of Calcutta published as well as unpublished for the year 1879, and am rather curious to compare results with those of the current year. There has now been time to test the new rates, but so long as so many patients who can manage it are allowed to supplement their hospital food it must be impossible to arrive at a definite conclusion. My own idea is that economy is looked on as more important than the interests of the sick.

Yours faithfully,

JAS. IRVING, M.D.,
Late Surgeon-General to the Bengal Government.

Edinburgh, Dec. 7th, 1880.

⁂ We publish Dr. Irving's letter solely on the plea advanced in the first paragraph, that Dr. D. B. Smith "is not at liberty to speak for himself while in the service of Government." But we feel bound to say that it does not in the slightest degree modify the opinions expressed in our leader of the 20th November, which were formed after a very careful perusal of all the published documents, including Dr Smith's own letter.—ED. L.

A VETERAN HUNTER.

DR. GRESHAM, of Louisville, is (says an American contemporary) ninety-seven years of age, and has just started for the mountains on his "last hunt." He is the only living fort-born native of Kentucky. When he came into the world his parents were dodging arrows and tomahawks, and his youth was spent with the rifle in his hand. He says he cannot die in peace until he shall once more have eaten venison of his own killing and cooking.

ERYTHEMA.

To the Editor of THE LANCET.

SIR,—The remarkable case which you reported as having been lately brought before the Clinical Society by Dr. T. C. Fox had been for a long time under my care, as was then stated by Dr. Carrington. I also saw the patient's sister, and agree with Dr. Fox that both are suffering from the same affection of the skin; but I cannot think that we gain anything by naming it "persistent gyrate erythema." If by the term erythema we mean any common superficial inflammation of the skin which does not go beyond the stage of papules, it will include the rashes of measles, scarlatina, and syphilis, the early stage of eczema, and the symptomatic eruptions caused by shell fish, and other gastric irritants. If to this anatomical definition we add the characters usually ascribed to "erythemata" of preference for the upper extremities, acute course, and "accidental" origin, the term is still less applicable to the case in question. Poril has lasted nearly a lifetime, it occurs in the members of the same family, and it is characterised not by the branny desquamation which follows an erythematous inflammation, but by the presence of slowly-formed, persistent, and adherent scales.

I exhibited the patient at the Hunterian Society in 1878 to several experienced dermatologists, but none of us could recognise it as coming fairly under any recognised term. I satisfied myself, as Dr. Fox has done, that the disease is neither parasitic nor syphilitic, and entered it in my notebook as an anomalous form of chronic serpiginous dermatitis.

Is it not better to be content with describing such cases as we meet with them, and recording them when we can collect two or three of the same kind, rather than to add to the already overgrown crop of dermatological nomenclature by inventing a new name for each new comer?

In this case the question seems to me to lie between regarding the affection as a very mild and irregular form of lupus, or a very chronic and aberrant case of psoriasis. The want of proof of implication of the sebaceous glands and the probability from the absence of scars that the dermatitis did not go deeper than the papillary layer of the skin, appear to negative the former supposition. On the other hand, the early appearance of the affection, its chronic course with frequent exacerbations, the distribution of the eruption chiefly, though not at all exclusively, on the extremities and on the extensor surfaces, its dry and scaly form, its serpiginous progress and consequent gyrate pattern, all seem to point to a relationship with psoriasis. When to this we add that the disease appears in a brother and sister, and that my patient improved decidedly under full doses of arsenic, many other modes of treatment having produced no change, the evidence is certainly strengthened, but I do not pretend that it is conclusive.

I had drawings taken at the time, which I should be happy to show Dr. Fox, and a fuller account of both cases when under my care will appear in the forthcoming volume of the Guy's Hospital Reports.

I am, Sir, yours, &c.,
Harley-street, Dec. 3rd, 1880. P. H. PYE-SMITH.

NIGHT MEDICAL SERVICE IN NEW YORK.

BETWEEN the 5th of September, when the night medical service was put into operation in New York, and the 30th of the month, twenty-five visits were (says an American contemporary) made by fifteen physicians of the service, and of the patients visited, three paid fees. The majority of these were cases of sudden illness or emergencies occurring in the night-time among the poor, and there appears to have been no attempt on the part of anyone to take undue advantage of the charity.

T. Johnson.—We do not indicate particular physicians or surgeons.

Hygiene should write to the registrar of the university for a prospectus of the course of study.

Senex has not enclosed his card.

GLACIALINE.

To the Editor of THE LANCET.

SIR,—A food preservative termed "glacialine" has recently been introduced to public notice, and has already acquired a deservedly wide reputation. It possesses the remarkable property of preventing putrefaction and obviating fermentative change in liquid and solid foods. These qualities, together with its perfect harmlessness when taken into the stomach, or when topically applied to the skin or mucous membranes, induced us to think that in suitable cases it might be used as a medical agent. Having had occasion within the last few months to treat a large number of cases of diarrhœa, especially in children, and finding some of these cases very intractable, we determined to try the effect of glacialine, and the results have been highly satisfactory, and have far exceeded our expectations.

It has been demonstrated that sour milk irritates the whole alimentary canal; it will therefore be easily understood that such milk taken into the stomach of a delicate child will produce diarrhœa, and often cause death. Now, we argued, since glacialine prevents milk from turning sour, it will prevent diarrhœa. But we had two points definitely to solve. Firstly, whether glacialine possessed any physiological action on the system of children which would prove deleterious. Secondly, whether it would prevent or change the normal action of the gastric juice on the milk in a child's stomach. In order to settle these points we carefully watched its action in a large number of cases, and found that so far from being injurious in any way, the health of each child was considerably improved by the addition of glacialine to its food. And we have used considerably more of this substance than is necessary to keep the food sweet. With regard to the action of the gastric juice, we find it in no way interfered with. Our experience has been that although glacialine prevents the milk from decomposing when exposed to the air, the normal process of digestion in the stomach goes on as well with as without glacialine. We therefore believe an enormous amount of sickness and death among children would be prevented by simply using a small quantity of this perfectly harmless glacialine in their food.

Where diarrhœa actually exists, either from sour milk or unripe fruit, we recommend two to four grains of the glacialine powder with a little sugar of milk, three or four times daily, before food, or, with greater efficacy, dissolved in the child's milk in the proportion of three or four grains to the half pint. In this, as in other varieties of diarrhœa, it is unwise to attempt to check the discharge until all the materials in the stomach and bowels of an irritating character are got rid of. It is, therefore, a good practice to begin the treatment by giving a dose of olive or castor-oil.

An ointment made by thoroughly mixing a drachm of glacialine with an ounce of unguentum cetacei forms an excellent dressing for unhealthy sores. We have found it of the greatest benefit in indolent ulcers and slowly healing sores after burns. Under its influence the flabby granulations soon give way to those of a florid red colour so characteristic of the healthy healing process.

A lotion consisting of a saturated watery solution of glacialine, sweetened with a little glycerine, is useful as a gargle in aphthous conditions of the mouth, tongue, and throat. The lotion also allays the tingling, itching, and burning sensation so common in certain stages of eczema; and used as an injection it is advantageously employed in irritable conditions of the vulva and vagina, and in some cases checks the amount of secretion in leucorrhœa. This valuable substance is supplied retail by chemists, and wholesale by the Glasgow Antitropic Company in neat cylindrical tins, and in a dry place will keep any length of time. Trusting you will find room for this communication,

We remain, Sir, yours, &c.,
J. STUART, M.D.,
Dowlais, Dec. 17th, 1880. E. DAVIES, L.R.C.P. Edin.

H. J. F. should apply by letter to the College. He would require a knowledge of inorganic and organic chemistry, for which Roscoe's work might be recommended.

Mr. G. P. Field.—Soon.

Juvenal.—We are unable to answer the various questions. The course to take is to write to the secretaries of the several companies.

Rickets.—This point is discussed in an article in our present number.

R. W. will find some information on the subject in a letter published in our present issue.

A Victim has not stated what part of Australia, concerning the climate of which he desires information.

SMALL-POX.

To the Editor of THE LANCET.

SIR,—In reference to the recent small-pox returns I cannot think but that much might be done against small-pox by more stringent isolation and disinfection. May I call your attention to two recent cases in this parish?

H. W——, twenty-six years of age, died on Nov. 2nd, 1880, and was buried on Nov. 5th, after a week's illness from small-pox. The house is a four-roomed one; there are five adults in it and a boy of ten years. Some disinfecting fluid was sprinkled about the house, and sulphur was burnt in the room in which the woman died. This was the only disinfection to which the bedding was subjected, and the flock mattress was not unpicked. The disinfector said his ovens were out of order.

The boy was attacked on the 14th, and I urged isolation, but the parents provided themselves with a certificate from the medical man in charge of the case, stating that this was not a case of necessary removal. Our medical officer of health was powerless to act without a certificate from the medical man to the effect that the boy could be removed without danger. I obtained this certificate on the 16th, and on the next day the ambulance was sent, but the parents took their stand on the first certificate, and revoked the verbal permission for removal which I had obtained from them.

I visited the house on the 26th, and found the boy convalescent, and his mother pursuing her business of dressmaking. There had not been any second disinfection up to this time.

In another case a boy of two years was attacked. The grandmother went to the medical officer of health to get him removed, but he was unable to interfere, as Highgate refuses to admit a child under six years, so he referred her to the relieving officer. The relieving officer refused to remove the case because they were not paupers. After two days through the influence of a guardian, the case was removed by the parish There were six other children in the house in this case, one of three rooms.

I am, Sir, yours obediently,
JAMES MAHOMED,
Dec. 17th, 1880. Curate of St. Philip's, Stepney.

DRINKING TROUGHS.

DR. BREWER has been making everybody who possesses a horse in the metropolis uncomfortable by urging the very probable occasional spread of glanders through the medium of public drinking troughs. The Special Purposes and Sanitary Committee of the Metropolitan Board of Works has had this subject under consideration, and has submitted the following recommendation to the Board:—"That it be suggested to the Metropolitan Drinking Fountain and Cattle Trough Association, and other bodies and persons who provide public drinking troughs in the metropolis, that such drinking troughs should be so constructed and used as to have a constant flow of water passing through them and running off by means of a tumbling bay, direct to a gully; and that measures should be taken to ensure the troughs being thoroughly cleansed every morning." This recommendation has been adopted.

Mr. Wm. Hunter, M.B. and C.M.—Our correspondent is right. The qualifications he mentions do not legally carry the title of physician and surgeon, but surgeon and apothecary.

A Trained Nurse's letter is too long for insertion.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Brunton, London; Mr. Whipple; Dr. Taylor, Ulverstone; Mrs. Napton; Dr. De H. Hall, London; Dr. Hollis, Brighton; Mr. J. Cæsar, London; Dr. Amidon, New York; Dr. Lewins, London; Dr. Savage, Birmingham; Abow Ben Adham; Dr. Murphy, Sunderland; Captain Blount; Dr. Roedl, Frangensbad; Mr. Craigie, London; Dr. Herman, London; Surgeon-Major S. Smith; Mr. Mayer, New York; Dr. Finch, Salisbury; Dr. Ormsby, Leeds; Messrs. Richardson, Leicester; Dr. Rorke, Wigan; Dr. Jordan, Birmingham; Dr. Gerrish, Portland, U.S.A.; Dr. Day, Japore; Dr. Eastwood, Darlington; Dr. Finch, Salisbury; Mr. Learn; Dr. Smith, Dumbarton; Mr. Davey, Lincoln; Dr. Jones; Mr. Head, Plymouth; Mr. Grant, Kirk Micheal; Dr. Fenn, Richmond; Dr. Rasch, London; Dr. De Bartolomé, Sheffield; Professor Brown-Séquard, Paris; Mr. Hosking, Penzance; Mr. Wiseman; Mr. F. Medical Diary for the ensuing Week.

Monday, Jan. 3.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

Tuesday, Jan. 4.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar, "On Atoms."

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M.—Annual General Meeting. The following Specimens will be shown:—Rheumatism and Gout in the same subject; Diseased Kidneys from a Pig; On the Pathological Histology of Molluscum Contagiosum; Molluscum Contagiosum; Obstruction of Mesenteric Artery and Vein; Case of Strangulated Hernia; Recurrent Multiple Sarcoma; Enlargement of the Median Nerve (living specimen); Calcareous Aorta (card); Acute Inflammation of Muscle.—Annual Report of the Council. Election of Officers.

Wednesday, Jan. 5.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

EPIDEMIOLOGICAL SOCIETY. — 7 P.M. Council Meeting. 8 P.M. Surgeon-Major Charles Oldham, "On the Nature and Origin of Climatic Fevers." Dr. J. Wm. Mackenna, "On the Cause and Origin of Fever."

OBSTETRICAL SOCIETY OF LONDON.—Meeting postponed from January 5th to January 12th.

Thursday, Jan. 6.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar, "On Atoms."

HARVEIAN SOCIETY.—8½ P.M. Annual Meeting and President's Address.

Friday, Jan. 7.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, Jan. 8.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Dewar, "On Atoms."

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 3
TO CHINA AND INDIA		One Year,	1 16 10
TO THE COLONIES AND UNITED STATES		Ditto,	1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

ADVERTISING.

Books and Publications		£0	5	0
Official and General Announcements		0	5	0
Trade and Miscellaneous Advertisements		0	4	6
(Seven lines, each averaging ten words, or seventy words in all).				
Every additional Line		0	0	6
Front Page	per Line	0	1	0
Quarter Page		1	10	0
Half a Page		2	15	0
An entire Page		5	5	0

The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

A Lecture
ON
THE DIFFERENTIAL DIAGNOSIS OF CARDIAC MURMURS.

Delivered in the Extra-Academical School of Medicine, Edinburgh,

BY BYROM BRAMWELL, M.D., F.R.C.P. EDIN.,
LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, AND ON PRACTICAL MEDICINE AND MEDICAL DIAGNOSIS IN THE EXTRA-ACADEMICAL SCHOOL OF MEDICINE, EDINBURGH; LATE PHYSICIAN AND PATHOLOGIST TO THE NEWCASTLE-ON-TYNE INFIRMARY.

GIVEN the presence of a murmur in the præcordial region, we have to determine:—

A. Whether it is *exo*cardial or *endo*cardial.

B. If exocardial, whether it is a pleural, pericardial, or pericardial-pleural murmur.

C. If endocardial:

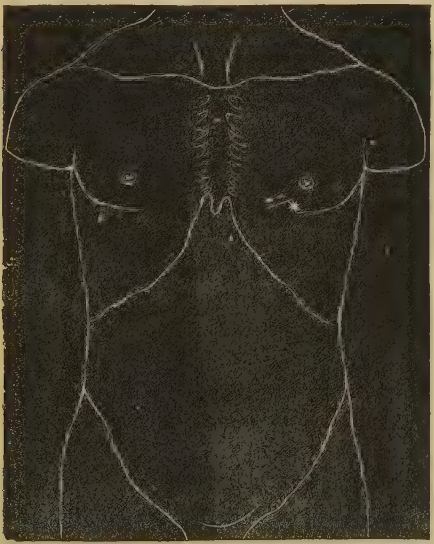
1. The valve at which it is produced, and whether it is direct or regurgitant.
2. Whether it is organic or functional.
3. If organic, the extent and gravity of the lesion.

The differential diagnosis of exocardial and endocardial murmurs is, as a rule, easily made by attention to the following points:

1. *The rhythm of the murmur.*—Pleural friction sounds are, of course, at once distinguished from cardiac murmurs by the fact that they correspond in frequency to inspiration and expiration, and that they do not correspond with the pulsations of the heart.

Exocardial murmurs (pericardial friction and pericardial-pleural friction murmurs) do correspond in frequency with the pulsations of the heart, but their synchronism is, as a rule, much less perfect (they do not correspond so exactly with the heart sounds) than the synchronism of endocardial murmurs.

FIG. 1.

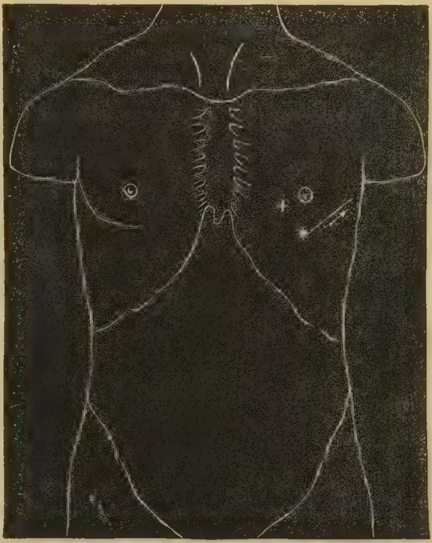


Outline figure showing the point of differential maximum intensity (*) of the presystolic mitral murmur (mitral stenosis), and the direction in which it is propagated.

Pericardial murmurs, when typical, are double (the to-and-fro friction murmur of pericarditis), but the murmur of combined aortic stenosis and incompetence is also double; hence in the majority of cases the problem resolves itself into the differential diagnosis of these two conditions (pericarditis and double aortic disease).

The *rhythm* of exocardiac murmurs is often *variable*, is apt to change from day to day, from hour to hour, or even during the actual examination of the patient. Alterations in the relative position of the two opposed surfaces of the pericardium, such as may be produced by alterations in the position of the patient, by the application of pressure to the præcordia through the stethoscope, frequently modify the character (rhythm and position) of pericardial murmurs.

FIG. 2.

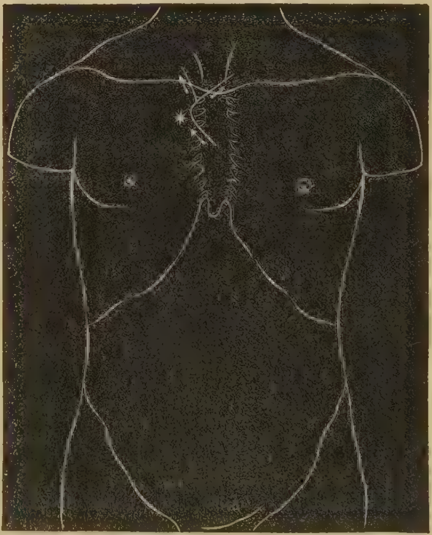


Outline figure showing the point of differential maximum intensity (*) of the systolic mitral murmur (mitral regurgitant), and the direction in which it is propagated. + indicating the normal position of the nipple, is perhaps a shade too high.

Endocardial murmurs are not variable, but fixed.[1]

Endocardial murmurs, with the exception of the presystolic murmurs, replace more or less completely the cardiac sounds. (See below, Rhythm of Endocardial Murmurs.) Pericardial murmurs accompany and may obscure the cardiac sounds, but do not replace them.

FIG. 3.



Outline figure showing the point of differential maximum intensity (*) of the systolic aortic murmur (aortic stenosis), and the direction in which it is propagated.

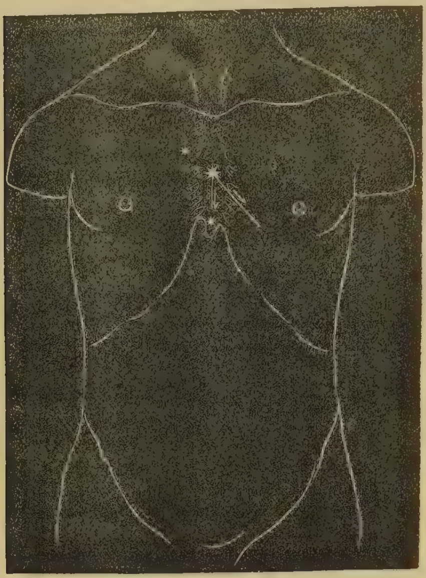
It is sometimes difficult to say whether a cardiac sound is replaced or only obscured by the murmur. In such cases the sound may sometimes be distinguished by removing the ear a short distance from the end of the stethoscope, or by so placing the stethoscope that the ear-piece only partly covers the external auditory meatus.

---

[1] In some cases of mitral stenosis the murmur disappears when the position of the patient is altered, when he gets up, but the rhythm of the murmur does not change: it always remains presystolic.

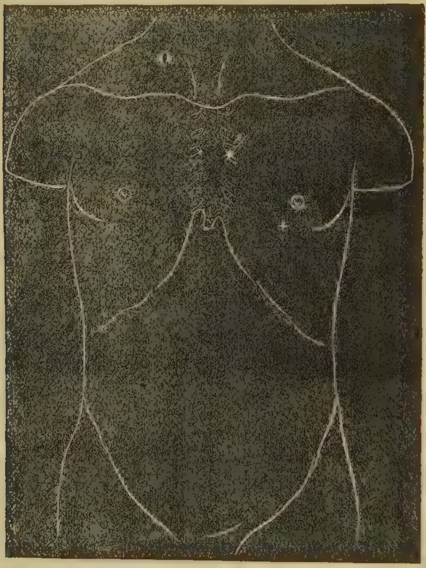
2. *The sound characters of the murmur.*—Exocardial murmurs are friction murmurs, and, as a rule, have a harsh, grating character. In some cases where the heart is acting feebly, and the lymph between the two opposed surfaces of pericardium is yielding—i.e., recent—the pericardial murmur is soft, closely resembling the sound characters of many double aortic murmurs. An exocardial murmur appears to be superficial. This is not a point of much importance, for many endocardial murmurs have the same character.

FIG. 4.



Outline figure showing the point of differential maximum intensity (*) of the diastolic aortic murmur (aortic regurgitation), and the direction in which it is propagated.

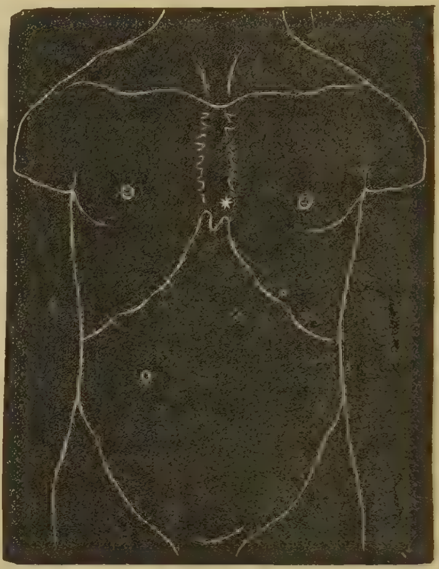
FIG. 5.



Outline figure showing the point of differential maximum intensity (*) of the systolic pulmonary murmur, and the direction in which it is propagated.

3. *The point of maximum intensity of the murmur, and the direction in which it is propagated.*—Exocardial murmurs are, as a rule, best heard over the borders of the heart, but have no special point of maximum intensity. Endocardial murmurs are, on the contrary, generally heard loudest at certain definite points. Mitral murmurs, for example, have their point of maximum intensity over the apex. (See Figs. 1 and 2.) Exocardial murmurs are usually heard over a limited, sometimes a remarkably limited, area, and are not propagated in the course of any particular blood-current, as endocardial murmurs are. (See Figs. 1, 2, 3, and 4.) The regurgitant aortic murmur, for example, is propagated downwards, the direct aortic murmur upwards over the course of the aorta, and into the vessels of the neck. (See below, Propagation of Endocardial Murmurs.)

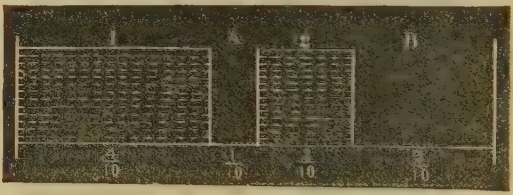
FIG. 6.



Outline figure showing the point of differential maximum intensity (*) of the systolic tricuspid murmur (tricuspid regurgitation).

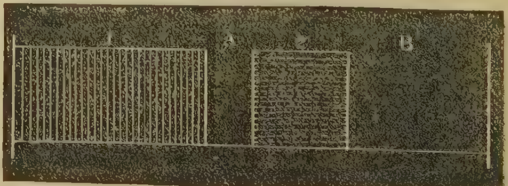
GRAPHIC REPRESENTATION OF CARDIAC MURMURS.

FIG. 7.



Graphic representation of one complete (normal) cardiac revolution. The sounds are represented by shaded (horizontally dotted) spaces, the pauses by blank spaces. 1=the first sound, 4-10ths; 2=the second sound, 1-10th. A=the short pause, 2-10ths; B=the long pause, 3-10ths.

FIG. 8.



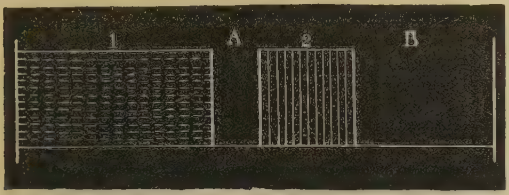
Systolic murmur replacing the whole of the first sound. The murmur in this and the succeeding figures is represented by continuous vertical lines, the normal sound by dotted horizontal lines.

4. Exocardial murmurs (pericardial and pericardial-pleural) appear abruptly (acutely, so to speak), and, as a rule, occur in the course of some general affection, rheumatic fever for example. Endocardial murmurs may appear abruptly, and in the course of rheumatic fever, &c., but in many cases it is impossible to fix the date of their occurrences (see foot-

note). The absence of constitutional disturbance, and the fact that the murmur is an old one, point strongly, therefore, to its being endocardial.[2]

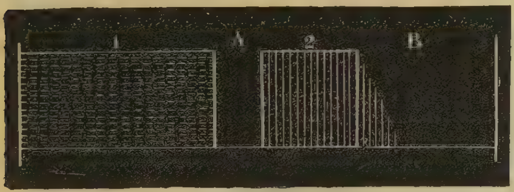
5. In the case of the double aortic murmur, which is the endocardial murmur, which is most liable to be mistaken for a pericardial friction murmur, the jerking, collapsing character of the pulse is a valuable diagnostic guide. The pulse in aortic cases is, as a rule, normal, or only slightly increased in frequency. In pericarditis it is usually accelerated. The symptoms may afford some corroborative evidence. In pericarditis there is, as a rule, some pain and tenderness on pressure. In cases of valvular disease there is seldom pain and tenderness, unless in aortic cases, in which the pain is usually angina-like in character.

FIG. 9.



Diastolic murmur replacing the second sound.

FIG. 10.



Diastolic murmur replacing the second sound, and extending into the long pause.

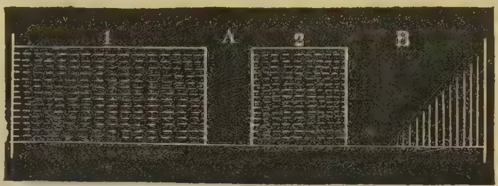
The murmur is exocardial. We have now to determine whether it is a pleural, pericardial, or pericardial-pleural murmur.

Ordinary pleural friction is at once distinguished by its rhythm corresponding to the respiratory movements.

It is sometimes extremely difficult to distinguish pericardial friction and pericardial-pleural friction.

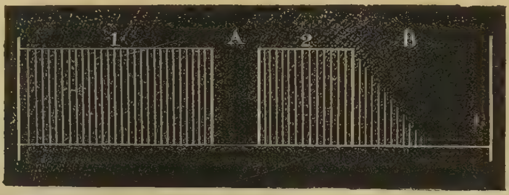
Pericardial-pleural friction is rare. It occurs when that portion of the pleura which is reflected over the pericardium is inflamed, and is produced by the movements of the heart rubbing this rough and inflamed portion of pleura against the chest-wall, or against the visceral pleura which is in contact with it. (The visceral pleura is usually inflamed, too.)

FIG. 11



Presystolic murmur occurring during the long pause, and ending abruptly with the commencement of the first sound. In this case the first and second sounds are represented as normal.

FIG. 12

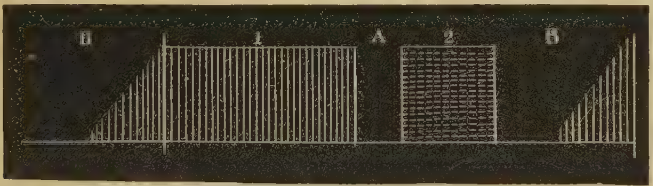


Systolic murmur replacing and limited to the period of the first sound; diastolic murmur replacing the second sound, and extending into the long pause.

1. Pericardial-pleural friction is generally best heard over the borders of the heart—i.e., where the visceral and parietal portions of the pleura are in contact.

2. Pericardial-pleural friction is, as a rule, more affected by the respiratory movements than ordinary pericardial friction. I have twice observed it decidedly increased during inspiration—i.e., when a larger surface of the two opposed and inflamed portions of pleura came in contact.

FIG. 1



Presystolic and systolic murmurs.

Walshe states that it is usually increased during expiration. Where this is the case, the murmur is probably produced by friction between the outside of the pericardium and the chest-wall, but not between the outside of the pericardium and the visceral pleura.

3. The pericardial pleural friction murmur is even more variable than pericardial friction, and may cease with certain pulsations of the heart.

4. On full and rapid inspiration it may disappear and be merged into ordinary pleural friction. This is not, however, pathognomonic, for ordinary pericarditis is frequently accompanied by pleurisy, and in such cases the pericardial friction may be *masked* (it does not disappear) by the pleural friction sound.

The murmur is endocardial. At which valve is it produced, and is it direct or regurgitant?

We determine these points by regarding:

(a) *The point of maximum intensity of the murmur*—or rather the point of *differential* maximum intensity for all valvular murmurs—may sometimes be heard with great intensity immediately over the valves. According to Walshe, "a superficial area of half an inch square will include a portion of all four sets of valves *in situ*: an area of about one-quarter of an inch, a portion of all except the tricuspid."[3] The points of differential maximum intensity for the different valves are as follows:

Mitral = the apex (see Figs. 1 and 2), *wherever it may be*; not necessarily in the fifth left interspace, an inch and a half below and slightly internal to the left nipple.

Aortic = second right costal cartilage (aortic cartilage)—i.e., that point where the aorta is most superficial. (See Figs. 3 and 4.) The aortic diastolic murmur is often heard loudest at the lower end of the sternum. (See below, Direction of Propagation of Murmurs.)

Pulmonary = third left costal cartilage (pulmonary cartilage), at its junction with the sternum. (See Fig. 5.)

Tricuspid = lower end of the sternum, or rather the junction of the lower left cartilages with the sternum.

A systolic murmur is sometimes heard equally loud both at the base and the apex, and it comes to be a question whether there are two or whether there is only one murmur.

In such cases (1) the murmur must be carefully traced from one point to the other (from the apex to the aortic cartilage, for example). If the intensity of the murmur be diminished at a point between the two positions there are probably two murmurs.

---

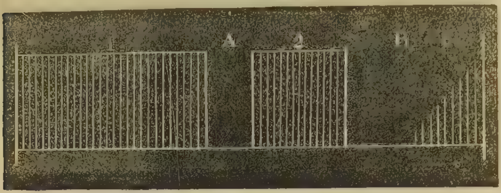
[2] If the murmur is present at the first examination, and if the patient has not been previously under observation, it may be impossible to say whether it is *recent* or not.

[3] Walshe, Diseases of the Heart p. 6.

(2) The tone of the murmur at the two points must be carefully noted. If the tone differs there are two murmurs.

(3) The direction of propagation must be observed. If the murmur is propagated both upwards towards the axilla and upwards over the aorta and into the vessels of the neck there are two murmurs.

FIG. 14.



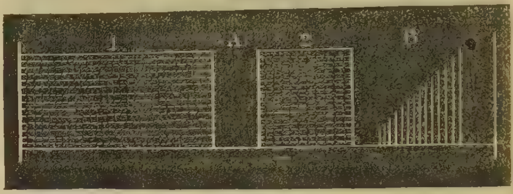
Presystolic, systolic, and diastolic murmurs.

(*b*) *The rhythm of the murmur.*—Endocardial murmurs are either systolic, diastolic, or presystolic.

Systolic and diastolic murmurs replace more or less completely the first and second sounds respectively, and may extend more or less into the first and second silences. (See Figs. 8, 9, and 10.) Presystolic murmurs do *not* replace either sound, but occur solely during the long silence, towards its end, immediately before the ventricular systole. (See Fig. 11.)

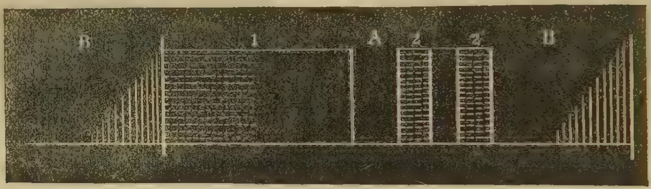
When the heart is acting quickly it may be very difficult or impossible to "time" the murmur correctly. The difficulty of determining the exact rhythm of the murmur is also increased where there is a combination of murmurs such as I have represented in Figs. 12, 13, and 14. This is more especially the case where a presystolic and systolic mitral are combined, as in Fig. 13. The difficulty is less in the combined aortic murmurs. In the latter case there is nearly always an appreciable interval between the systolic and diastolic portions of the murmurs, as seen in Fig. 12.

FIG. 15.



Post-diastolic murmur, which occurs in some rare cases of mitral stenosis. It is separated from the commencement of the first sound by an appreciable interval. Compare with Fig. 11, which represents the usual typical presystolic murmur of mitral stenosis.

FIG. 16.



Graphic representation of the cardiac cycle in a typical case of mitral stenosis—viz., presystolic murmur, short valvular first sound, reduplicated second sound.

Figs. 8 to 14 are intended to be graphic representations of the various cardiac murmurs. Fig. 7 represents the normal cardiac cycle, showing the relation of the sounds and silences. In the succeeding figures the interrupted horizontal lines represent the normal cardiac sounds; the continuous vertical lines the new sounds or murmurs. These diagrams are, I think, superior to the usual graphic representations of cardiac murmurs, inasmuch as the time relations of the cardiac sounds and silences are accurately preserved.

SYSTOLIC MURMURS.

A systolic mitral murmur=mitral regurgitation.

A systolic aortic murmur=aortic stenosis, roughening, or (?) anæmia.

A systolic pulmonary murmur = pulmonary stenosis, roughening or (?) anæmia.

A systolic tricuspid murmur=tricuspid regurgitation.

DIASTOLIC MURMURS.

An aortic diastolic murmur=aortic regurgitation. *A pulmonary diastolic murmur*=pulmonary regurgitation (infinitely rare).

PRESYSTOLIC MURMURS.

A mitral presystolic murmur=stenosis or roughness of the mitral orifice.[4] *A tricuspid presystolic murmur*=stenosis or roughness of the tricuspid orifice (infinitely rare).

(*c*) *The direction in which the murmur is propagated.*—Murmurs are propagated either by (1) *diffusion*—i. e., in all directions through the structures within the thorax, a method which is of little value or importance, or—

(2) *Conduction* through solid structures.

(3) *Convection* carried by fluid *in the direction in which it is flowing.* A most important mode of propagation for our present purpose.

The following are the directions in which the chief endocardial murmurs are propagated by convection :—

Mitral regurgitant murmurs, upwards and towards the left axilla (see Fig. 2); often well heard at the inferior angle of the left scapula. According to George Balfour and others, the chlorotic murmur heard in the pulmonary area is a mitral regurgitant murmur (see below), and propagated to this situation through a dilated auricle.

Mitral direct murmurs, forwards and downwards, usually only to a very limited extent. (See Fig. 1.)

Aortic regurgitant murmurs, downwards in the direction of the cavity of the ventricle; but since the sternum is such a good sound conductor of sound the murmur of aortic regurgitation is well propagated along and often best heard at the lower end of that bone. (See Fig. 4.)

Aortic direct murmurs, upwards along the course of the aorta and into the great arteries of the neck. (See Fig. 3.)

Pulmonary regurgitant murmurs (infinitely rare), downwards towards the lower end of the sternum.

Pulmonary direct (very rare), deeply into the chest; and hence their direction cannot, as a rule, be traced for any distance on the surface of the chest. (See Fig. 5.)

Tricuspid regurgitant, backwards and upwards towards the right axilla, but not over the course of the aorta, nor into the vessels of the neck.

Tricuspid direct (infinitely rare?), forwards and downwards and to the left, but only to a very limited extent.

(*d*) *The sound characters of the murmur* are of comparatively little importance, except in the case of the presystolic murmur, which presents peculiar and characteristic features.

Direct murmurs are usually louder and harsher than indirect murmurs. Much, however, depends upon the force of the blood-current (i.e., the force of the heart) which produces the murmur.

---

[4] The murmur of mitral stenosis is sometimes rather post-diastolic than presystolic—i. e., it occurs during the first period of the long pause, and is separated from the first sound by an appreciable interval. (See Fig. 15.) In such cases there is probably something which prevents the final forcible and complete contraction of the auricle, which is the active agent in the production of the ordinary typical presystolic murmur.

The mitral presystolic murmur commences gradually, increases in intensity, and ends abruptly with the occurrence of the first sound. It is rough. The first sound which follows it is altered in character, has lost its normal dull tone and has become shorter and sharper, more like a second sound, for which it is often mistaken. The second pulmonary sound is accentuated and often reduplicated. (See Fig. 16.)

The alteration in the character of the first sound, which is observed in cases of mitral stenosis, is due to the small amount of blood which gets into the left ventricle. The first sound as heard over the right ventricle is of normal tone.

The chief characters of the murmurs which are observed in connexion with the different valvular lesions are shown in the table to be given in the concluding part of the lecture.

(*e*) *The effect of the lesion on the heart and circulation.*—In the case of organic murmurs this is of great importance, and in doubtful cases affords most valuable evidence as to the nature of the lesion. It will, however, be more convenient to consider this point when speaking of the character of the lesion. (See below.)

(*f*) The relative frequency of the different valvular lesions may be of value in some cases—as, for example, in deciding whether a murmur is aortic or pulmonary. It must always be remembered that organic lesions in the adult (i.e., primary organic lesions) are in the vast majority of cases left-sided.

(To be concluded.)

IVORY EXOSTOSIS IN BOTH EARS SUCCESSFULLY REMOVED BY OPERATION.

BY GEORGE P. FIELD, M.R.C.S.,
AURAL SURGEON TO ST. MARY'S HOSPITAL.

TWO years ago I published in THE LANCET a case of ivory exostosis in both ears, in which I had successfully operated with the American dental engine. This instrument is, I believe, the only one which will penetrate with any certainty such pre-eminently hard and unyielding growths of the petrous bone. For this mode of treatment we are indebted to Dr. Arthur Mathewson of Brooklyn, New York, who kindly sent me his paper on the subject.[1] I operated in my former case seven times on large ivory growths, completely filling up both ears. The patient was seven hours in all under chloroform and ether. No one can imagine, unless he has actually drilled into these dense tumours, their adamant-like consistency, and the great difficulty there is in making any impression on them.

Toynbee and others consider that these growths are invariably found in gouty and rheumatic subjects; whilst other authors, such as Triquet, think they are only seen in syphilitic patients; and Gruber believes such diseases may influence their production. In the cases I have seen there has, in no single instance, been discovered any trace of gout or syphilis. I rather believe they are more often due to a chronic inflammation of the walls of the external meatus, such as I think might be produced from sea-bathing. It is a remarkable fact that in both my cases of double ivory exostosis the patients were in the habit of bathing constantly day after day in the sea, and they both attributed their ear mischief to this cause alone. The aquatic habits of the Hawaiian islanders are well known;[2] and Dr. C. T. Blake (quoting Professor Wyman) has pointed out the frequent presence of exostoses in the external auditory meatus observed in the crania of these people. As it has been well put, "A mechanical irritation continued for a long time, on any part whatever of the osseous auditory meatus, can give rise at that place to an osseous tumour."[3]

Von Tröltsch is of opinion that considerable pain is always felt in bony tumours of the meatus when touched; in the case (Miss H——), which I shall relate further on, there was certainly great pain produced from the slightest touch by a probe. On the other hand, I have remarked that the true ivory exostosis may be examined with instruments without causing the slightest pain. The true ivory exostosis is usually bilateral, covered with white, smooth skin and hairless; it is of ivory consistency, and arises near the orifice of the meatus. Such growths, as I have before pointed out, in other parts of the body would be called hyperostoses. Their development is insidious, and they occur in apparently healthy organs. Their very existence is not suspected until the patient discovers that his hearing is rapidly failing him, while the absence of pain might lead him to regard it at first as a trivial matter. "The ivory exostosis has been observed to be much more common in men than in women. It arises from a broad base in the posterior wall of the external meatus, either as a long bony ridge or as a normal tumour or tumours. This form is acquired, and not congenital. Its growth is not rapid, nor have we often any signs of inflammation, until the patient becomes suddenly deaf from the complete occlusion of the meatus and consequent irritation set up thereby." The pedunculated form of exostosis, on the other hand, is rapid in growth and the suppuration is plentiful and very offensive.

When ivory exostoses are multiple they do not, as a rule, cause a great amount of deafness. They are smaller in size, and are not confined to the posterior wall. Three of them are often found growing from opposite sides; they become so wedged into one another that they cannot close up altogether, and a triangular space is therefore left between their apices.

These smaller multiple exostoses are usually found nearer to the membrana tympani. A gentleman, Mr. R—— of Cambridge, lately consulted me for slight deafness, who had three exostoses in the right ear, and two in the left. In the right ear there was a triangular aperture left, and it is a remarkable fact that these multiple excrescences do not entirely fill up the canal, for there is always sufficient space left between them for the passage of sound. But the opening left is necessarily small, and the patients are often very deaf, for any slight obstruction caused by cerumen, or even water, will effectually shut out sound. To remove the obstruction in such a narrow passage is not an easy matter. Some time ago a clergyman, the Rev. Dr. M——, consulted me for extreme deafness in both ears, of long standing, caused by a filling up by cerumen of the spaces left between multiple exostoses, three in each ear, and who afterwards heard very fairly when I had cleared the stricture. In September, 1880, I saw Dr. G—— of Limerick, who came to show me his multiple exostoses, and who had entirely regained his hearing after a long period of deafness, under the skilful hands of Dr. Macnaughton Jones of Cork.

Professor Gruber has found obliteration of the Eustachian tube from osseous tissue developed in its walls. In most cases of aural exostoses this is not my experience, as I have never seen an example of the kind. Cases have been recorded, called ivory exostoses, in which, by drilling here and drilling there and then using the bone forceps, the tumour has been removed, the whole operation lasting no longer than twenty minutes. The following is, I believe, a case in point, and a good illustration of the same operation. Miss H——, aged twenty-four, in good health, with no history ot any kind of deafness in her family, was sent to consult me on June 1st, 1880, by Dr. Gibson of Hull. She had a hard bony growth, which looked something like a small snail-shell, and almost filled up the orifice of the right external auditory meatus. She could hear the watch one inch, and the tuning-fork much better, in the deaf ear. She would not allow a thorough examination to be made, as she complained of great pain when the bone was touched. The growth had been gradually increasing in size, and she had been slowly getting very deaf. On June 2nd, having placed the patient under chloroform, I proceeded to make a thorough examination. With the aid of a probe I found that the tumour arose from the anterior wall (said to be very rare), and near the orifice of the meatus, which it all but filled up. I then proceeded to use the dental engine, making a small hole in the base of the tumour, close up to the anterior wall. I then seized it with a strong pair of dressing forceps, and with little difficulty took it completely away. The whole operation lasted about fifteen minutes. In ten days' time the patient returned home, hearing perfectly well. This was soft bone, and very easily treated. Let anyone try to saw through the hardest part of the temporal bone, and the resistance offered in that case would give some idea of the difficulty of an operation on an ivory exostosis. The ivory exostosis is less vascular, and therefore harder even than other portions of the bone. Under the microscope the softer bone tumour from Miss H——'s ear, with a thin section under a low power, 75 diameters, shows that the growth is made up of material similar in structure to newly-formed bone. The free surface is bounded by fibrous membrane raised into small papillæ, and covered by squamous epithelium. In the substance of the tumour trabeculæ of bone form a sort of spongy tissue, in the meshes of which a vascular medullary tissue is contained. Magnified 350 diameters, the fibrous membrane shows no nerves or glands, and only a few small vessels. The layer of bone immediately beneath it is more condensed and thicker than the central portions. Its lamellæ are parallel to the surface, and contain but few bone corpuscles. In the central portion of the growth the trabeculæ are thinner and limit irregular oval spaces. These are filled in some parts with a richly nucleated fibrous tissue containing numerous spindle and round cells. In other parts there is but little fibrous tissue scattered in the midst of round cells. No giant-cells are seen anywhere. The vessels consist chiefly of very large thin-walled tubes, resembling dilated capillaries. They are well filled with blood. Here and there a few arterioles are visible.

[3] See Medical Press and Circular, July 9th, 79, paper by Dr. Delstanche, translated by Dr. Cassels.

The tumour differs from a true ivory exostosis in containing cavities filled with medullary tissue, and hence it may be termed "a spongy osteoma," as defined by Cornil and Ranvier. Some exostoses of pedunculated form may be removed by wire; in these suppuration is generally plentiful, and occasionally a polypus arising from the exostosis precedes its appearance, as in a case I published.[4] Kramer has described an interesting instance of a polypus in the form of a stalactite, so hard that a knife could not cut it. Clark of Bristol has removed by electricity an exostosis, which followed the growth of a mucous polypus, from the right ear of a girl nineteen years of age. But Bonnafont, I believe, was the first surgeon who dealt successfully with an ivory exostosis causing complete closure of the meatus. This was accomplished by means of graduated styles, and by the use subsequently of nitrate of silver. I have found this method of treatment almost unbearable, from the intense pain to which it gives rise. Tröltsch has successfully used laminaria to enlarge the opening between the growth and the wall of the auditory canal. Miot adopted another plan; he trephined the tumour with a very fine instrument in two or three places, set up suppuration, and dead bone afterwards came away in sufficient quantity to allow the membrana tympani to be seen. *(To be concluded.)*

ON SOME POINTS IN THE

PATHOLOGY AND TREATMENT OF ACUTE RHEUMATISM AND DIABETES.[1]

BY P. W. LATHAM, M.A., M.D., F.R.C.P.,
DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE,
PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

I PROPOSE to consider four questions :—

1. What is the starting-point of the morbid process in acute rheumatism?
2. Is there any pathological relationship between it and diabetes mellitus?
3. Will any remedy cure acute rheumatism; and
4. If so, how does the remedy act?

I think it will be conceded that these are questions of considerable interest, and well worth attention. The solution I am about to offer of the problems may not be altogether complete; but if there is no unreasonable improbability about the theory, it may at least be suggestive, and perhaps lead to further investigation.

1. What is the starting-point then of the morbid process? Let us turn our attention to the muscular tissue and consider for a moment the physiological changes which take place in that tissue in a state of health. The hæmoglobin of the venous blood as it passes through the lungs becomes wholly, or almost wholly, oxyhæmoglobin. Hurried to the tissues, the oxygen of the arterial blood passes from the blood into the muscular tissue; immediately it has passed it is then fixed in some way at present unknown to us; the tissue packs away at every moment each molecule of oxygen which it receives from the blood so as no longer to be removable by diminished tension. Out of the body the tension of oxygen in the muscle is *nil*, none can be obtained from it from the air-pump. The oxidation takes place in the muscle itself, oxygen passes into the tissue, but we cannot trace its sojourn there. On the other hand, the muscle is always producing and discharging carbonic acid, and when it contracts there is a sudden and extensive increase of the normal production of that gas. With much but not all of its oxyhæmoglobin reduced, the blood passes on as venous blood, and with its carbonic acid tension increased it arrives in the lungs, where the gas is discharged.[2]

This change now in the muscular tissue, the fixing of oxygen and exhalation of carbonic acid, must be regulated by some nervous mechanism, in the same way, for instance, as the blood is prevented from coagulating in its vessels or the stomach from digesting itself; and this power must originate in some nervous centre, which we may call the "inhibitory chemical centre," or, using a more applicable term, the "coördinating chemical centre"—the centre which restrains chemical action and regulates the production of heat. "And, indeed, we have some positive evidence of the existence of such a mechanism."[3]

Suppose this "coördinating chemical centre" has undergone functional or organic change, and that this regulating action is consequently weakened or removed, what would be the result? Instead of the muscle absorbing and fixing oxygen and giving out carbonic acid, some intermediate changes in the tissue would show themselves; the tissue would be disintegrated and oxidised more vigorously, and those changes would take place, in some degree at least, which in the laboratory are seen to result from decomposition or the action of oxygen or ozone. And what are those changes? One of the first is that the reaction of the tissue becomes acid. "Whilst muscle is alive and in a physiological condition it possesses a neutral reaction to test-paper; so soon as it dies this reaction becomes acid, and this takes place so rapidly in warm-blooded animals, as to render it almost impossible to ascertain the normal reaction."[4] The acid produced is lactic acid. Whence is it derived? Muscle we know contains a small amount of glycogen, which by hydration may be converted first into glucose and then into lactic acid.

$$\underset{\text{Glycogen.}}{C_6H_{10}O_5} + \underset{\text{Water.}}{H_2O} = \underset{\text{Glucose.}}{C_6H_{12}O_6} = \underset{\text{Lactic acid.}}{2C_3H_6O_3} \text{ or } \underset{\text{Acetic acid.}}{3C_2H_4O_2}$$

$$\underset{\text{Lactic acid.}}{2C_3H_6O_3} + \underset{\text{Oxygen.}}{6O_2} = \underset{\substack{\text{Carbonic}\\ \text{anhydride.}}}{6CO_2} + \underset{\text{Water.}}{6H_2O}$$

Again, lactic acid may be derived from alanine, a substance metameric with urethane and sarcosine, $C_3H_7NO_2$.

$$\left\{\underset{\text{Urethane.}}{CO(NH_2)OC_2H_5} \text{ or } \underset{\text{Alanine.}}{C_2H_4(NH_2)CHO_2}\right\} + \underset{\text{Water.}}{H_2O} = \underset{\text{Lactic acid.}}{C_3H_6O_3} + \underset{\text{Ammonia.}}{NH_3}$$

Sarcosine, though not found in a free state in the body, is obtained in the laboratory from dead muscle. Nor is it inconceivable that under the action of chemical and *vital* forces acting upon the muscle, urethane or alanine, or it may be some other compound metameric with sarcosine, may be formed in the muscle as it passes from a state of health and activity to one of disintegration and death. At any rate, whatever be the source of lactic acid, whether from glycogen or other compounds in the muscle, we know that it appears in the muscle as the result of disconnexion with the nervous centre, and I therefore suggest that if the "inhibitory" or "coördinating chemical centre" be weakened, as in acute rheumatism, by the effect of cold or other cause, lactic acid instead of being oxidised in the muscle will pass from the tissue into the blood; and independently of its own conversion into carbonic acid and water in the blood, there produce its effect on the smaller arteries, and, by determining a larger amount of blood and oxygen to the part, cause more rapid oxidation of tissue, and develop considerable heat or pyrexia.

That the presence of lactic acid in the blood will determine a larger amount of oxyhæmoglobin to the tissue and cause more rapid transformation of tissue than normal, is a natural inference from the researches of Dr. W. H. Gaskell, who found that the injection of a solution of lactic acid (1 to 1000) into the circulation caused dilatation of the smaller arteries.[5]

[2] Text-book of Physiology by Dr. Michael Foster. 2nd edit., pp. 384-7.

[3] Foster, loc. cit., p. 376.

[4] Gamgee: Physiological Chemistry, vol. i., p. 359.

But if lactic acid is derived from some variety of $C_3H_7NO_2$, or from glycogen, whence comes the glycogen, or that other substance? Again, in acute rheumatism there is a large elimination of lithates—whence are they?

Let us turn our attention to the constituents of dead muscle. Creatine in dead muscle by hydration may be resolved into sarcosine and urea; and four molecules of sarcosine, together with nine atoms of oxygen, contain the elements of uric acid, glycogen, carbonic anhydride, and water.

$$\underset{\text{Creatine.}}{C_4H_9N_3O_2} + \underset{\text{Water.}}{H_2O} = \underset{\text{Sarcosine.}}{C_3H_7NO_2} + \underset{\text{Urea.}}{CH_4N_2O}$$

$$4C_3H_7NO_2 + O_9 = \underset{\text{Uric acid.}}{C_5H_4N_4O_3} + \underset{\text{Glycogen.}}{C_6H_{10}O_5} + \underset{\substack{\text{Carbonic}\\\text{anhydride.}}}{CO_2} + \underset{\text{Water.}}{7H_2O}$$

But as sarcosine is not found in living tissue, if urea, uric acid, &c., are products of living tissue, then there must be some undetermined compound of $4C_4H_9N_3O_2$ from which in living muscle these substances are produced, and from which in the process of dying sarcosine results.

Now, $C_3H_7NO_2$ represents sarcosine, urethane, and alanine, to which I will add a fourth, an entirely hypothetical compound—cyanic ether $+H_2O$.

$$\begin{aligned} C_3H_7NO_2 &= \underset{\text{Urethane.}}{CO,(NH_2),OC_2H_5} \\ &= \underset{\text{Alanine.}}{C_2H_4(NH_2)CHO_2} \\ &= \underset{\text{Sarcosine.}}{C_2H_4(CH_3)NO_2} \\ &= \underset{\text{Hypothetical compound.}}{CN,C_2H_5O,H_2O} \end{aligned}$$

To form the representative of sarcosine in the living tissue I want a very unstable compound, and one that is clear and fluid. Cyanic ether is a transparent, colourless, very mobile liquid, and is decomposed by water.

$$2\left\{\underset{\text{Cyanic ether.}}{CN,C_2H_5O}\right\} + H_2O = \underset{\substack{\text{Carbonic}\\\text{anhydride.}}}{CO_2} + \underset{\text{Diethyl carbamide.}}{N_2CO(C_2H_5)_2H_2}$$

And taking the other ether which the formula represents—viz., urethane—I have

$$\begin{aligned} 4C_3H_7NO_2 &= 2\left[\left\{\underset{\text{Urethane.}}{CO(NH_2)C_2H_5O}\right\}\left\{\underset{\text{Hypothet. compd.}}{CN,C_2H_5O,H_2O}\right\}\right] \\ 4C_3H_7NO_2 + O_9 &= \rule{9cm}{0.4pt} + O_9 \\ &= (NH_2)_2(CN)_2(CO)_3 + (C_2H_5O)_2C_2O_3 + CO_2 + 7H_2O \\ &= \underset{\text{Uric acid.}}{C_5H_4N_4O_3} + \underset{\text{Glycogen.}}{C_6H_{10}O_5} + \underset{\substack{\text{Carbonic}\\\text{anhydride.}}}{CO_2} + \underset{\text{Water.}}{7H_2O} \end{aligned}$$

By taking this as the living representative of $4C_3H_7NO_2$ we have a formula which, when oxidised, can theoretically be split up into uric ucid, glycogen, &c., and gives a molecular formula for them, and which, if there was a change in the constitution of the molecules, could produce sarcosine. The chief difficulty in accepting such an antecedent for sarcosine is that it involves the conversion of (NH_2) compounds into those of NO; and yet, from the researches of Dr. Bence Jones,[6] such a change does take place in the system, acetate of ammonia, when given internally, being eliminated as nitrates.

By combining cyanic ether with urethane we should probably have a compound somewhat like living muscle, which, as was shown by the observations of Kühne and Eberth,[7] who had the good fortune to see a living nematode freely moving about in it, is semifluid. Cyanic ether also combines with urea, forming a crystalline substance, which does not possess the characters of an ordinary ammonium compound.

It is not improbable that $4C_3H_7NO_2$ may exist in the tissue before hydration, as,

$$2\left[\left\{\underset{\text{Urethane.}}{CO\,(NH_2)\,C_2H_5O}\right\}\left\{\underset{\text{Cyanic ether.}}{CN,C_2H_5O}\right\}\right]$$

and so resembles uric acid in requiring hydration and oxidation to convert it into recognised substances. In order to convert uric acid into urea it must be combined with water and oxygen, the results differing according as an alkali or an acid is employed for the conversion. If hydration in the living body is performed in the liver, and oxidation in the muscular tissue, the following intermediate compounds between uric acid and urea would be developed. If hydrated in the liver—

$$\underset{\text{Uric acid.}}{(NH_2)_2(CN)_2(CO)_3} + \underset{\text{Water.}}{H_2O} = \underset{\text{Pseudo-uric acid.}}{(NH_4)(CNO)(NH_2)(CN)(CO)_3}$$

In alkaline fluid this substance would be oxidised in the tissue into allantoin $(NH_4)(CNO)(NH_2)(CN)(CO)_2 + CO_2$, and the allantoin would then be hydrated in the liver into urea $(NH_4)(CNO)$, and allanturic acid $(NH_4)(CNO)(CO)_2$ to be again oxidised in the tissue into urea and $2CO_2$.

If the blood had a different reaction uric acid after hydration in the liver would be split up into urea $(NH_4)(CNO)$ and $(NH_2)(CN)(CO)_3$, the urea passing off to the kidney, the other substance being oxidised in the tissue into alloxan $(NH_2)(CN)(C_3O_4)$, to be further hydrated in the liver, and split up into urea and mesoxalic acid $(H_2O)(C_3O_4)$.

It these substances, however, are formed by oxidation in the tissue, and by hydration in the liver, how is it that in health they appear only to a comparatively small extent in the blood? I will illustrate this by reference to electrolysis. In the decomposition of water by electrolysis oxygen appears at one pole, hydrogen at the other, and though the fluid between them appears to be at rest, we know there is a molecular change all along the line. In the transmission, likewise, of the current along the telegraph or telephone wire, there is a molecular change through the whole length of the wire, but the result is seen or heard only at the end. So it probably is in these transformations of the tissues. The blood acts as the conducting medium. It contains substances differing in their properties, but closely allied in chemical composition to those contained in muscle. Creatine, then, we may assume, is hydrated in the liver into urea and the representative of living sarcosine; these products are not set free, or only to a very small extent, in the blood, but there is an interchange of molecules in the blood between the liver and kidney on the one hand, and the liver and the tissue on the other. The change effected in the liver in this way shows itself only in the kidney and the tissue; the urea is eliminated, the living sarcosine appears in the tissue to be immediately oxidised, and to show itself in the liver as uric acid, glycogen, and carbonic acid gas, the last being liberated in the blood, and passing in the stream to be exhaled by the lungs. The uric acid and glycogen are now hydrated in the liver, the results showing themselves in the tissue and in the kidneys.[8] According as the blood is alkaline or otherwise will uric acid pass through the changes I have above referred to.

Now, a very interesting point arises. In considering the changes of uric acid above described we see that urea is formed both in the muscle and in the liver, and we may assume that when it is formed it passes at once by intermolecular change direct to the kidneys. So also we may assume that carbonic acid, whether formed in the muscle or in the liver, directly it is formed passes at once into the blood, to be eliminated by the lungs. Glycogen $(C_2H_5O)_2C_2O_3$ by hydration is transformed into glucose $(C_2H_6O)_2(CO_2)_2$, and, like uric acid, may, under different circumstances, undergo different transformations. If the blood is normal and alkaline by hydration in the liver it may become $(C_2H_6O)_2 + 2CO_2$, the carbonic acid at once entering the blood, the alcohol $(C_2H_6O)_2$ appearing in the tissue, to be oxidised into $4CO_2 + 6H_2O$; passing, perhaps, through the stage of $(C_2H_4O_2)_2$ acetic acid, and $2H_2O$.

But if the blood is in an abnormal condition the interchange of the molecular elements may be modified (and the alkaline reaction of blood becomes, like muscle, changed when the power of the coördinating centre is removed, as shown in the process of coagulation), the glycogen $(C_2H_5O)_2C_2O_3$ may then be hydrated in the liver and, as the result of the variation in the molecular interchange in the blood, appear in the tissue either as glucose $2(C_2H_6O)CO_2$, or as lactic acid $2C_3H_6O_3$, which last we know does appear in muscle when the power of the coördinating centre is removed.

---

[5] Journal of Physiology, vol. iii., p. 18.

[6] Philosophical Transactions, London, 1851.

[7] Gamgee, op. cit., p. 320.

[8] Assuming such an interchange of molecular particles, does not this offer a simple explanation of one mode of nutrition and disintegration of the tissues?

The following substances, with others, would exist in the liver and tissue (urea and carbonic acid being eliminated as formed), according as the blood had a normal alkaline or abnormal reaction :—

IN LIVER.		IN TISSUE.		
$4C_4H_9N_3O_2$	hydrated into	Urea + $[\{CO(NH_2)C_2H_5O\}\{CN,C_2H_5O,H_2O\}]$	oxidised into	Uric acid, glycogen, carbonic acid, and water.

TABLE I. — *Blood Normal.*

$(NH_2)_2(CN)_2(CO)_3$ Uric acid.	into		$(NH_4)(CNO)(NH_2)(CN)(CO)_3$ Pseudo-uric acid.	into	Allantoin and CO_2
$(C_2H_5O)_2(C_2O_3)$ Glycogen.	into		$2C_2H_6O$ Alcohol.	into	$4CO_2+6H_2O$ or $2(C_2H_4O_2)+2H_2O$ Acetic acid.
$(NH_4)(CNO)(NH_2)(CN)(CO)_2$ Allantoin.	into	Urea +	$(NH_4)(CNO)(CO)_2$ Allanturic acid.	into	Urea + $2CO_2$

TABLE II. — *Blood Abnormal.*

$(NH_2)_2(CN)_2(CO)_3$ Uric acid.	into	Urea +	$NH_2(CN)(CO)_3$	into	$(NH_2)(CN)(C_3O_4)$ Alloxan.
$(C_2H_5O)_2(C_2O_3)$ Glycogen.	into		$2(C_2H_6O)(CO_2)$ or $2C_3H_6O_3$ Glucose. Lactic acid.	into	$6CO_2+6H_2O$
$(NH_2)(CN)C_3O_4$ Alloxan.	into	Urea +	$(H_2O)(C_3O_4)$ Mesoxalic acid.	into	$3CO_2+H_2O$ or $(H_2O)(C_2O_3)+CO_2$ Oxalic acid.

Consequently, if the power of the coördinating centre is removed or impaired, we should have, as shown in Table 2, simultaneously in the liver, and as the last stage in the process, glycogen about to be transformed, and appear in the tissue as lactic acid or as glucose, and alloxan about to be split up into urea and mesoxalic acid; and to this point I shall refer when dealing with the action of remedies.

It would seem from these hypotheses that in a state of health glycogen and glucose are abnormal constituents of muscle, the liver glycogen appearing in the tissue as $2C_2H_6O$, to be at once transformed into CO_2 and H_2O. But, if the controlling power is weakened, glycogen is transformed, and appears in the tissue as lactic acid or glucose, according to the extent to which that power is weakened, and according to the variation in the molecular change along the blood line; and these substances may also, from the same causes, appear in the blood itself. If lactic acid produces the same effect on the smaller arteries of the kidney as was seen in the experiments of Dr. Gaskell to be the effect on those of muscular tissue, and so (under certain conditions of the red blood-corpuscles to be presently referred to) act as a diuretic, the experiments of Claude Bernard seem to support very strongly the view I have here advanced as to the common origin of glucose and of lactic acid. "When we prick the mesial line in the floor of the fourth ventricle, in the centre of the space between the origins of the auditory and pneumogastric nerves we at the same time produce an exaggeration of the hepatic (saccharine) and of the renal secretions; if the puncture be effected a little higher, we very often only produce an augmentation in the quantity of the urine, which then frequently becomes charged with albuminous matters; while if the puncture be below the indicated point, the discharge of sugar alone is observed, and the urine remains turbid and scanty. . . . As these two points are very near one another, it often happens that if the instrument enters obliquely they are simultaneously wounded, and the animal's urine not only becomes superabundant but saccharine."[9]

Lastly, though it is most probable that in health the various substances are oxidised in the tissues and not in the blood, yet where there are morbid changes and abnormal products appearing in the blood, if the energy of the red blood-corpuscles as carriers of oxygen from the lungs is not lessened it seems hardly possible that oxidation of oxidisable substances should not take place there. How else can the conversion of vegetable acids be explained, which, when administered internally, are eliminated as carbonates? In acute rheumatism it would seem probable, therefore, that there is increased heat or pyrexia, partly by increased oxidation in the tissue from the smaller arteries dilating, owing to the presence of lactic acid in the blood, and partly also by the oxidation of the lactic acid in the blood itself; and that from the increased oxidation in the tissue an excessive amount of uric acid is formed, which the liver is unable to act upon; it escapes into the blood unchanged, and is eliminated by the kidneys.

If the energy of the red blood-corpuscles was in any way diminished or inhibited, and there was no increased oxidation going on from lactic acid being present in the blood, but merely dilatation of the minute arteries, then if the vessels of the kidney were affected in the same way we should have simply increased flow of urine—diabetes insipidus. Again, in diabetes mellitus as there is no rise of temperature, and the glucose is not oxidised in the blood, is the energy or number of the red blood-corpuscles inhibited or modified?—and if the energy were unrestrained, would this give rise to hyperpyrexia? We know that during the progress of disease intercurrent with diabetes the sugar does sometimes disappear from the urine, but this may be only from the introduction of some zymotic element into the blood.

Is it possible, then, that altered intensity of the "coördinating chemical centre" presiding over the changes in the tissue and in the liver, and a variable energy in the action of the red blood-corpuscles, may express the pathological relationship between hyperpyrexia, diabetes mellitus, acute rheumatism, and diabetes insipidus?

(*To be concluded.*)

[9] Med. Chirur. Review, Jan. 1857, p. 42.

ON RICKETS.

BY JAMES F. GOODHART, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN TO GUY'S HOSPITAL, AND TO THE EVELINA HOSPITAL FOR CHILDREN.

AT the discussion on Rickets at the Pathological Society it was necessary to compress what I had to say into the last five minutes of an unusually long sitting, and to this was added the knowledge that the opener of the debate had still to occupy more time with his reply. Such conditions were conducive more to vigour than to precision of statement; some things that I wished to say had to be omitted, and others were too shortly put to make my full meaning intelligible. But though obscurely stated, the points themselves are not unimportant, and considering that so few facts have been added to our knowledge, I venture to put on paper in a more detailed manner what I should have said elsewhere had time permitted me, and while attention is still directed to the subject.

My text is visceral rickets, if there is such a thing. Three propositions concerning this branch of the subject have been put forward at one time or another.

1. That the spleen and liver are not enlarged in rickets—the seeming increase is due to displacement.
2. That the enlargement of the spleen and liver is as much a part of the disease as the changes in the bones—an opinion advanced by Sir Wm. Jenner and supported by Dr. Dickinson.
3. That the viscera are enlarged, but present no distinc-

tive features, and that the increase in size is due to some cause antecedent to it, and the skeletal changes—an opinion attributed to Dr. Gee and reaffirmed by Dr. Hilton Fagge.

I shall confine myself mostly to the question of splenic enlargement, because I think the facts at hand concerning the liver are hardly sufficient to enable us to form a positive opinion whether it is or is not diseased in rickets. To take the three statements in order—

1. Is the spleen enlarged, or is it not?

It is certainly enlarged in some cases of rickets—(*a*) by the unanswerable proof afforded by post-mortem examinations; (*b*) I have notes of cases in which the spleen has occupied a third at least of the abdominal cavity during life, an amount of enlargement which puts the possibility of a mere displacement in such quite out of the question; and (*c*) it is possible to separate during life those cases of rickets with splenic enlargement from those without it, almost without physical examination, by means of the peculiar pallor which the splenic cases present.

No further evidence is wanting to demonstrate that an actual increase in the size of the spleen is, at any rate, an occasional fact in the history of rickets.

Having stated that there is post-portem proof of splenic enlargement in rickets, I will next state what is the change which, I conceive, such spleens to have undergone—a point upon which there has been some difference of opinion, even in the late discussion. I have examined four cases; and, to judge from them, the spleen is large and firm, with some slight thickenings of its capsule; its section is homogeneous in appearance, from the paucity of the Malpighian corpuscles and the want of contrast which is usually afforded between them and the splenic pulp. Under the microscope the change is one of hyaline fibroid thickening of the septa and stroma at the expense of the pulp and Malpighian sheaths. I have described and figured this condition elsewhere,[1] so that it is unnecessary to say more of it here.

From this it will be seen that I am quite in accord with Dr. Dickinson, so far as the spleen is concerned, that the change is one of interstitial splenitis, if it be desirable to call it so, but perhaps better, of interstitial fibrosis, the new material being of a hyaline kind, and not necessarily, by any means, the outcome of an inflammatory state. I have not been able to detect any similar change in the liver; or, perhaps, to put this statement more guardedly, I have not been able to satisfy myself that this material exists in the rachitic liver in an abnormal quantity.

Sir Wm. Jenner alluded to some observations of his own, in which the spleen and liver in thin sections were found to be glue-like from the presence of a peculiar morbid deposit, appearances which he considered denoted something of an unusual kind, and he therefore takes exception to Dr. Dickinson's description of the change as one of interstitial fibrosis. But, if I may be allowed to say so, the observations of Sir Wm. Jenner are by no means irreconcilable with those of Dr. Dickinson. It will be allowed that the glue-like change must have been exceptionally extreme, and it is well known that this fibrous material, or hyaline fibroid, when it rises to an extreme degree, presents just such a gristly, cartilaginous, and in thin slices, glue-like appearance, as was noticed by Sir Wm. Jenner; and so far from any antagonism, we have, indeed, some remarkable facts in corroboration of the assertion that the disease is one of thickening of the stroma of certain organs. The orginal term—albuminoid—applied to this material is not by any means a bad one as applied to the morbid material itself; it is objectionable chiefly in that it has been taken to indicate something peculiar to the morbid deposit of rickets—a something not found in other diseases—whereas the material does not differ from that found in several other states, or, to speak more precisely, from the morbid material found in the spleen in chronic enlargement, from ague, and many other conditions.

When I come to the next question, What is the relation between splenic enlargement and rickets? I am no longer able to keep company with Dr. Dickinson, as I am unable to support his contention that the visceral enlargement is as much a part of the disease as are the skeletal changes. I am mostly influenced in thinking otherwise by finding that the splenic enlargement, in my experience, occurs in but a small proportion of cases of rachitis, and that when it does occur it is by no means in the worst cases. I am unable to say what number of cases of rickets have come under my notice, but, as is patent, they form a staple commodity in out-patient practice, and it is certainly a very moderate computation to say that in the last seven years I have seen 800 to 1000 cases, and it has always been my habit to examine for splenic enlargement, and all such cases have been carefully recorded. Referring to these notes I find fifty-three cases of splenic enlargement of all sorts. They are grouped as follows:—

Leucæmic	3
Rachitic (certainly)	16
Rachitic (doubtfully)	7
Cause unascertainable	14
From congenital syphilis	9
Tubercular...	5—54

One of these cases being both syphilitic and rachitic has been included under both heads, explaining the fifty-*four* total. Now, considering the difficulty which exists in distinguishing slight degrees of rickets, we may include the doubtfully rickety enlargements as rickets, and we have then twenty-three cases; we might even do more, and include those cases in which the enlargement was due to no very obvious cause—a matter of fourteen more, or thirty-seven all told. And they would still—although rachitic enlargements form the greater part of all the splenic cases—form so small a proportion of all the cases of rickets, as can hardly be said to indicate that the enlargement is as much a part of the disease as the changes in the bones. I have called no spleen enlarged which was not certainly palpable below the ribs, or if the chest was sufficiently distorted to explain its altered position.

It does not seem, therefore, that the swelling of the spleen can be in any sense essential to rickets, since it occurs so seldom; and I am disposed to agree with Dr. Gee and Dr. Hilton Fagge that when it occurs it is due to some cause which antedates both it and the bone enlargement.

It may, however, be said that this argument is much weakened by the fact of congenital syphilis, as shown in my own table. Congenital syphilis is very common in the out-patient room; and if we were to enumerate all the cases and estimate the proportion in which enlargement of the spleen occurs, it would be but a small one—smaller, I think, than that of enlargement of the spleen to rickets. I have notes of nine cases only. But though such a small percentage of all the cases, it is not contested that the splenic enlargement of syphilis is an integral part of the disease, as much as the other signs of the malady. This is all true; but then, on the other hand, there is this difference—the spleen in congenital syphilis, and the liver also, are known to present certain definite cell proliferations, which are similar to those in other parts, and similar to those of syphilis in the adult. This is not so in rickets. The change in the one may be said to be specific, in the other "indifferent."

The liver of rickets appears to be, from my notes, but seldom enlarged, and when it is the increase is, as Dr. Dickinson has already stated, inconsiderable.

Passing now to the blood and its condition in rickets, I have wondered that no one has hitherto drawn attention to it in this discussion until our President alluded to the absence of observations on the subject. I know not whether Mr. Hutchinson had in his mind a chemical or microscopical examination, or both. Both would be instructive, but a chemical examination of rachitic blood presents difficulties of achievement which I have not surmounted, and I can only speak of microscopical work. Some years ago I examined the blood of many rachitic children; the notes of these were scattered, and have unfortunately been mislaid, but I well remember that in many of them its condition was a very peculiar one, though it was not always the same. In some there was simple deficiency of corpuscles, in others deficiency of colouring matter; but in most these points were not so noticeable as the remarkable variety which the size of the red corpuscles exhibited. There were three, four, and five different sizes of red corpuscles, these going with a quantity of free granules; beaded strings and dumb-bell aggregations, such as have always been held to be morbid, but the exact significance of which is still doubtful. I have lately, for the purposes of this discussion, turned my attention again to this subject, and verified my former observations, though only in a few cases.

Whatever the significance of such changes may be it cannot be disputed that they may be of considerable importance, and they are in accord, I think, with the view expressed so clearly by Mr. Hutchinson, that rickets is a diet disease. I am quite in accord with such an hypothesis. Nor can I see any difficulties in the way of accepting it provisionally, except that it appears to be difficult to prove its truth. Children are either fed badly or assimilate badly; bad blood is formed, and bad bone follows. The microscopical appearances of the blood are such as to suggest both immaturity and poverty. These are conditions, no doubt, which might in part, according to present physiological doctrine, be due to an abnormal bone development. But, on the other hand, there is a certain amount of evidence, perhaps I ought to say a consensus of opinion rather than evidence, in favour of rickets being produced by bad feeding. Bad feeding or faulty assimilation must act primarily upon the blood, but not necessarily by producing always a constant deficiency of one particular element or excess of others. A general lack all round would, it seems to me, be the alteration which would best supply the conditions which I conceive to be necessary for the production of rickets. But this brings me to a departure from facts, to which I have hitherto attempted to keep myself, to enter upon a somewhat speculative subject—the relation between the cartilaginous changes and the spanæmia. And, first of all, I would dwell especially upon this, that the histology of rickets points to improper development more than to disease. Clinically, of course, rickets is a disease, but pathologically it is not so much disease as arrest or perversion of the developmental process, and I would venture to make this criticism upon the suggestion that has been made, that rickets mollities ossium and senile fragilitas ossium are similar processes, differing only in the age of the patient; that whereas rickets is a perverted development, those other states are degenerations of formed material, and one of them, senile fragilitas ossium, and perhaps the fragilitas ossium of mental incapacity, has some ill-defined relationship to cancer which we as yet know little of. Though all of these have certain striking features of resemblance, such as distortion of the bones, yet in their essence they are far asunder, and there is nothing in the softening bone of old age, that I can see, at all like the growth of cartilage that occurs in childhood in place of the normal growth of bone. It is a hazardous thing to attempt to say why or how any process takes place in the animal economy; but I cannot help suggesting that instead of considering rickets to be a disease we should look upon it as more a product of cultivation—a process allied to that which takes place when a gardener by particular soil essays to cultivate special parts of plants at the expense of the rest of the organism. Supposing we attempt to cultivate some flower or fern under conditions foreign to its habit, one of two things happens—unless it be so hardy that its range of accommodation is a wide one—in the process of acclimatisation it becomes starved, and dwindles, and dies; or certain abnormalities crop up which it may or may not be to our interest to try and perpetuate. And should we replace the dwarfed organism under natural conditions it speedily reverts to the old type. Is it not thus with the infant? An attempt is made to acclimatise it to conditions unnatural to its development; its juices suffer in the process, and in most cases the result is slow starvation and death. But in still a large number of cases this extreme is averted, and some of the parts become, as it were, naturalised. The lower, or least specialised, tissues stand the ordeal best; the highly specialised waste. Hence fat and connective tissue and cartilage seem to have it all their own way; muscle and bone languish. Put the child again under natural conditions, and in the great majority of cases the tissues revert to their normal habit, and the rachitis disappears completely. I take this to be proved by the fact that anything approaching to acute rickets, or, indeed, rickets of any sort, save its effects, is very uncommon after the age of six or eight. Have we any parallel case of a disease so severe as rickets, to judge from its distribution in the body, and affecting structures so important to young life as the bones, invariably getting well, if treated properly? I think not.

---

[1] New Sydenham Society: Atlas of Pathology, Fasciculus 2.

I would further remark that in cartilage we have to do with a peculiar tissue. It lives mostly by imbibition, and in one sense it is a coarse feeder, not very particular about quality so long as it is supplied with the requisite quantity. Witness the madder staining which can be practised upon it; the urate of soda it will tolerate with comparatively little reaction. It would seem to be more important for its well-being that it should have fluid than solids, as may readily be seen by the rapidity with which it shrinks to a mere relic when exposed to the atmosphere, and will regain its natural appearance by simply soaking in water. I can readily understand that material such as this will tolerate grave alterations in the fluids, and yet continue to thrive in some sense, nay, even to overgrow in the dropsical manner of the rachitic overgrowth, while the muscles are pale and tender from the badness of the supplies, and while all other parts are stunted and poor.

The changes in the viscera are not inconsistent with this view. An altered blood means for the tissues altered blood pressure, and this again implies considerable disturbance to the circulation in various localities with consequent changes in the tissues outside—congestion, œdema, &c., are the natural consequences. And, if we further remember the close relationship which exists between blood changes and splenic, perhaps also hepatic, enlargement, there is no lack of material to explain the occasional occurrence of swelling of these viscera in rickets.

Nor do I think that such experiments as those given to us by Dr. Baxter tell against what I have here put forward. For although conducted, as they would certainly be by so shrewd and cautious an observer, with the greatest precision attainable, they are, they cannot be otherwise than, rough handed, when compared with the slow process of modification which goes on in the fluids of the infant under the many modes of artificial feeding adopted in this country, and protected as the system is in a measure by the obvious fact that what does not please—that is, is not suitable to, an infant's stomach—will be rejected. I do not doubt that an infant's stomach has, so to speak, a blind eye, but I do doubt whether many of the harmful compounds administered to it find this out, and enter the circulating fluids. And for this reason, because I believe it to be almost, if not quite, impossible so to direct the means sufficiently insidiously and persistently to the end aimed at—to be impossible, in fact, to perform any experiment which shall fulfil the required conditions—I dissent altogether from the doctrine of my colleague Mr. Lucas, that rickets can be induced with certainty by artificial feeding. The experiment is performed for us unconsciously in hundreds of cases by mothers with their children, and with a like result to that of Dr. Baxter with his puppies, the botanist with his ferns, of starvation, wasting, and death. But rickets can only be produced by a very slow process of careful cultivation, and provided that the gastric apparatus can be made to work subserviently to such an end. I see no reason with regard to animals why we should expect to produce rickets at all. Is not the rickets of animals expressed in the light porous periostitis-like bone which is to be found in most museums as a common disease of the lower animals.

I can only allude to other points very shortly. And, first, as to fœtal rickets. It appears to be assumed that if once fœtal rickets is proved to have an existence the diet disease hypothesis is no longer tenable. But does this follow? Why should the fœtus be exempted altogether from diet diseases? It obtains its food, it is true, already assimilated as blood; but if a carefully adjusted and gradually adapted badness of blood be the cause of rickets, such a cause must surely operate sometimes in the fœtus. I would rather hold to the opposite opinion—that, if it can be shown that fœtal rickets has not even an occasional existence, a strong blow is thereby given to the diet disease hypothesis.

The next question I would ask is this, Is rickets only to be produced by one cause or set of conditions? I ask this because it seems again to be assumed that if the condition can be shown to be associated with cretinism it is no longer rickets. I am not prepared to admit this. I have elsewhere attempted to show[2] that arrested development of the brain is a condition which favours excessive growth of the least specialised tissues, connective tissue (subcutaneous) and fat more particularly, but possibly cartilage also. From what I have seen of the cretin condition, particularly in a specimen lately presented to the College of Surgeons by Dr. Hermann, it seems to be an exaggerated rickets. The bones are all ends. The cartilaginous ends are exceedingly large; the shafts unusually small. Is it not possible that this may prove to be a similar condition to that which we call rickets, though owning an entirely distinct origin?

The strongest argument against the view here taken of the nature of rickets may, I think, be derived from the fact that the disease is so little prevalent in other countries that it has received the name of the English disease; yet I find it difficult to suppose, as does Dr. Baxter, that artificial feeding is so very different, in the United States for example, from what it is here. I am not prepared to combat fully an objection of this kind at the present time, but I may just remind the reader that it has been one of my objects in the present paper to show that artificial feeding can only produce rickets under certain conditions, which may well be absent either in whole or part in other countries.

Weymouth-street, W.

THE SIMULATION OF SOMNAMBULISM.

By CHARLES RICHET, M.D. PARIS.

(Concluded from p. 9.)

ANALGESIA and anæsthesia are very often exhibited by somnambulists. These two phenomena are constant, or nearly so. It is now the fashion to say that the anæsthesia is due to simulation. Certainly, in considering the matter in a general way, insensibility may be feigned. But how many persons are there who would have the courage to bear without serious reason pricks on the face, on the nostrils, or hands; to allow their hair to be plucked out, and the conjunctiva, the nose, and the ears to be tickled; to have pins thrust into the arms; to drink nauseous liquids; to breathe with delight ammonia or sulphurous acid? Such are the tortures they would endure for the sole pleasure of duping the simple physician, who looks curiously on and takes notes. Nearly all somnambulists behave thus. They oppose no resistance to every test; they do not push them away, nor tremble, remaining impassive and vacant, braving without moving a muscle tests as disinterested as they are painful. Must we suppose that they exhibit heroism (and a very misplaced heroism) or anæsthesia?

I could multiply examples to prove how absurd is the hypothesis of simulation. Thus, nothing but the fact of being able to vomit at will indicates, indeed, that there is a psychical state different from the normal. Who is there who could vomit because one said to him, "What a bad smell!" It is, however, a constant phenomenon with the somnambulised; and to provoke the vomiting there is no need of a more complicated method. A somnambulist weeps when told to weep, sheds a flood of tears, and loudly sobs. Can we believe that it is easy to weep at will? Make the experiment on oneself, and see how impossible it is. *Amicus noster quidem quem ad somnitationem facile suscitamamus, si de libidinosis rebus loquor, statim it erectionem. Si jubemus ut mingat, mingit; et restem fœdat.*

I recently witnessed an accident which might have been very grave, but which fortunately had no serious consequence. It was in the case of a young woman who will be frequently referred to in the course of this article, and who is an excellent magnetic subject. Wishing to excite fright in her. I said to her, "See, I take your arm, and I cut it. Look at the blood flowing." Immediately, without a cry or a gesture, she fell flat down on the ground, as if dead. In fact, life had ceased temporarily. The heart no longer beat, there was no respiratory movement; this state lasted for about half a minute—a century of anguish for me—then a deep respiration told of the return of vital phenomena. Perhaps it will be said, this syncope was only a clever piece of acting? However, at the risk of being thought to be very simple, I should not wish to try this experiment again at any price.

We may then, it seems, if not find an absolute or irrefutable proof, at least accumulate very convincing proofs to demonstrate that there is a somnambulistic condition. Let us now examine the objections opposed to it. The following are, if I am not mistaken, the chief :—

First objection.—The phenomena of somnambulism are incompatible with the facts of science. It is impossible to admit the "pass" can produce sleep, that a fluid escapes from the body at the will of the magnetiser, that thought is transmitted without an external manifestation, that vision is performed by the epigastrium, audition by the palm of the hand, and perception of taste by the forehead. It is easy to make answer: Somnambulism—this neurosis, whose causes and nature are still so mysterious—has nothing to do with the explanations attempted to account for it by charlatans. It is not a question of declining to refute their more or less interested vagaries, but of studying and verifying what has been seen by serious *savants* worthy of respect. All those who, instead of applying themselves to prove the inanity of the miracles performed by the somnambulised, have tried to see for themselves, have soon been convinced that by the influence of "passes," or by the "fixed gaze," there is produced a special neurosis, with well determined characteristics. It is easy to deny such or such grotesque tales, but what will they prove except that there are dupes and rogues mixed up in this problem of pathological physiology? It would seem, in view of so many widespread errors, that a number of truths must be found mingled with them. If it were all phantasmagory or simulation not only would magnetism not have been established, but it would not have been promulgated, and would have disappeared without leaving a trace behind. Error can only triumph by reason of the truth it enshrines.

Besides, we have not such perfect and precise notions on the nature and functions of the nervous system that we can deny the possibility of such or such a phenomenon. The experimental method should always guide us, and *à priori* denials ought, like *à priori* affirmations, to be banished from scientific discussions. In truth, as regards somnambulism, the denials have always been *à priori.* I do not believe that an experimenter, supported by a sufficient number of facts, has come to the conclusion that somnambulism is not a fact. The denial has to be supported by reasoning, and not by experiment. No one yet, to my knowledge, has been able to say, "I have tried to hypnotise four persons, at different times, by employing the usual procedure, and I have obtained no result." So far, people have been contented to smile, and to say, "It is impossible." Such a refutation seems to me insufficient.

Second objection.—Everything observed is inconstant, irregular, mobile.[1] No fixed rule, the phenomena observed varying with every observer, and with each subject. What is predicted is not produced, and what is not predicted is produced. This objection is based on a real fact. Indeed, the first time that an individual is hypnotised, she finds herself in a special condition, which requires a real education. According as the experimenter desires to provoke this or that phenomenon, he will be able to direct the attention of the subject to it, and to act so that this phenomenon is produced. That simply means that will, habit, and education play an important part in the manifestations of the somnambulic neurosis. But this vague and unconscious influence cannot be regarded as simulation. When a lunatic reasons, reflects, meditates, he often shows evidence of much logic. Will it be said that he is not mad? Only people who know nothing of medicine would think so. In fact, a lunatic and a somnambulist reason, reflect, meditate, and it would be absurd therefore to conclude that they are simulating.

There are often seen certain strange psychological phenomena which it is necessary to know. Some hypnotised subjects regard their hallucinations as fictions, and say that what they see before them, with forms apparently real, is not reality. This is observed in dreaming, and also in insanity. We often dream of monsters so strange and visions so absurd that we cannot believe them. There occurs also a sort of doubling of consciousness; we dream and we know that we are dealing with a dream, and we make great efforts to drive away the vision which oppresses us. So do those who have hallucinations hear voices which they very well know to be subjective. So also certain somnambulists are conscious of their state, and thus a curious antagonism is set up in them. Their imagination shows them the real form of things, and their intelligence understands their absurdity. That is why they often exhibit contradictions, which, to a superficial observer, would seem to reveal simulation. The fact was very striking with a patient at Beaujon, quite a young girl, whom I hypnotised on several occasions with the greatest facility. I told her that I was going to perform a painful operation on her—amputation of the arm, for example. She cried out with pain, wept abundantly, and thought she saw the blood flow; but almost at the same moment she understood it was a fiction, and laughed through her tears. Often also, when one makes imaginary voyages with hypnotised subjects, they know full well they are on their own couch or in their bed, and yet they see the regions where we have had the fancy to lead them; just as in ordinary sleep, we find ourselves transported into far off countries, without forgetting, however, that we are tranquilly asleep in our own room.

---

[1] In an article in *The Times*, where a paper I contributed to the *Revue des Deux Mondes*, on "Demoniacs, Past and Present," is analysed, I am thus laid open to reproach, it being objected that it is impossible to describe the changing and fugitive phenomena of hysteria. As much, said the critic, might one try to fix on a photographic plate the mobile surface of the ocean. Now, this observation, which appears to me to be of slight foundation, and little justified by fact, is joined by another reproach quite as singular; it is that things are spoken of which we ought to be silent about; that we provoke, by the description of hysteria, attacks of this disease; that we contribute, in a word, not to the knowledge, but to the extension of the disease. Surely this is scientific prudery!

However seldom one may have been present with some case at the gymnastic performances which the professed magnetisers present to the public, one is convinced, on the one hand, that the *subjects* are, indeed, hypnotised; on the other hand, that they also practise trickeries. There are somnambulists who simulate. These two terms are not contradictory, as might be wrongly supposed. In fact, a hypnotised woman does not so far differ from the condition of her waking state that she cannot understand her situation, reflect, and simulate. She is hypnotised, as all the physiological phenomena she presents show (catalepsy, contraction, anæsthesia, fibrillar movement of the eyelids, movements of the eyes, suppression of movements of deglutition). But whilst being indeed asleep she plays her part—tries to divine the future; to read distinctly in the body of the patients who consult her; to divine, by a lock of hair, the age, the character, or the health of anybody. These divinations form part of her trade. She knows it, and conforms to it. She is, however, really asleep, and it is, indeed, owing to somnambulism that she can perform all these practices. If she were awakened she would be forced to expend prodigious mental activity, and to support unbearable muscular fatigue. We have seen *imbeciles* simulate madness, just as there are somnambulists (really hypnotised) who simulate lucid sleep. It would require prodigies of dexterity, and the muscular force of an athlete, to go through half the astonishing exercises which a somnambulist can easily perform, thanks to the cataleptic state of her muscles. The famous Lucile, whom everyone saw at Paris, two or three years ago was really hypnotised. But, although hypnotised, she well knew that she was on the stage playing her part before the public, and succeeded in her tricks with the regularity of an actress who plies her profession honestly.

All these characters—diversity, inconstancy, irregularity—are perfectly explained by the prodigious complexity of the phenomena of that mystery—the mind. The brain is a mechanism a thousand times more complex than a flute, and yet an ignorant person could not play on this instrument if he had not previously learnt how to handle it. "You would play upon me," says Hamlet to the emissary of the king, his uncle—"you would seem to know my stops; you would pluck out the heart of my mystery; you would sound me from my lowest note to the top of my compass; and there is much music, excellent voice, in this little organ; yet cannot you make it speak? 'Sblood, do you think I am easier to be played on than a pipe?"

These words of Hamlet may be addressed to those who find the psychical phenomena of somnambulism too inconstant to be scientific. Suppose fifty inexperienced individuals attempting to play the same air on the same flute; they only elicit discordant and rude sounds in fifty different times. Why, then, be astonished that physicians or observers, all very ignorant of the intimate nature of the nervous system, only obtain contradictory results? To my thinking it is more surprising that, in spite of our profound ignorance, in spite of the almost infinite diversity of the experimental conditions, there is yet so much analogy between the phenomena observed. We ought to be really struck by the resemblances rather than the differences, for the latter are of small account relatively to what they might be. For my part, proceeding always in the same manner, I have invariably obtained sufficiently concordant results, in spite of the enormous differences in the subjects submitted to experiment.

The differing aspects of the same disease are sometimes more marked than the different aspects of somnambulism. Besides, why not compare it to a disease? It has a period of onset, a stationary period, and a critical period, constant fundamental symptoms, and accessory or inconstant symptoms. It always resembles itself.

To sum up, it can be proved that somnambulism is a real fact, if not by an absolute proof, at least by the whole of the proofs which plainly demonstrate that the hypothesis of simulation is absurd. Scientific scepticism is an excellent method, but it must not be pushed to the point that everything is either illusion or deception. To admit that hundreds of observers, ordinarily sagacious and reserved, have allowed themselves to be deceived by mystifications, that these mystifications are being incessantly practised, bringing no gain but unbearable vexation to those who play with them, and to suppose that this pleasantry may be repeated, without modification, for a century, in most diverse countries, is to fall into an excess of prudence. For every man who has examined the question it is as absurd to doubt the reality of somnambulism as the reality of epilepsy. After all, if there are still people who hesitate, let them see for themselves, let them study, let them experiment, they will soon be convinced that their doubt is not justified, so clear and striking are the facts, so much do they overcome all hesitation by their greater force.

CASE OF STRYCHNINE POISONING TREATED SUCCESSFULLY WITH BROMIDE OF POTASSIUM AND CHLORAL.

By ENGLEDUE PRIDEAUX, L.R.C.P. LOND., M.R.C.S. ENG.

THE following case occurred some years ago, but for obvious reasons I have been unable to send it for publication until the present time. The facts of the case are as follows:—

At an institution with which I was connected there was a stock mixture kept, containing bicarbonate of soda 10 grs., carbonate of ammonia 3 grs., ammonio-citrate of iron 5 grs., and solution of strychnia 5 minims, in an ounce of water. This mixture was frequently ordered for out-patients in cases of atonic dyspepsia.

One morning, after seeing the out-patients, I happened to walk into the dispensary and sat down at the dispenser's desk, he having gone out; whilst writing some memoranda my eye was caught by a pencil statement on the blotting paper of a calculation of the contents of the stock bottle containing the mixture of citrate of iron and strychnia, and I noticed that in jotting down the whole amount of each constituent the dispenser had substituted ounces for drachms of the solution of strychnia. I sent for the dispenser at once, and on tasting the contents of the stock bottle it was evident that the mistake had been made, and three lots of about half a pint each had been given out. The dispenser explained that whilst giving out the medicines the stock bottle ran short, and he proceeded to refill it, making it up whilst a number of patients were waiting, and in his hurry the mistake occurred. After taxing our memories as to which patients were taking the mixture, we were able to find out the new ones, but not all those to whom it had been repeated. We went to the addresses of all we could find, and under some pretext got the medicine back, but after all it was evident that one, perhaps two, still remained, and these we were unable to trace.

Finding there was no help for it I set to work, so as to be prepared, and remained in-doors all day. After much consideration and consulting the books I had, I resolved to rely upon bromide of potassium and chloral, as being the drugs which in their action were most antagonistic to strychnia. I therefore prepared some strong solutions and waited events.

About ten o'clock a message came to ask me to go and see Mrs. C——, who was having very bad fits. I at once put the remedies in my pocket, with a bottle of chloroform, and, accompanied by a medical friend to whom I had related the circumstances, started off to the address of Mrs. C——, whom I at once recollected as a patient who had been taking the citrate of iron and strychnia mixture.

From the person who came (a half-witted woman, the sister of the patient) I learnt that Mrs. C—— had been out at work in the open air all day, and coming home between five and six had her tea, and some time after tea took a good dose of medicine; in the evening, while standing at the door of the place she lived in, she fell down in a fit and had had them ever since, and was then said to be dying. The messenger had been to a doctor in her neighbourhood, who had refused to go. She was much excited when she came for me, and declared her sister had been poisoned. As far as I could gather, some two or three hours or more had elapsed from the time her sister had taken the medicine to the time she was taken ill, and the fits had been increasing in frequency and strength during the past hour.

On arriving at the house I found the patient, a woman of about fifty years of age, lying on a mattress upon the floor, unable to speak and perfectly rigid, and in a condition of constantly recurring opisthotonos, the convulsions succeeding one another with great rapidity, with all the appearances of acute strychnia poisoning. The pulse was slightly quickened, but otherwise fair. As soon as the jaws were relaxed, I administered half an ounce of bromide of potassium in solution with one drachm of chloral. After a quarter of an hour the spasms began to materially abate, and the muscles relaxed in a marked degree. I then administered another half ounce of bromide in solution, and in half an hour there was almost perfect relaxation, with slight spasms recurring at much longer intervals. After remaining with the patient for some time, and finding the spasms did not recur in their intensity, but were becoming much slighter, and only occasional, we left, leaving another ounce of bromide to be given in divided doses of two drachms every four hours during the night. We were shown also an old wineglass, with the foot broken off, and told that she had poured out the medicine into this without measuring it, taking nearly or about a full glass, as she said to them "To make up for not taking any during the day." I took away the glass, and afterwards found it contained a full two ounces and a half.

The next day I visited the patient early in the morning, anxious to know the progress of the case. I found her in a very feeble state, and to my surprise quite unable to raise herself, and able hardly to move a muscle; indeed, she seemed like a sheet of wet blotting-paper, and was almost completely paralysed; her water had run away in great excess, and a large quantity of liquid fæces. Her pulse was slow and markedly feeble. She had taken half of the quantity of bromide left. I stopped its administration, and ordered strong beef-tea and milk with a little brandy at frequent intervals. On the evening of the same day there was little alteration.

From this time she progressed towards convalescence very slowly and gradually, her recovery being much retarded owing to the inability of her friends to obtain sufficient and proper nourishment. After three days she was able to raise herself, and had regained power over the sphincters, and on the fifth day was able to sit up. She was then removed to the union house, where she rapidly recovered.

The woman must have taken, from the size of the glass she used, fully two ounces of the wrong mixture, each ounce containing forty minims of liq. strychniæ, P.B.—that is, eighty minims in all, nearly three-quarters of a grain of strychnia. I have not been able to find any record of the administration of so large a dose of bromide of potassium, but it appeared to me necessary to give as large a dose as possible, inasmuch as the poison had been in the stomach for a considerable time, and it had all, or nearly all, been absorbed. The symptoms had been increasing in severity, and from their intensity were evidently attaining their maximum, and must have soon produced death by interference with the function of respiration, so that to give smaller divided doses would have been useless. The effect of the first dose was remarkably complete, temporary muscular relaxation occurring in about twenty minutes, and the succeeding convulsions becoming rapidly altered in character.

I believe that the complete muscular paralysis which occurred, and was so slowly recovered from, was owing to the partial abolition of the functions of the spinal cord, caused by the exhibition of the remedy, and was not due to nerve or muscular exhaustion consequent upon the extreme excitation and activity induced by the poison.

Wellington, Somerset.

LIFEBOAT SERVICES IN 1880.—A list of the services rendered to shipwrecked crews by the lifeboats of the National Institution during the storms of the year which has just closed, shows a total of 577 lives and 27 vessels saved from destruction. In the same period the Lifeboat Institution granted rewards for saving 120 lives by fishing and other boats, making a total of 697 lives saved. Since its formation the society has contributed to the rescue of 27,600 shipwrecked persons.

CASE OF RECURRENT PEMPHIGUS PRURIGINOSUS FOLLOWING CHECKING OF THE MENSES.

BY W. A. DUNCAN, M.D.

MISS B——, aged twenty-five, has always had good health. First began to menstruate when fourteen and a half years old; since then "the periods" have appeared regularly every month.

On July 28th, whilst out walking, was caught in a storm and got wet through; the same night she felt chilly and languid.

Next morning (29th) patient noticed that the menses, which had commenced the previous day, were stopped. She now complained of headache, nausea, and general malaise, together with a peculiar tingling sensation in both hands. These symptoms continued till August 1st, when I perceived numerous small round papules on the palmar aspects of both hands, and also on the sides of all the fingers. The hands were somewhat swollen and slightly œdematous, but the skin was not inflamed. The sensation of pricking and tension was so great that the patient could obtain no sleep without the aid of a morphia draught. A saline mixture was ordered every three hours, and a lead lotion (1 in 20) to be kept constantly applied to the affected parts.

On Aug. 2nd the papules had developed into vesicles, which, in irregular groups, were situated most accurately over the course of the median and ulnar nerves on the palms and fingers; even the small palmar cutaneous branches of both these nerves over the anterior annular ligaments had their appropriate vesicles. The swelling and œdema were more marked, and there was intense irritation and pricking.

Next day (Aug. 3rd) the vesicles along the sides of the fingers had developed into round bullæ, from a quarter of an inch to half an inch in diameter, and from their size they caused the fingers to become widely separated. On pricking these bullæ decided relief was obtained, and a perfectly clear, colourless fluid escaped; in some, however, the contents, though perfectly transparent, were of more consistence, as only a slight amount of fluid followed the puncture. On the palms the bullæ were much less developed, the largest being about the size of a pea, and the patient complained of great pain in them. "As if the palms would burst," she said. The lead lotion was therefore discontinued, and both hands were ordered to be enveloped in large bread poultices, and the morphia draught to be repeated if necessary.

Aug. 4.—Patient passed a better night; did not require the draught. The feeling of tension is much relieved, doubtless due to the poultices softening the epidermis. The bullæ on palms more developed, and several were punctured to allow the fluid (which was in each one colourless) to escape. The swelling and œdema still considerable. To continue poultices.

8th.—Patient expresses herself as altogether better, though there is still great irritation of the hands. Ordered to take a mixture containing bromide of potassium and liquid extract of bark thrice daily, to discontinue poultices, and apply constantly a lead and belladonna lotion; daily carriage exercise was also enjoined. Under this treatment the irritation and swelling gradually subsided, and on the 14th the hands and fingers were of natural size, and the skin was peeling off.

18th.—Palmar surface of both hands and fingers now denuded of old skin, exposing the new epidermis of a reddish colour, which itches excessively. The parts were ordered to be painted with a lotion consisting of equal parts of glycerole of lead and vaseline.

23rd.—Patient altogether better. Very little irritation.

25th.—Menstruating.

27th.—Although every possible care was taken to avoid catching cold, "the period" again stopped suddenly last evening; and on my visit to-day the patient (after passing a restless night) is not so well. Several papules appear on the sides of the fingers, and a few on the palms. The swelling and irritation are not so severe as on the first attack. Ordered an effervescing saline mixture, and the lead and belladonna lotion.

The further progress of this case is briefly as follows:—

Bullæ again developed, but not so large nor so numerous, and they gradually dried up under the use of the lotion.

On Sept. 1st I advised patient to go to the seaside in order to recruit her health before the next period.

Sept. 20th.—Just returned from Boulogne, where she has been since the 3rd. Feels quite strong. Hands are much better, but still continue to itch a good deal.

Oct. 18th.—Continues well, with the exception of some irritation of the hands, the skin of which is harsh and dry. No bullæ appeared at the last period, but the hands became hot and painful. Has been taking a citrate of iron mixture, with phosphorus and zinc pills, for several weeks.

This case is very interesting from several points: 1st, etiology; 2nd, character and recurrence of the eruption; 3rd, treatment adopted.

(*a*) With regard to pemphigus, Tilbury Fox, in his work on Skin Diseases, says its causation is involved in obscurity. In this case, however, the chill, which resulted in checking the menses, evidently was the cause; but how this acted I am not quite prepared to say, unless by causing general disturbance of the nervous system, and especially the terminal distribution of the median and ulnar nerves, thus producing localised changes in the vaso-motor supply to the affected parts.

(*b*) The symmetrical character of the eruption was well marked, and at first the case seemed to me to be a rare one of symmetrical herpes. However, the formation of bullæ on the second day showed I was mistaken. Tilbury Fox mentions two cases[1] he had seen in which the eruption was more or less symmetrical, and which he described as partly herpetic and partly pemphigoid. That the eruption recurred when the menses were again suddenly checked shows that the two stand in relation to one another as cause and effect.

(*c*) With regard to treatment, constitutionally it has been of a tonic nature. Unfortunately my patient is one of those individuals whose idiosyncrasy prevents them taking either quinine or arsenic. Locally, the greatest relief was obtained by the application of poultices, and afterwards of the lotion of glycerole of lead and vaseline. However, I am bound to say that, although much diminished, the irritation still continues to cause a good deal of annoyance, but this will most probably disappear after some further treatment.

Nov. 15th.—Since writing the above remarks the patient has continued to improve, and is now perfectly well. Under the use of the vaseline ointment all irritation of the hands has disappeared; the skin is of its natural appearance, and her monthly "period," which has just passed, was quite normal.

KING'S COLLEGE HOSPITAL.

FRACTURE OF THE INTERNAL CONDYLE OF THE HUMERUS; DISEASE OF THE JOINT; EXCISION.

(Under the care of Mr. Henry Smith.)

For the following notes we are indebted to Mr. S. Farmer, house-surgeon.

George K——, aged eighteen, was admitted into Fisk ward on November 11th, 1880. Ten days before admission he struck his left elbow against a piece of wood. This blow was followed by severe pain, which soon abated somewhat, so that he was able to follow his occupation for one day after the accident. He was, however, never free from pain, and in consequence of its increasing severity he was obliged to cease working. On November 4th (three days after the accident), linseed-meal poultices were applied and continued up to the time of admission.

On admission the patient was an ill-developed boy, and on inquiry it was ascertained that he was a seven months' child. He had always been unhealthy, and he had a scrofulous abscess in the left submaxillary region. The right upper limb was found to be swollen from the middle of the arm to the middle of the forearm. It was likewise hot, œdematous, painful, and very tender, the tenderness being most marked over the internal condyle. No fluctuation could be detected, nor was there pain on pressing the joint surfaces together. Temperature 101°; pulse 100. An angular splint was put on and ice was applied over the elbow, and a draught of ten drops of tincture of opium was given. A quinine and iron mixture and cod-liver oil were also ordered.

On the 12th the arm was still extremely painful, the ice having failed to give any relief. Hot fomentations were applied and the pain was relieved. In the morning the temperature was 99·3°; evening temperature 101·1°. On the 13th the pain and tenderness were less and the swelling had decreased. Morning temperature 98·2°; evening temperature 98·4°. On the 10th the pain was entirely gone, but the swelling still remained. He could move the joint slightly, but extreme movements gave great pain. Morning temperature 99·1°; evening temperature 100·2°. On the 19th the pain had again returned. The arm remained in nearly the same condition until Dec. 10th: there was no pain except on pressing over the joint. The swelling never disappeared. The general symptoms during this time were of a hectic character, with evening rises of temperature of from 1° to 2°; morning temperature varied from 98° to 98·3°; evening temperature varied from 99·2° to 100·4°. A fluctuating swelling could be felt on the posterior surface of the arm, two inches above the joint; and on the 11th the abscess was opened antiseptically; about half an ounce of pus escaped; dead bone could be felt at the posterior surface of the internal condyle. A large drainage-tube, two inches in length, was introduced. Morning temperature 99°; evening temperature 98·3°.

On the 16th the arm was very painful; morning temperature 100°; evening temperature 102°. And on the following day, though the arm was less painful, there was very free discharge. Morning temperature 100°; evening temperature 102·4°. It was decided to excise the joint. Accordingly, on the 18th, ether was given, and Mr. Henry Smith excised the joint in the usual manner. On opening into the joint the cartilages were found to be healthy. The internal condyle was diseased, and had been fractured. A sequestrum of bone the size of an almond was found above the trochlear surface of the humerus. The cartilage over the trochlear surface was detached, but was not diseased. The whole of the synovial membrane was thickened and diseased. All the articular surfaces were removed. There was free hæmorrhage, owing to the vascularity of the parts. A drainage-tube five inches long was passed between the ends of the bones. The operation was done antiseptically. The arm was laid on a cushion after the operation, and no splint was applied. Morning temperature 101·2°; evening temperature 98·2°. He passed a good night, but next morning the face was flushed, and the skin was hot and dry. The arm was dressed, and there was very free discharge. There was some tension. Morning temperature 103°; pulse 100. Evening temperature 103·1°; pulse 104. On the 20th the arm was dressed. The wound had healed by first intention, except at entrance and exit of drainage-tube. Morning temperature 99·2°; evening temperature 99·1°. On the 21st the discharge was much less. Morning temperature 98·1°; evening temperature 98·2°.

The boy has continued to improve. He has no pain; the temperature remains normal. He still remains under observation in the hospital, and has every prospect of recovering a useful arm.

ST. MARY'S HOSPITAL, MANCHESTER.

CASE OF PARALYSIS OF RIGHT LOWER EXTREMITY, FOLLOWING AN INJURY TO THE SACRAL PLEXUS DURING A DIFFICULT LABOUR.

(Under the care of Dr. Lloyd Roberts.)

For the following notes we are indebted to Dr. Walter.

A woman, aged twenty-eight, was admitted on Dec. 15th, 1879, suffering from wasting and loss of power of the right lower extremity. Her ailment dated back to her second confinement, which took place seven weeks previous to her coming into hospital. It was stated by the medical attendant that the labour lasted twelve hours, and that during the last three hours the pains, though very strong and frequent, were quite ineffectual in producing any advance of the presenting part, the head remaining during that time engaged in the pelvic brim. The forceps were then applied, and delivery accomplished with much difficulty. The child was large and stillborn. No anæsthetic was used, and the patient complained during delivery of violent pain and cramp in her right thigh, which continued without intermission until the child was born.

---

[1] Skin Diseases, rd ed., p. 221.

Next morning her leg and foot were "cold" and "numb," and there was complete loss of motion throughout the whole limb. This condition remained unaltered until the seventh day, when the patient again experienced the most intense pain along the course of the sciatic nerve; two days later slight swelling of the ankle and dorsum of the foot took place, the numbness and loss of sensation disappearing almost simultaneously, though the loss of motion continued complete.

During the seven weeks that elapsed before the patient was admitted into the hospital, she was unable to leave her bed, and at the time of admission the condition of the limb was as follows:—Well-marked wasting of the entire leg and thigh, the muscles of the calf being most atrophied, then those of the hamstring muscles, and, to a lesser degree, the gluteus maximus. There was slight œdema of the ankle, and the foot hung loosely, with the toes pointing forwards and downwards. Abduction and adduction of the foot were impossible, and flexion on the ankle-joint was very imperfectly accomplished. No movement of the leg could be performed. Cutaneous sensibility of the limb was normal, excepting over a small area in front of the ankle, where the œdema existed, and where also the patient complained of much pain. The muscles of the limb responded to the electric current less readily than those of the opposite side. Reflex movements were impaired, but there was no paralysis of bladder or rectum. The patient remained in the hospital a month, and had then recovered so far as to be able to walk across the ward, with assistance.

The treatment adopted was friction and shampooing of the limb, with the daily application of the electric current.

After she was made an out-patient she attended the hospital three days a week to be faradised. At the end of six months the paralysis had completely disappeared, and the patient was in excellent health.

Remarks.—The completeness of the paralysis that existed in this case warrants the supposition that considerable damage to the nerve trunk had taken place; fortunately these changes were not permanent, and as soon as the inflammatory products were absorbed the functions of the nerve returned, and the recovery was no doubt accelerated by the prolonged and steady use of the electric current.

The clinical history affords a well-marked example of paralysis from compression, and illustrates forcibly how hopeful prognosis may be in those forms of paralysis where the lesion is peripheral.

GENERAL HOSPITAL, SHANGHAI.

MULTIPLE LIVER ABSCESS IN CONNEXION WITH DYSENTERY; DEATH; REMARKS.

(Under the care of Dr. EDWARD HENDERSON.)

C. B——, a German, aged twenty-four, resident for several years in Hongkong and Shanghai, was admitted on the 24th of September, having been ill for two weeks, and suffering from "dysentery." He was thin, having, he said, lost flesh greatly since the beginning of his illness. He was very anæmic. He had had no rigors at any time during his illness, and had not experienced any well-marked pain in the region of the liver. There were slight jaundice and great prostration, with a peculiar odour of body and breath suggestive of general blood-poisoning. The pulse was 94, weak; the temperature on admission (afternoon) 101° Fahr. There was flatulent distension of the bowels, with general abdominal tenderness, the right hypochondrium and right iliac region being especially sensitive and resistant. The liver was apparently enlarged; in the right nipple-line comparative dulness began on the fifth rib and extended to a point half an inch below the costal margin, measuring in all six and a quarter inches. There was absolute dulness on the sixth rib, an inch and a quarter lower down. No friction sounds were audible in or near this area. The splenic dulness was normal; the urine was slightly albuminous. During the six days which followed admission the condition was briefly as follows:—General weakness progressively increasing; pulse weak, varying between 94 and 120; temperature very irregular, varying between 98·4° and 102°; no rigors; sweating at times profuse. No cough or vomiting. Motions averaging six in twenty-four hours, of the consistence of gruel, yellow-ochre in colour, slimy, not specially offensive, and not apparently containing blood. By the 30th of September the area of dulness in the right nipple-line had increased by at least half an inch, but the intercostal hollows remained unaltered; no distended vein had appeared on the surface, and no friction sounds were to be heard. At this time it was thought proper to aspirate the liver, though the symptoms rather indicated the multiple abscesses of pyæmia than the presence of a single (tropical) abscess. Three punctures were made—viz., in the right nipple-line between the sixth and seventh ribs; in the anterior axillary line between the seventh and eighth ribs; below the costal margin (in an upward direction) near the anterior extremity of the ninth rib. No pus flowed into the receiver by any of these punctures while the needle remained imbedded in the tissues, but about half a teaspoonful of thick pus mixed with blood was sucked into the bottle when air entered the instrument as the needle was withdrawn; the point of the needle did not at any time feel free as if lying in a cavity. The patient's general condition seemed to be somewhat improved on the following day, but after that he sank gradually, and died on the fourth, expressing himself to the last as free from localised or special pain. The diagnosis was dysenteric ulceration of the bowel, with multiple hepatic abscess, the post-mortem examination confirming this. The liver was moderately and uniformly enlarged, and its substance studded with abscesses in all stages of development, and varying in size from the dimensions of a pea to that of a large walnut. No abscess was found elsewhere in the body. The under surface of the liver, especially along its anterior margin, was firmly adherent to the peritoneal investments of the viscera in its neighbourhood, but only a few apparently recent adhesions had formed between the lower surface and the parietes; these last were in the axillary region. The great gut was deeply and extensively ulcerated, but only one small superficial (catarrhal) ulcer was found in the small intestine.

Remarks by Dr. HENDERSON. — Cases of this kind are rare in Shanghai, the usual liver lesion in connexion with bowel ulceration being the single, so-called tropical, abscess. It is of importance to note the significance of the "typhoid state" in connexion with diarrhœa and dysentery in the East. Should this condition be developed early in the history of a case, my observations lead me to suspect either sloughing of a large tract of the mucous membrane or the coexistence of liver abscess. Such cases have more than once been mistaken for cases of enteric fever, their real nature being only recognised when the liver enlargement had passed beyond the limit of any ordinary typhoid swelling. A case of the kind occurred in my own practice in January, 1874, and I failed to recognise its true nature until within three or four days of my patient's death; he died on the twenty-second day of his illness. The temperature trace in this case during the first week closely resembled the trace of enteric fever; there was meteorism, and spots resembling those seen in typhoid fever appeared and disappeared on the surface of the abdomen; there were no rigors, and but little sweating till near the end; the patient only once complained of pain in the hepatic region, and called it "spasm." Yet the post-mortem examination showed the bowel lesion to be that of dysentery, and the right lobe was occupied by a single large recent abscess (with adhesions), which should have been emptied during the patient's life, had its presence been recognised sufficiently early. In the case at present under discussion, such an error in diagnosis was precluded by the temperature trace, the absence of splenic enlargement, and the presence of those other symptoms which indicated from the first a condition of general blood-poisoning. The diagnosis of multiple abscess was strengthened by the use of the aspirator, a medium-sized needle, feeling as if always fixed in the tissues, and withdrawing only a small quantity of pus from three punctures made sufficiently far apart from one another. In Shanghai, where the usual liver lesion in connexion with bowel disease is a single abscess, the patient, even in such a case as the one just recorded, should always have the benefit of the doubt; and if pus flows at all freely by the aspirator, its use should, as a rule, be immediately followed by antiseptic incision and drainage, with the precautions which, I believe, Dr. Macleod (Shanghai) and I were the first to apply to the surgical treatment of liver abscess in January of 1878. Our first case (a successful one) is recorded in THE LANCET of June 22nd, 1878.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Enlargement of Median Nerve.—Fracture of Olecranon.—Diastasis of Lower end of Humerus.—Molluscum Contagiosum.—Obstruction of Mesenteric Vessels.

THE annual meeting of the Pathological Society of London was held on Tuesday last, Jan. 4th, J. Hutchinson, Esq., in the chair. The first hour was devoted to the usual business of the Society, and the closing half hour to the adoption of the annual report, election of officers for the ensuing year, and thanking the retiring officers. Dr. Horrocks and Mr. Barker acted as scrutineers of the ballot.

Dr. ORMEROD showed a woman, twenty-three years of age, with Enlargement of the Median Nerve. She was the subject of inherited syphilis, but had enjoyed good health till five years ago, when she suffered from an attack of pain in the left arm, worse at night, which passed off under simple treatment. Two and a half years later the pain recurred, and was felt shooting down into the fingers, and was gradually followed by paralysis and wasting. The median nerve is felt about the middle of the arm enlarged to the size of a big quill, firm, tender on pressure, which causes numbness in the thumb and outer fingers. There is wasting of the superficial flexor muscles of the forearm, and the ball of the thumb, with loss of normal response to the faradaic current; there is also anæsthesia in parts of the thumb and two adjacent fingers. When first seen the skin of these digits was glossy, thin, and slightly ulcerated, but is now healthy in appearance. In support of the view that this condition is syphilitic Dr. Ormerod referred to—(1) Absence of other cause, such as injury and cold; (2) the ulcers healed under the administration of iodide of potassium; he thought the swelling of the nerve was also less; (3) deafness due to affection of the inner ear or auditory nerve began or was aggravated in the year preceding the attack of pain.—The PRESIDENT believed the case to be unique; the fusiform enlargement of the nerve resembled that seen in leprosy, of which there was no trace here. Although he had never demonstrated neuritis in single nerves of the limbs in inherited syphilis, he had suspected it in some cases of numbness and great pain in the fingers; and similar affection of the optic and the cranial nerves was met with, so that he was disposed to think Dr. Ormerod's explanation correct.—Dr. ORMEROD stated that there was no optic neuritis or atrophy of the disc, only a little cloudiness of the media.

The PRESIDENT exhibited two living specimens. One was a man who fell back on to his elbow ten years ago, and fractured his olecranon transversely. He was treated with the arm in the flexed position, the fragment is fixed almost immovably to the back of the humerus, with a wide gap between it and the ulna, in which there appears to be not any uniting medium. The man has power in his triceps, and can partially extend the elbow; he also has partial paralysis of the ulnar nerve, with contraction of the ring and little fingers, numbness, and wasting of the muscles between the thumb and forefinger. On the other hand, he shows the signs of intra-uterine amputation of all the fingers. The second case was a little girl who had had separation of the lower epiphysis of the humerus, with displacement backwards, and anchylosis in that position. The Transactions of the Society contain a larger number of cases of diastasis than can be found elsewhere, and this induced him to show this case, which was the best marked he had ever seen.

Dr. THIN had examined a large number of sections prepared under his direction from upwards of fifteen Molluscum Contagiosum Tumours. With a single exception no hairs or sebaceous tumours were found in all these sections. It is evident, therefore, that the development of these tumours is attended by falling out of the hairs, and disappearance of the sebaceous glands. The molluscum formation has no duct, a breaking down of the central cells having been mistaken for a duct by some observers; and there is no sebaceous secretion in the cells. The tumour is composed of rounded epidermic masses, and not glandular elements. A molluscum tumour is formed by a small number of independent growths, beginning on the free surface of the epidermis, close to each other. These coalesce as they grow to form one tumour. In a favourable instance the primary point of origin was traced to a hair-follicle; and basing his opinion on appearances formed in one of the tumours, Dr. Thin, with Virchow, assigns the first abnormal action to the cells of the internal root-sheath. The hair drops out of the distended follicle, the sebaceous glands atrophy, and the follicle becomes enormously widened. New growths bulge out from the epidermic root-sheaths of the hair. The small group of independent points of development, whose coalescence goes to form the tumour, probably originated in inoculation by the discharge of molluscum cells from the follicle. As the morbid process can develop from the free surface of the epidermis, its origin in a follicle may prove to be not invariable. The development of the molluscum body from an epidermic cell takes place by the cell becoming first filled with granules, in the midst of which clear spaces (vacuoles) are seen. These granules enlarge, and finally coalesce into a homogeneous mass, the nucleus being pushed aside, and finally disintegrating and disappearing. In the full development an epidermic shell or wall contains a mass of homogeneous substance, which has special physical and chemical properties, and which is in reality a new product. It may fall out of the epidermic shell, and retain its shape and consistence. A molluscous body is an epidermic, and not a gland cell, whose natural evolution has been modified by the interference of an unknown cause. Everything tends to show that this cause comes from without, lodges first in the follicle, and there develops and multiplies, and infects the immediate neighbourhood of the follicle. The imperfectly-formed fibrous tissue that surrounds the tumour testifies to a certain amount of reaction set up by a substance which is foreign to the healthy tissues.

Dr. RADCLIFFE CROCKER showed specimens of Molluscum Contagiosum in a very early stage. The earliest showed the molluscous bodies in the rete mucosum, occupying the upper layers of the inter-papillary processes, together with those cells of the corneous layer which stained with carmine, while the external cells which took the picric acid stain were free from these molluscous cells. This change could also be traced in a minor degree into the deeper cells of the rete, as far as the palisade cells. In these specimens no alteration in the position of the palisade cells had yet occurred. In a tumour fully formed, but very small, a section through the centre of the tumour showed the wall of the duct-like orifice continuous with the epidermic layers of the skin, and within a plug of yellow cells, which did not stain with logwood or carmine, and which were in an advanced stage of the molluscous change. The evacuation of such a plug would give rise to the appearance of an open hair-follicle as commonly seen. Near this tumour transverse and vertical sections of hair-follicles could be seen with the molluscous change in the cells nearest the hair-shaft—i.e., in the internal root-sheath—so that the process evidently began in hair-follicles in some instances, though it seemed probable that it might also begin in the upper layers of the rete independently of the hairs. These observations were in accordance with the view that Virchow, followed by other Continental authorities, had put forward, and which Dr. Alfred Sangster had demonstrated two years ago in this country.—Dr. MORRISON had examined some specimens and was of opinion that the change began in the rete mucosum around the sebaceous gland, with great increase of the periplast; the gland itself is enlarged and softened in the centre; there was close similarity between these changes and those in the tissue of a wart from the scalp he had recently examined. He had failed to demonstrate the growth in connexion with a hair-follicle.

Dr. TAYLOR exhibited a specimen removed from a child aged five years, who was suddenly seized with vomiting and severe pain in the belly one afternoon; collapse ensued and the child died next morning. Dr. Taylor made the autopsy sixty hours after death. The peritoneal cavity contained about ten ounces of blood; the upper eight inches of the jejunum were turned up to the right and passed under a soft filamentous band reaching from the hepatic flexure of the colon to the mesentery; it was unaltered in appearance. All the small intestine below this was in its proper situation, but intensely congested and of a purple colour, which was obviously not due to constriction. The superior mesenteric artery was healthy for about an inch of its course, and was then completely obliterated for three-quarters of an inch by a firm semi-cartilaginous and fibrous mass; the branches coming off below this plug were not examined. At the same spot the mesenteric vein was filled with a soft thrombus. The congested intestine contained a few ounces of blood; the mesentery was thickened, as if from chronic inflammation, and the mesenteric glands were enlarged, but not caseous; other viscera healthy. During life the symptoms were attributed to eating strawberries. Dr. Fagge had recorded in the Transactions the case of an adult seized with severe abdominal pain who died in twelve hours; a thrombus was found in the superior mesenteric vein, and the small intestine had all the appearance of strangulation. In this case the obstruction of the artery was evidently not recent, and the question arose whether it had been suddenly completed by some twist of the gut, or whether the effects were produced entirely by the venous thrombosis.—Dr. D. POWELL asked what was the nature of the growth in which the vessels were imbedded.—Dr. TAYLOR had not examined it microscopically, but considered it to be merely the result of chronic inflammation of the mesentery.

The following card specimens were shown:—1. Calcareous Aorta, by Dr. R. W. Burnet. 2. Mucous Tumour of the Heart, possibly syphilitic, by Mr. Shattock. 3. Epulis, containing masses of hyaline cartilage, by the President for Dr. Lediard. 4. Diseased Kidneys from a young boar, by the President. 5. Specimens showing Gouty and Chronic Rheumatoid Arthritic Changes in the same individual, by the President.

The special business of the annual meeting was then despatched, and the meeting adjourned.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

On Maxillary Abscess and Necrosis in Childhood.

AT the meeting of this Society, on Dec. 15th, 1880, W. A. N. Cattlin, Esq., F.R.C.S., President, in the chair—

Mr. EDMUND OWEN read a paper on Maxillary Abscess and Necrosis in Childhood, and stated that the question he desired to suggest for discussion was this: Is it right to refuse to extract a carious and aching tooth on account of the acuteness of the periosteal and maxillary inflammation which its presence has excited? Mr. Owen felt that the knowledge of general surgeons on this point was by no means definite, involving, as it does, pathological and surgical principles of great importance, and he was anxious to get an opinion from those present, since he held that no surgeon should ever refuse to remove a tooth which is the cause of acute inflammation for the simple reason that the local disturbance is excessive. He would narrate three cases by way of analogy.—Case 1, that of a little boy in a most miserable condition, with a large bright red or dusky swelling at the end of his thumb. He can neither eat nor sleep, on account of the inflammation of the bed of the nail. The nail is evidently doomed, discoloured, and loose, and imbedded in a bleeding groove of vascular granulations. The nail is removed, water-dressings applied, cod-liver oil and iron prescribed, and the boy from that time recovers health and strength. *No* treatment which did not include the removal of the nail would have been of avail.—Case 2 is that of a child with acute periostitis and inflammation of the bone itself, with probably some periosteal suppuration, caused by exposure to cold and wet. A bold and free incision is made, which at once relieves the vascular tension, and the little patient recovers.—Case 3, that of a boy with the lower part of his face bound up, and his external ear plugged with cotton-wool. On removing the comforter, and with it a decomposing mass of moist linseed-meal, one finds the cheek red and swollen. He can only slightly separate the jaws, and one notices that one of the molars is slightly decayed. On pressure a small quantity of pus wells up between the tooth and gum, and near the angle of the jaw is a small opening, from which matter is discharging. The boy had been previously taken to a dentist, who refused to extract the tooth "until the inflammation had gone down," and advised the mother to keep on poulticing the cheek. Mr. Owen then drew attention to the course that the inflammation followed in the last case, the local disturbance having caused paralysis of the vaso-motor nerves, the Haversian arteries became crowded, and blocked with the red corpuscles. The colourless corpuscles effect their escape, together with some of the liquor sanguinis, and the protoplasmic contents of the lacunæ and canaliculi take on energetic proliferation. The bone becoming flooded with sanguineous effusion, and healthy nutrition being impossible, a portion of the jaw perishes, and frees itself by linear ulceration, and remains as a sequestrum. In operating, the less the wounding of the skin and the less the disturbance of the young teeth the better. In his experience necrosis of the superior maxilla was rare, whilst that of the inferior was not uncommon. In the case of the boy with the acutely inflamed tibia, we find that the result of those firm incisions has afforded complete relief to the vascular and nervous tension, and also a vent to the effused products, thus saving the compact bony tissue from a fatal flooding. And these same conditions are obtained in the case of the child with the maxillary distress, and prompt extraction would doubtless have spared the sufferer much subsequent trouble. In conclusion, Mr. Owen would venture to affirm that whenever a child is brought for assistance the more firmly fixed the jaws, and the greater the inflammation, the more imperative it is that the irritating cause and the vascular tension of the adjacent bone be simultaneously removed. The tissues will then settle down in quiet, as happily as did that red and swollen finger-tip when the removal of the piece of damaged nail was effected.—The PRESIDENT remarked that it was the practice of some to wait until inflammation had subsided, and he was a strong advocate for an early removal of the offending cause, as delay often greatly increased human suffering, and was, in many instances, injurious to the patient in after-life.—Mr. CATTLIN then narrated a case in which all the apparent symptoms of blood-poisoning were present. The water and drainage of the patient's house were good, and he had never been to sea. The breath was fetid, and the gums presented a warty appearance. The upper and lower extremities were studded with patches like ecchymosis, but no symptoms of purpura were seen in the mucous membrane of the mouth and elsewhere. The treatment consisted in a generous diet, with full doses of chlorate of potash and decoction of bark, which was afterwards changed for mineral acids and sulphate of iron and quinine. Under this treatment the patient slowly recovered, and in all probability the case was one of scurvy, brought on by other than the usual causes.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

THE second meeting of the present session was held at the Royal Kent Dispensary, Greenwich, on November 5th, 1880, Mr. H. W. Jackson in the chair, when W. Rivington, Esq., F.R.C.S.E., Surgeon to the London Hospital, read a paper on "A Wound in the Knee-joint treated Antiseptically." Mr. Rivington first gave a detailed account of the case and treatment, which went to show that it was a severe wound of the joint making a perfect recovery under the Listerian treatment. Mr. Rivington then said that it was unlikely the case would have gone on so well under the old treatment, and compared the issue of cases treated in former years under the old system and cases now treated under the protection of carbolic acid and carbolic gauze. Admitting that excellent results were obtained in the perfectly pure atmosphere of the country with a modified antiseptic procedure, and even without antiseptic precautions, Mr. Rivington said that the comparison must only be between cases which were treated in the loaded atmosphere of great cities and hospitals.

THE members of the staff of the Earlswood Asylum last week presented Dr. J. B. Spence with a gold watch on the occasion of his departure for his new post of medical superintendent of the South Stafford Asylum. The four night-nurses also presented Dr. Spence with a handsome biscuit-box.

Reviews and Notices of Books.

A Treatise on the Practice of Medicine. For the Use of Students and Practitioners. By ROBERTS BARTHOLOW, M.A., M.D., LL.D. London: H. K. Lewis. 1880.

A Text-book of Practical Medicine, with particular reference to Physiology and Pathological Anatomy. By Dr. FELIX VON NIEMEYER. Translated from the Eighth German Edition by GEO. H. HUMPHREYS, M.D., and CHAS. E. HACKLEY, M.D. Revised Edition. Two Volumes. London: H. K. Lewis. 1880.

A Treatise on the Theory and Practice of Medicine. By JOHN SYER BRISTOWE, M.D. Third Edition. London: Smith and Elder. 1880.

The Science and Practice of Medicine. By WILLIAM AITKEN, M.D., F.R.S. Seven Edition. Two Volumes. London: C. Griffin and Co. 1880.

TOWARDS the end of the year that has just passed there appeared almost simultaneously the four text-books on medicine which are named above. Three of them are already well-established favourites, and have run through several editions, but one is a new addition to the already rather numerous works from which the student has to make a choice; on this account we may give it the first place in this notice.

Its author is already well and favourably known in medical literature by his "Text-book of Materia Medica and Therapeutics." He indicates that his endeavour and aim have been to redeem medicine from the therapeutic nihilism that seems to be stealing over it; but, after all, the perusal of his pages does not lead us much farther in the direction of treatment than either of the other works we have named. Still there are many points of merit in Dr. Bartholow's book. It is concise, but is thoroughly up to date, and his references to recent pathological and therapeutical work are numerous. As an indication of the care with which he has followed the progress of events may be cited those passages on the treatment of acute rheumatism where he gives the conclusions arrived at by Dr. Greenhow in his recent papers upon the value of the salicylates. On another subject—namely, gastric ulcer—he advocates rectal alimentation by defibrinated blood—a method upon the good effects of which the Therapeutical Society of New York reported about a year ago, and which has been lately discussed at one of our London societies by Dr. Sansom. We may note here his recommendation of irrigation of the stomach in this disease, for diluting the gastric fluids and aiding the healing of an ulcer. Although he is careful to add that this should only be cautiously employed, it would, in our opinion, have been almost better not to have advised it at all, considering the obvious risks run by the procedure. For choleraic diarrhœa he alludes to the striking effects produced by the hypodermic injections of morphia and atropia. Considerable prominence is given to duodenal catarrh, an affection which, apart from its frequent concomitant, catarrh of the bile duct, is less easy to be differentiated from gastric catarrh than the author would have us believe. In speaking of the changes set up in the liver by occlusion of the bile-ducts, he mentions the researches of Charcot and Fagge—the latter name should have been Legg, to whom, indeed, belongs the credit of first drawing attention to these dangers, since termed by Hanot hypertrophic cirrhosis, and in another section he correctly mentions Dr. Legg's name in this connexion. There are good accounts of membranous arteritis and of dysentery, the former largely culled from Da Costa's memoir. In the chapter on intussusception we note an error, which, however, is very frequent—namely, that the most common of all forms of intussusception is that of the ileum through the ileo-cæcal valve. On the contrary, this is almost the least common, the ordinary variety being of the cæcum into the colon, the invagination commencing at the valve, and the cæcum, as it passes down, dragging the ileum after it. We are glad to find Dr. Bartholow gives the term "cirrhosis" the cold shoulder; but although, as he says, it is a "very inappropriate designation," it is, we fear, too firmly rooted in medical nomenclature to be ever set aside. Upon abscess of the liver he holds the dualistic doctrine of origin—viz., from portal pyæmia set up by dysenteric ulceration, and from a primary hepatitis. The treatment of hydatids of the liver is too brief, mention only being made of simple puncture and electrolysis, and no reference to the frequent supervention of suppuration and the indications for the free and complete evacuation of the cysts when so inflamed. The chapters on cardiac disease are fairly well up to date, and in the section on aneurism Sibson's statistics are quoted. Upon the treatment of aneurism, Tufnell's plan is advocated, especially when aided by iodide of potassium. Langenbeck's employment of ergotin, and Boehm's advocacy of barium on physiological grounds, are noticed; and it is pointed out that electrolysis has not been so successful as some of the above methods. The remarks upon the treatment of pleurisy open with these words: "The author wishes to protest against that revival in the belief of the aplastic power of mercury, and the return to its use in the treatment of serous inflammation, which is taking place in Germany." He himself advises the administration of quinine and morphia at the onset, with digitalis if there be much fever; local bloodletting in plethoric subjects, and strong counter-irritation. He recommends jaborandi, or the hypodermic injection of pilocarpin, and, so far as can be gathered, is rather an advocate of delay in paracentesis, unless the effusion be purulent. Phthisis is treated of under the three divisions—caseous, tubercular, and fibroid—a separate section being devoted to cartarrhal pneumonia. Croupous laryngitis is dealt with apart from diphtheria, and the local measures advised are chiefly in the way of solvents of the membrane, the need for tracheotomy not being referred to under the former head, and mentioned only to be mildly discountenanced (because there appears to be a "growing disinclination" for it) under the latter. In the other text-books before us a far more just and favourable view of the value of this important operation is taken. Space will not permit of further analysis of this latest text-book on medicine, which has many good features, not the least of which is the lack of pretentiousness about it, and the general accuracy of its statements; but it is capable of improvement, and its author will doubtless have opportunities for its revision as further editions are called for.

"Niemeyer's Medicine" hardly needs any special notice. The appearance of the translated edition some years ago was so well received, the book itself being so thoroughly scientific, that it at once became a favourite with English students. The present edition contains much, however, that its gifted author never wrote. There is hardly a chapter to which new matter has not been added by the editors, either in the form of short appendices at the close of the chapters, or incorporated in the text. A few subjects have been introduced not touched on by Niemeyer at all, and although this has been quite unavoidable in view of the increasing knowledge of the past decade, yet it is with mixed feelings that we observe this intermingling of matter from different pens with the original work of the author. It is some compensation, however, to find that the editors have refrained from presenting us with a transcript of the Seitz edition, where so much new matter was introduced that the original writing of Niemeyer had to be either condensed or mutilated. They have, on the contrary, restored much of the original text, and as far as possible kept it apart from the additions. Whilst confessing a preference for the original work, it would be wrong for us to maintain that as a text-book of medicine this work does not still rank highest.

Dr. Bristowe deserves great credit for the painstaking manner in which he sets to work to improve his treatise. Although it has run through two editions in four years, he has yet been able to give so careful and extensive a revision to the third edition that it is as much better than the second as this was than the first. The chief feature of the present edition is the introduction of an article on insanity, extending over nearly fifty pages. It is right and proper that this subject should be treated of in works of general medicine. The subject is one which, though of vast importance, is almost entirely neglected by the ordinary student. The excuse that it concerns him not, for his text-books are silent on the subject, can no longer hold; and if, taking Dr. Bristowe's summary as a guide, he seeks practical acquaintance with mental disease by studying its phases in an asylum, he will qualify himself for practice in a far more thorough manner than is the fashion. Now that attention is being once more called to the medical curriculum, it would be well for those who seek to restrict rather than expand its limits to consider the very great and obvious need there is for compulsory education in mental disease. Another feature of this edition is the introduction of many additional woodcuts, and, although these might be almost indefinitely extended, the number already given add greatly to the utility of the work, which, as it stands, is thoroughly representative of modern medicine. If the next edition could be brought out, even more profusely illustrated, especially with pathological drawings, and if at the same time the work could be conveniently divided into two volumes, it would leave nothing to be desired.

But if Dr. Bristowe's work might well be distributed over two volumes, what should be said of the ponderous tomes of which Dr. Aitken's older and well-established treatise now consists? It contains matter sufficient to fill four volumes, and these of considerable size. The author has certainly aimed at making his book encyclopædic. Whether it has become more readable by the process is matter for doubt; but its value as a standard work of reference has been *pro tanto* enhanced. A great part of the book has been rewritten, especially that which required most rewriting—viz., the nervous system; and here free use is made of the writings of Jackson, Gowers, Charcot, and others. Dr. Aitken is most careful and candid in giving authorities for all his statements—the text fairly bristles with their names. There is so much that is excellent in these volumes that it is with regret we feel compelled to admit that the work is less suitable for the student than any of the others we have above noticed. To the physician, however, Dr. Aitken's work is most valuable; and it is a book which should be on the shelves of every medical library. Besides, it contains much information not usually met with in works of this class.

Health Lectures. Delivered in Manchester, 1878–79–80. Printed by the authority of the Manchester and Salford Sanitary Association. Manchester and London: John Heywood. 1880.

THE Association under whose auspices were delivered the lectures collected in this little volume has for its objects—1. "To promote attention to personal and domestic cleanliness, and to the laws of health generally. 2. To aid the constituted authorities in the promotion of sanitary improvements." The first of these objects is worthily fulfilled by these lectures, which are all written in plain and simple language, and enforce the vital truths of hygiene. Reproduced in a cheap form (each separate lecture can be obtained for one penny), they should have a wide circulation among the classes most in need of such instruction. The subjects are well-chosen—water, drainage, alcohol, food, ventilation, nursing—these and other topics are dealt with in a practical manner, and mostly with arguments appropriate to the audiences before which they were delivered; and when it is added that the lecturers include Drs. Dreschfeld, Ransome, Simpson, Holgate Owen, Irwin, Humphreys, Tatham, Ashby, and Sutton, it will be seen that the medical profession of Manchester have taken a great part in this good work of preaching the gospel of health.

NOTE ON THE DIAGNOSIS OF CAVITY IN THE LUNG.

To the Editor of THE LANCET.

SIR,—Would you permit me to refer briefly to the physical sign alluded to in your issue of Dec. 18th by Mr. Solomon Charles Smith of Halifax, under the title of "Note on the Diagnosis of Cavity in the Lung." Mr. Smith describes a sign which he has found present in cases of lung cavity—viz., a blowing sound audible in the trachea synchronous with the first sound of the heart. This tracheal bruit—which is evidently an expiratory sound—was described and demonstrated by me as occurring in cases of thoracic aneurism, before the Northumberland and Durham Medical Society early in October, and was noticed by some of the medical journals—viz., *Medical Press and Circular*, Oct. 27th, p. 359, and the *Dublin Journal of Medical Science*, November, p. 464.

Since first observing this sign, now about eight months ago, I have carefully looked out for it, and have only found it to be well marked in cases of aneurism of the thoracic aorta. I first discovered it in healthy individuals after violent exercise, and subsequently noted its existence in aneurism when the patient lay quietly in the recumbent position. It is best developed by making the patient inspire deeply, and then closing the mouth to expire slowly through the nasal passages.

In aneurism—for I do not deny its existence in lung cavity, though I have not found it myself—I think it is to be explained by the sudden systolic expansion of the sac pressing upon the lung or air-tubes, and expelling air from the chest cavity, thus causing a puffing sound synchronous with the systole, and audible in the larger tubes and trachea.

In healthy people the sound is produced by the sudden "over-distended" arch pressing in a similar way as the result of exercise.

I think Mr. Smith's explanation of the sign, even supposing it to exist in cases of pulmonary cavity, is scarcely tenable. He says, "obviously produced by the impact of the contracting ventricle against a neighbouring cavity." For surely the impact is directed forwards and away from the site of lung cavities; and, again, systolic contraction of the ventricle means a diminution in the size (bulk) of the heart, thus inducing occasionally, as is well known, a short inspiratory puff, the result of the rushing in of air to the parts of the lung adjacent to the heart.

I remain, Sir, your obedient servant,
DAVID DRUMMOND, M.A., M.D.,
Physician to the Newcastle-on-Tyne Infirmary,
Lecturer on Physiology, Durham University.

Newcastle-on-Tyne, Dec. 21st, 1880.

COLLEGIATE PRIZES.—It is stated that only two essays have been sent in for the Jacksonian Prize of the Royal College of Surgeons on "The History, Principles, Practice, and Results of Antiseptic Surgery;" the time for sending in essays having expired on the 31st ult. For the present year the subject for this prize is, "The Pathology and Surgical Treatment of Diseases of the Hip-joint." The subject for the Collegial-triennial prize, to be awarded in 1883, is "The Relations between the Radicles of the Lymphatic System and Capillary Vessels." The prize consists of the John Hunter Medal, executed in gold to the value of fifty guineas, or at the option of the successful author of the Dissertation of the said medal executed in bronze, with an harmonium of £50. The competitions for both are confined to members of the College.

THE LANCET.

LONDON: SATURDAY, JANUARY 8, 1881.

THE defects of medical education and examination become more conspicuous every year. There is now no disagreement as to the fact. Judged by every standard the existing systems of medical education are faulty. Compulsory examinations have had a long, and, upon the whole, fair trial, but they have failed to react, as it was thought they would, in a wholesome manner upon education. From the educationist's standpoint the principal outcome of compulsory examinations is "cram." Training and culture have not only not become better, but they have deteriorated. A point has been now reached from which many sagacious men profess to see disappointment and ultimate disaster if precisely the same lines are followed as heretofore. How to avert these? and how to attain success? these are the questions.

It is always easier to detect an evil than to find an appropriate remedy. The letters which have appeared and are appearing in our columns testify to the difficulties that beset the path of the reformer. Various suggestions have been made for the improvement of medical education—namely, a stricter preliminary examination, the institution of a compulsory preliminary scientific examination, the revival of the system of apprenticeship, elimination of some subjects from the medical curriculum and limitation of others, and, finally, an extension of the time devoted to medical studies. It is curious to find that almost every writer has been content to propose a single specific. Mr. SAVORY, for instance, advocates an extension of the medical curriculum to seven years, while Mr. HEATH proposes a sort of modified extension of time by requiring that two clear years should elapse between passing the primary and presentation at the final professional examinations. Mr. BUTLIN would eliminate some of the subjects at present included in the list of professional studies and would limit others, while Mr. BRUCE CLARKE would be satisfied to see the standard of preliminary education raised. Dr. STRANGE deals more thoroughly with the matter, and recommends not only an extension of time given to professional study, but a revival of the system of apprenticeship, and elimination from the strictly medical curriculum of chemistry, botany, materia medica, as well as physics and zoology; all of which should be mastered before the purely medical studies are begun. Dr. STRANGE would further make the curriculum to extend over five years, two of which should be spent in pupilage at a hospital or dispensary, or with a general practitioner in large practice.

There is too much reason to fear that no single remedy will correct all the faults of medical education. The regulations and requirements need to be entirely reconsidered. One thing is certain; any change must necessarily increase the cost of the medical education both as regards time and money. It is, perhaps, not of much importance at what period the greater portion of the increased cost is borne, whether during school-life or later on during the medical curriculum. That an improvement in the general education of the bulk of medical students is desirable, few who have had any experience as teachers will deny. While the standard of general education throughout the community has been raised during the past fifteen years, few of the bodies who conduct the preliminary examinations for the medical profession have made their scrutiny more strict. Indeed, in some instances the test has been actually lowered. The time has now come when a better general education should be insisted on. It may be true that some good practitioners of the present day as well as of the past may not have been men of much general education but they have succeeded, not because they lacked culture, but in spite of this drawback. A good general education may be to some extent a matter of accident or opportunity, but it is at the same time, in no small degree, a criterion of good social and intellectual antecedents. By enlarging the requirements as regards general education much may be done to raise the status and influence of medical men by attracting a better class of candidates into the ranks of the profession. On the other hand, as we endeavoured to show in a recent address to students, the preliminary education should be as far as possible *general;* after this, and before the strictly medical studies are begun, some time, a year or more, might advantageously be given to the study of the natural sciences, as physics, chemistry, botany, zoology, as a sort of introduction to the *technical* part of the student's training. This is already done at the universities. By these means the medical curriculum would be lightened, and more time could then be given to anatomy, physiology, midwifery, medicine, and surgery. This would really be tantamount to extending the time devoted to medical studies. Another suggestion for improving medical education is that of reviving the system of apprenticeship. In the address referred to (see THE LANCET, Sept. 11th, 1880, Students' Number) we called attention to some of the advantages of a short period of pupilage. But granting its advantage, it would be a question whether the term of pupilage should wholly precede study at a medical school, or should wholly follow, or be divided, a portion preceding, and a portion following, the sojourn at a medical school. For the complete education of a medical practitioner there are certain advantages in the latter course. A few months passed, at the beginning of his career, under the supervision of a well-informed practitioner either in general practice or in a small hospital or dispensary, would prepare the student for studies at a medical school. In a very short time some acquaintance with anatomy and materia medica might be formed and a respectable skill acquired in minor surgery and pharmacy. There would then be less risk than at present of the three or four years passed at a medical school being wasted. But those who advocate a return to some form of apprenticeship, do so chiefly on the ground that in no other way can the "mystery" of practice be acquired. The majority of those who now obtain qualifications are ignorant of the nature of general practice. Something might be done to remedy this, by requiring that all who wish to engage in practice should, after passing their examinations, spend six months or a year with a qualified practitioner. Such a regulation was in vogue in the kingdom of Naples six hundred and fifty years ago. Students were then compelled to apply themselves to the study of logic for three years before they commenced the study of medicine, which was itself to be pursued for five years. After this the candidate had to undergo two examinations for his licence and doctorate before the masters of the school of Salerno, and then to spend a year upon trial under an expert physician before he was allowed to practise on his own account.

◆

THE transmission of diseases supposed to be peculiar to one class of animals, by means of inoculation, to animals of another class, is a matter not alone of theoretical interest, for it has been the means of extending largely the sphere of observation on the pathology of a most important class of maladies. Much interest, therefore, attaches to any attempt to ascertain whether such diseases, hitherto supposed to be limited in their incidence, are or are not so limited by constitutional peculiarities. An important series of researches on this point have been undertaken by M. COLIN of Alfort, who has endeavoured to learn whether glanders can, as was asserted long ago by DUPUY, be transmitted from the solipeds to the rodents, and, in doing so, has brought out prominently some important pathological facts relative to the disease. In some experiments made with this object twelve years ago, M. COLIN discovered that the inoculation of the rabbit with the poison of glanders gives one of four results. Death may occur rapidly without visceral lesions; there may be extensive and deep ulceration at the places at which the inoculation was made; it may cause more or less pronounced tuberculisation in the lungs; no appreciable effects of any kind may follow. In some recent experiments upon this subject, M. COLIN has endeavoured to solve the following problem:—If there are two elements in the products of glanders, the one a virus capable of transmitting the specific disease, the other tending to cause tuberculisation, it is necessary to submit the various morbid products to comparative experiment, because these two elements may be found separate, or capable of dissociation. In many experiments the results have seemed to harmonise with this theory of separable poisons, although in previous observations their dissociation has not been obtained. M. RENAULT, who succeeded in transmitting glanders to the sheep, goat, and dog, found the complete disease was generated; in each species of animal there were both nasal ulcerations and pulmonary tubercles. In each the disease was fatal, and demonstrably virulent, since from each it could be retransmitted to horses in its perfect form. But it had already been noted that in man this was not always the case. In rare cases human glanders presents all its characters and virulence, but more frequently only local lesions are produced, unhealthy wounds, abscesses, ulcerations, fistulæ, &c., without appreciable complications in the lungs, and with no appearance of a contagious character. It is rarely that surgeons acquire glanders from the inoculations to which they are exposed in operations on infected subjects, and in post-mortem examinations on those dead of the disease.

The receptivity of the rabbit for the poison of glanders is considerably less than that of man, and M. COLIN has found that in the rabbit the evolution of the disease seems to become arrested at different periods, causing lesions which vary very much in different cases, and which seem to indicate both the complexity and the separability of the elements of virulence. After the insertion of the virus in the substance of the skin or in the subcutaneous cellular tissue, a conical prominence often presents itself at the seat of the inoculation in the course of twenty-four hours, often surrounded by a zone of erythema, beneath which is a phlegmonous œdema. After the appearance of this prominence pyrexia sets in, and the temperature may rise to 106° F. This state of affairs lasts for four or five days without other alteration than the extension of the redness, and sometimes an enlargement of the nearest lymphatic gland. If death does not occur without further symptoms, the local state undergoes a modification: the swelling lessens, the redness and heat subside, a small adherent crust covers the apex of the prominence, and there is no noticeable process of ulceration or suppuration. At the end of the second week these local changes may have disappeared without other trouble. More frequently, however, the local swelling persists, its base becomes indurated, and an ulcer forms, more or less deep, with irregular borders. This second phase of the local accidents may last two, three, or four weeks, and then gradually lessen, and cicatrisation may take place. From this time the animal either recovers its usual state of nutrition or remains languid, becomes tubercular, and ends by dying with serious lesions in the lungs, kidneys, and other viscera, and even with morbid changes in the muscles and articulations.

It is thus evident that in the rabbit the disease advances by stages, at the end of each of which death or recovery may take place. Even in the most severe cases, the whole series of symptoms observed in the horse are not reproduced. In this respect the course of the disease bears considerable resemblance to the features which it presents in man. It is, therefore, of interest to inquire why these remarkable variations in its course occur. In some cases in which death occurred with great rapidity, M. COLIN attributed it to septicæmia, although only a small quantity of fresh blood had been taken from a horse immediately after it had been slaughtered. Death occurred, however, in just the same way when a drop of liquid was taken from a living animal upon the point of the lancet, and the absence of septicæmia was proved by the fact that the rabbit's blood, taken immediately after death, had no effect when inoculated into another rabbit. When the animal dies only at the end of five or six months, the cause of death is always pulmonary tuberculisation, which is slighter in degree than that which occurs in consequence of tubercular inoculations. Tubercles and caseous foci are scattered through the lungs; the pleuræ and the kidneys show also a considerable number, and some are found in Peyer's patches, and in the mucous membrane of the small intestine. Moreover, many articulations may be invaded by caseous or tubercular disease, especially the scapulo-humeral, the femoro-tibial, and the tibio-tarsal.

Thus, the disease is represented by pulmonary lesions, as in the horse, and by articular lesions, as in man. But the ulcerations of the nose, larynx, trachea, and the lesions of the skin are absent. The disease is incomplete, killing under the form of a tubercular disease. Differences from the effect of the inoculation of tubercle, however, are that in glanders the lymphatic glands swell much less than they do after the inoculation of tubercular material; they become slightly indurated, and undergo caseation either not at all, or only in minute spots after a long period. On the other hand, after the inoculation of tubercle, the glands often attain enormous dimensions. After the inoculation of glanders, the tuberculisation of the lung is slow, and apparently, to judge by the general condition of the patient, may be arrested or suspended, and it is often insignificant; there is never the pronounced phthisical condition which follows the inoculation of tubercle. In a large number of cases the rabbit inoculated with glanders recovers its health after the local troubles, and the disease presents in general the remarkable peculiarity that it appears to be virulent and may kill at an early period, and loses its virulence later, even after having caused a certain amount of pulmonary tuberculisation. M. COLIN took from a rabbit, dead on the sixth day after inoculation with glanders, some serum from the œdema adjacent to the local tumour, and also some pulp from a neighbouring lymphatic gland. These two products were separately inserted into the skin of another rabbit, one into the right flank, the other into the left. At the end of seven hours the skin of the flanks began to redden, and the next day the redness had invaded the whole lumbar region, and there was already fever and loss of appetite. The symptoms increased, and at the end of ten days ulceration commenced. At the end of a month the ulcers were dry, and the animal's general state began to improve. After three months and a half it was killed. All internal glands and organs were healthy, and thus this, so to speak, second generation of glanders had become arrested in mid-development. When the disease has arrived at the stage of pulmonary tuberculisation it is no longer inoculable, either by means of the blood, the serosity, or the tissue of the glands. But tubercle at this stage is just as inoculable as in any other. Hence M. COLIN draws the conclusions—(1) That glanders is not a simple disease which always runs its course, but is constituted by a series of elements which succeed one another, and the links between which may at any point be broken. (2) That virulence is not necessarily and constantly combined with the disease. It exists at the commencement, and may be lost later, even although the disease progresses and tends to become fatal. It is probable that there are many diseases of similar constitution, of common origin and identical nature, which by the different aspect they present in one animal or another, appear to be different affections, the origin of which is not evident. Hence, when an attempt is made to establish the identity of a disease by means of experiment, an animal must not be selected in which the disease does not run a complete course. If, for instance, it is desired to test by inoculation whether a given disease in man or the horse is or is not glanders, the rabbit should not be chosen, since the indications which it gives are not decisive.

◆

THE needs of society increase as the square of its density. In primitive times, when the population was sparse and the habitations of men were few and far between, it was possible, when persecuted by sickness in one locality, to flee to another; and although, even in the early days of world-history, disease was doubtless disseminated by this policy of migration, the harm was less than would have accrued to that of remaining stationary and running the risk of self-infection. Isolation of the sick was one of the first, because it has ever been the most obvious, of measures for the arrest of contagious or infectious—or let us mask our ignorance, and say "catching"—maladies. The *leper*—who was probably a typical sick-man rather than a person suffering from any particular disease—soon came to be shut out from intercourse with his fellows until he was cured. And then—that is when he *had* recovered—he was required to remain apart until he had undergone some special processes of disinfection applicable both to his person and his clothes, which, like the isolation to which he had been subjected during his illness, were designed as much for the protection of the community as his own benefit. The scientific researches of the last half-century have resulted in the acquisition of a vast amount of knowledge in relation to the genesis and the exodus of disease, and thrown a flood of practical light on the need and efficacy of these precautions.

It cannot be denied that society has — doubtless moved by its fears — evinced considerable alacrity in learning the lesson of "going without the camp" and "standing apart," as sanitary expedients, but this would seem to be all it has learnt; and, even now, with all our nineteenth-century sagacity, we are only just beginning to grasp the notion that mere "quarantine," however rigorously enforced, will not do everything, or even the half, of what is requisite. Segregation is only a remedy for the evils incident to aggregation in so far as it gives time and opportunity for the dying out of the *materies morbi*, which happens to be particularly short-lived if not quickly supplied with a new *nidus*. The robust germ—or sperm, whichever it be—is not killed, it is not even scotched, by being cast off or deposited or allowed to fall into what seems to be a process of atrophy *in situ*. Its animation may be suspended, but vitality remains, and like the desiccated lymph on the vaccine point, or, possibly, the dormant virus of rabies lying fallow in the system of the man who has been bitten by a mad dog, it only sleeps, and may at any moment be infused with new energy. Society, if not the State, is, we say, beginning to recognise these facts, and may, perhaps, before long, be willing to act upon them.

Meanwhile there is an especially self-evident consideration which would scarcely seem to have dawned on the popular intelligence—namely, that very little can be gained by the isolation of fever patients in hospitals and outbuildings, if at the commencement of convalescence they are to be brought straight back into the midst of society, without undergoing a process analogous to that of the purification ordained for the leper. It matters nothing to the general cause of public health whether the patient recovering from a communicable disease is removed to his own home, or placed for a while among strangers. It is a purely selfish policy which prefers to send the convalescent to the seaside, or into some rural village for a few weeks, before he is allowed to re-enter his family. The real danger of infection is not lessened by this device; but the instinct of self-preservation has hit on the sagacious expedient of shifting the peril from self to others. This is where and how well-conceived, but imperfectly executed, measures for the "stamping-out" of disease break down. Human nature is selfish, and if by a simple process of isolation disease can be kept out of a particular household or family circle, its promoters are abundantly satisfied. They care nothing who else may "catch" the disease, so that they escape. Until broader and less selfish views are popularised, there can be no such thing as disease extermination.

The policy of special and limited isolation, or "quarantine," receives its *reductio ad absurdum*—as a pretentiously rational artifice for allowing disease to die out if its germs happen to be peculiarly mortal—when a patient suffering from one of the exanthematous or intestinal fevers is kept apart so long as the pyrexia lasts and the *malaise* continues, and then turned adrift on the community at the particular period when the *materies morbi* is passing off by the desquamation of cuticle, the shedding of epithelium, or the unloading of follicles and open glands. In some maladies—scarlet fever, for example—the period of exfoliation is the time of special danger. It is one of the marvels of modern thought that we do not, will not, work out the logical consequence of the general policy to which we commit ourselves. We seize on an idea suddenly and clumsily, often making believe to "discover" what has been staring us in the face for ages, and impulsively put it in practice; but if any one ventures to suggest that some secondary but necessary notion lying a hand's breadth beyond the range of eager vision is part and parcel of the original idea, he is sure to be looked upon as a pessimist or shunned as a dreamer.

We venture to hope this may not be the fate of those who are now striving to convince the public that "homes" for the reception of patients recovering from scarlet fever, but still in peril themselves and a source of danger to others, are absolutely needed. There can be no doubt of the entire accuracy of the representations which are being made. Indeed they understate the urgency of the requirement. It is not merely that society is now exposed to grave risks from special cases. The periodic "visitations" of this and kindred maladies which invade the community and cut off valued and sometimes useful lives are in great part due to the shortsighted practice of sending patients to the seaside and out-of-the-way places during convalescence. When one individual "catches" a communicable disease in a locality which appears to be free, or almost free, from the malady, this is because some other individual has at a former period left the poison or seed of disease where it is now found. It is difficult, generally impossible, to trace the connexion between the two links in the chain; but they are practically and substantially related, as would be the person who left a tube charged with vaccine lymph in a drawer, and some other person who, months afterwards, rummaging in the same drawer, found, and, accidentally breaking the tube, wounded and inoculated his finger. It is important to remember this, because nothing could be gained, but the sources of mischief would be multiplied, by the mere creation of additional depositories for the *materies morbi* of scarlet fever or any other disease. We do not want a "convalescent home for scarlet fever," as the leading journal curiously puts it, but a house or houses where convalescents from that disease can be purified and the débris of their morbid tissues destroyed. If nothing is to be done with a view to the imprisoning and destruction of the extruded particles of organic poison, no great good will be accomplished. Practical sanitarians would do well to turn their attention seriously to this matter of disease-germicide (another form of vivisection) coincidental with the endeavour to supply the metropolis with homes or refuges for the convalescent from scarlet fever. It must, however, be confessed that a great deal of nonsense has been written and spoken about the efficiency of "disinfectants" and "antiseptics." If it were possible to immerse every particle of diseased organism in a globule of carbolic spray, the virus of disease *might* be devitalised, though even this is doubtful, so tenacious of life are the mischief-working elements and agents of mortality. No more confidence can be reasonably placed in fumigations than in intestinal flatus, which probably do not touch the particles they are meant to influence, or washings that do even detach the clinging fragments of cuticle or fabric pellets of excreted débris, from the meshes of the fabric in which they are entangled. Let anyone who reposes great confidence in the popular methods of "disinfection" try an experiment so crude as that of attempting to slaughter a cloud of gnats with a mitrailleuse-like shower of strong carbolic spray, or set himself to cleanse a square foot of woollen or even linen cloth from the impregnations of sooty smoke. It is easy to theorise on the action of disinfectants, but a vastly different matter to test their application *practically* and thoroughly with apparatus capable of a minute observation of results. We are not seeking to discourage sanitarians, but it is desirable to point out that the need of establishments for the isolation and disinfection of the convalescent from fevers, particularly the exanthematous, is as great as it is urgent, and that mere isolation will not suffice if disease is to be stamped out—as there is scientific reason to believe it might be—if society only deemed it worth the pains and expense to make a serious onslaught.

◆

THE Guildford Rural Sanitary Authority are about to have the opportunity of considering, on the motion of one of the members, the propriety of reappointing the district medical officers of the union medical officers of health, each in his own poor-relief district. We assume from the terms of the motion that this arrangement has been found as unsatisfactory in its working here, in view of the performance of a medical officer of health's duties, as it has been found elsewhere; and we welcome this indication of rural sanitary authorities themselves, on the instigation of their own members, taking this subject into consideration. Hitherto it has rested with the Local Government Board as a general rule to initiate action in this direction, but this is much less satisfactory than a rural sanitary authority itself raising the question, and considering it in the light of recent experience. It is true that the Central Authority has for some time intimated that they look with disfavour on the appointment of district medical officers as medical officers of health, and no doubt this opinion has been communicated to boards of guardians acting as rural sanitary authorities generally. Nevertheless these officers do so act in not a few districts, but accumulating experience declares more and more against associating the two sets of duties in the same hands

Theoretically considered, there is much to be said for having the medico-sanitary supervision of a district in charge of the individual who has the medical relief of the poor. The nature of his medical duties seems so eminently adapted to facilitate the execution of public health duties, and in a few exceptional cases this may really have been the case. But the general experience of these appointments tells decisively to the contrary. The invidious position in which a practising medical man is placed with regard to his patients in exercising public health duties operates in the most formidable manner with a practitioner whose livelihood depends upon his practice, however conscientious he may be, in deterring him from the strict performance of these duties. Moreover, the exigencies of practice are too commonly inconsistent with the due performance of public health functions, particularly in times of epidemic diseases, when the calls of medical practice and requirements of public health duty both reach a maximum, and one must needs be sacrificed to the other. Of necessity, in these circumstances public health goes to the wall. Then, again, the district medical officer is placed in a peculiar position towards his sanitary authority. Hitherto his pay as medical officer of health has been held as simply a petty addition to his salary as district medical officer. No opportunity has been lost of impressing upon him, in actions if not in words, that medical relief duties are of infinitely greater importance in the eyes of his authority than public health duties. The object of his appointment as medical officer of health is thus very seriously frustrated from the beginning, and the district medical officer perfectly well knows that (the regulations of the Local Government Board notwithstanding) he is not expected to do more—that is to say, not to give greater value to his public health work—*than he is paid for*. What wonder then, these points alone considered, that the appointment of district medical officers as medical officers of health has generally proved fatal to the due performance of the duties of that post.

Let us hope that the Guildford Rural Sanitary Authority will set a wise example, and merge the appointment of their several district medical officers of health into a single appointment, to be held by a medical man not in practice.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

THE proposal to hold during the International Medical Congress an exhibition of sanitary and medical apparatus is one which we trust will meet with that success which it appears to us to deserve. It is obviously desirable at a time when British and foreign medical practitioners will be assembling in London in unprecedented numbers to discuss the various scientific questions connected with medicine, that an opportunity should be afforded to those who are mainly occupied in aiding and abetting the practice and art of medicine, of displaying before the profession and certain sections of the public all that is best and newest for the prevention, the detection, and the cure of disease, and for the alleviation of those whose sufferings are incurable. It was perhaps impossible for the Congress, as such, to organise an exhibition; and it is fortunate that a representative body like the executive committee of the Parkes Museum, composed of men who are well known as sanitarians, physicians, and surgeons, was found ready and willing to take upon itself the trouble and responsibility of such a task. Although the Congress has relegated the duty of organisation to an independent body, it has nevertheless marked its approval of the scheme by a formal resolution passed at a meeting of the Executive Committee on November 16th; and the president-elect of the Congress in his private capacity seconded the application which was made to the Commissioners of 1851 for space at South Kensington. The application made to the Commissioners has been acceded to, and a certain amount of space in the buildings at South Kensington has been granted for the purposes of the exhibition. Directly the space was granted the executive committee of the Parkes Museum held a meeting and passed a resolution to the effect, as was stated in our issue last week, that they were willing to organise the exhibition, "*provided a sufficient guarantee fund be obtained.*" This is a necessary proviso, for the Parkes Museum has no funds available for such a purpose, and it could not be expected of the members of the executive committee to take the risks of such an undertaking on their own shoulders. We doubt not that a guarantee amply sufficient to cover all risks will be forthcoming, for it would be very short-sighted of those engaged in medical industries to allow the opportunities for an exhibition which the current year will afford, not to be utilised. For the purposes of this exhibition a sub-committee will be formed by the executive committee of the Parkes Museum, and certain persons of eminence connected with the pharmaceutical and other medical and sanitary industries will be invited to join it. It is proposed, we believe, that the exhibition should open about the middle of July, and close with the Congress (on August 9th), and it is also proposed that on the two final days of the exhibition sale of articles should be allowed, in order to afford visitors to the Congress an opportunity of acquiring any object they may desire. The scope of the exhibition is to be wide, and all branches of sanitation will be included. In addition to sanitary apparatus, there will be classes devoted to the exhibition of—1, hospital construction and arrangement; 2, surgical instruments and apparatus; 3, appliances of the ward and sick-room; 4, drugs, disinfectants, and medical dietetic articles; 5, electrical and optical apparatus; 6, microscopes and other apparatus used in the investigation and relief of disease; 7, appliances used for the treatment of sick and wounded in time of war.

PATHOLOGICAL SOCIETY OF LONDON.

AT the annual meeting of the Society, held on Tuesday last, the members nominated by the Council as officers and Council for the ensuing year, published in our last number, were duly elected. The annual report, read by the secretary, showed the Society to be in a very flourishing condition, the number of members is gradually increasing, and now reaches the high total of 635, while the balance in the hands of the treasurer is more than £100 larger than that remaining twelve months ago. Dr. T. S. Dowse moved that the reports of the Council and treasurer be adopted and printed in the next volume of the Transactions; this was seconded by Mr. W. A. Meredith, and carried. Mr. Pollock proposed a vote of thanks to the President, J. Hutchinson, Esq., for the very able manner in which he had filled the office during the last two years, and spoke in high terms of the value of Mr. Hutchinson's services. It was carried by acclamation, and responded to by the President, who expressed his indebtedness to the Council, secretaries, and members of the Society for their co-operation and support. When elected President he was anxious that the meetings of the Society should be as attractive as possible, and, remembering what a useful school they had proved to himself, he was desirous that as many specimens as possible of the rarer pathological changes should be exhibited, and that the Transactions should be enriched with original and, as far as possible, thoroughly trustworthy communications. The difficulty in carrying out such a plan lay in the want of time; he had therefore suggested the plan of showing some specimens by card, without oral description, and, although the plan was still on its trial, he thought it was working well, and would be found to be very useful. He had hoped also to be able to place the Society in connexion with provincial pathological societies, and to exchange the more valuable specimens shown, but hitherto this had not been arranged. He thought it very desirable to encourage the exhibition of living illustrations of pathological changes, and for this purpose some fresh and better arrangements for their display were necessary. He had found regular attendance at the meetings very useful, and was sorry that he should lack the compulsion to attend them in the future. Dr. Longhurst and Dr. D. Powell proposed and seconded a vote of thanks to the retiring vice-presidents and members of council for their services. It was carried, and briefly acknowledged by Mr. J. R. Godlee. A vote of thanks to the retiring secretary, Mr. Morrant Baker, was proposed by Dr. Ord in eulogistic terms, seconded by Mr. McCarthy, and carried by acclamation. Mr. Baker, in acknowledging the compliment, referred to the able and courteous assistance at all times rendered him by Mr. Wheatley.

MIND IN WORK.

IT is set forth on the highest authority that whatever we do should be done with our *might*. This precept being interpreted means that there should be mind in work. The difference between a work of art and the product of machinery lies in the presence of a mark of mind directing the handiwork in the one case, while the other is simply a predetermined result produced by a duly formulated process wherein or whereby physical forces are directed and controlled by other physical forces on a set plan, to perform a defined series of actions, which *must*, in the nature of things, end in the production of the effect foreseen. Mind sets the one process, or series of processes, in operation, and they work out their physical destinies. In the other, mind is the active controlling power throughout. Starting from these premisses, we are now concerned to point out that little or no success can be expected in any calling which does not suit the temper and bias of the mind pursuing it. There cannot be "might" or earnestness—of the best sort—in an uncongenial enterprise. It is not necessary that an occupation should be ardently loved, but it is indispensable that there should be some special fitness for a calling if the powers of mind are to be resolutely and effectually engaged. Medical men see a great deal of life, and nothing strikes the observant family practitioner more than the number of feeble, sauntering, and loitering minds with which he is brought into contact. No inconsiderable proportion of the common and some of the special ailments by which the multitude are affected may be traced to the want of vigour in their way of living. The human organism is a piece of physico-mental machinery which can only be successfully worked at a fairly high pressure. It will almost inevitably get out of gear if the propelling force is allowed to fall below a moderately high standard of pressure or tension, and that degree of tension cannot be maintained without so much interest as will secure that the mind of the worker shall be in his work. It is curious to observe the way in which particular temperaments and types of mental constitution are, so to say, gifted with special affinities, or predilections for particular classes of work. The men who work in hard material are men of iron will, which is equivalent to saying that the men of what is called hard-headed earnestness find a natural vent for their energy in work that requires and consumes active power. On the other hand, the worker in soft materials is commonly either theoretical or dreamy. There is a special type of mental constitution connected with almost every distinct branch of industry, at least with those branches which have existed long enough to exercise a sufficient amount of influence on successive generations of workers. We are all familiar with what are called the racial types of character. It would be well if some attention could be bestowed on the industrial types, both in relation to educational policy and the study of mental and physical habits in health and disease.

EDINBURGH ROYAL INFIRMARY.

DURING the year ending Oct. 1st, 1880, 5013 patients were admitted into the infirmary; of these 2559 were dismissed cured, 1439 relieved, 423 on other grounds, while 436 died; 358 were cases of fever. The daily average number of patients was 469, and the average time of residence in the house was 31·6 days; 15,000 out-door patients were attended to. The ordinary income for the year was £21,540, and the ordinary expenditure £27,818, the excess of expenditure being more than met by the extraordinary income, which for the year amounted to £18,255. During the year the managers had paid £28,691 on account of the cost of the new infirmary, and it was thought that £20,000 would be required. The furnishing of the new building had been completed in a way leaving nothing to be desired.

SHAM DOCTORS IN SOUTH LONDON.

IT is eminently satisfactory, both from a public and professional point of view, to observe that coroners and juries are beginning to justly appreciate the dangers arising from the unchecked practice of sham doctors. Without losing sight of the fact that there is no law compelling the employment of registered medical practitioners in cases of illness, it is of the first importance that the public should be protected from the risk of employing quacks, herbalists, and other pretenders of the healing art, under the misapprehension that such persons are real doctors. Fortunately there is a law which, unsatisfactory as it is, may be used to check an abuse, the extent of which in many localities is little dreamed of by the public and is far too easily acquiesced in by the profession. Although in some sparsely-populated parts of the country medical attendance is not within easy access of the sick, and is on this account frequently not sought, by far the largest proportion of the nearly 25,000 uncertified causes of death annually registered in England and Wales arises from the practice of unqualified medical practitioners. As the law at present stands an inquest provides the only machinery for satisfactorily ascertaining the cause of death in such cases, and also whether the relations of the deceased person intentionally and knowingly called in an unqualified in preference to a qualified medical practitioner. The large proportion of uncertified deaths, and by fair inference of irregular medical practice, in South London, compared with the rest of the metropolis, have frequently been referred to in these columns, and two cases publicly reported during the past week fully and usefully expose the manner in which the sick poor are imposed upon by sham doctors. At the Lambeth Police-court a man, who has been practising in the Walworth-road, Newington, pleaded guilty to three distinct charges in respect of offences under the Births and Deaths Registration Act, 1874, and also under the Medical Act, for giving a certificate as a member of the Royal College of Surgeons and an Associate of the Apothecaries' Society. The aggregate fines in respect of the three summonses amounted to £22. In this case the unqualified practitioner placed himself within easy reach of the law by giving a false certificate. Unfortunately, however, this legal offence is avoided by the larger proportion of sham doctors, and although registrars may report uncertified deaths to coroners, and although coroners may hold inquests, and thus fully expose the mischief of such irregular practice, the evil is scarcely held in check.

WANTON CRUELTY UNDER THE GUISE OF SPORT.

Is there any superfluous energy which is not worked off by associations like those for the Obstruction of Scientific Inquiry by the Suppression of Vivisection? If this is not the formal title of the organisation it expresses the idea. A field admirably adapted for the exercise of pity and effective interference offers itself in connexion with the monstrous pastime of pigeon-shooting. We have again and again called attention to these atrocities, committed under the pretence of "sport," and bringing unmerited contumely on the legitimate enterprise of the true sportsman, who would no more be guilty of pigeon-shooting *à-la-mode*, than he would of chasing cats or flying cockchafers with pieces of cotton attached to their legs. There is a wondrous combination of brutality and imbecility in the slaughter of tame pigeons which makes the "amusement" difficult to describe. It has been asked whether a substitute could not be devised. A flight of toy bomerangs, or feathered tops, of the Lowther Arcade pattern, would afford fully as much diversion as the doomed consignment of pigeons sent to be slaughtered for the afternoon's entertainment of the women in satins and sealskins who frequent the places where this hideous cruelty is practised. The only objection to substituting inanimate objects for the present victims would be that inasmuch as the feathered top and the toy bomerang would move, which the dazed and exhausted pigeons often refuse to do, the gallant sportsmen might find it difficult to make a decent score! There are, doubtless, devices by which a fair proportion of hits could be secured, but this we leave to the initiated. Suffice it, in the interests of humanity, as well of the suppression of cruelty to animals, to enter another protest against a practice which is nothing more or less than a wanton burlesque of sport.

THE EXCRETION OF LIME.

MANY investigations have been directed to the determination of the amount of lime excreted in various pathological states, and many observations exist of changes in the excretion. One of the earliest observations was that of Prout, relating to the phosphatic diathesis, which was recognised by the deposit in the urine. Later an increased excretion of earthy phosphates was assumed to exist in many diseases of the nervous system and kidneys, and a diminished excretion in some other diseases. Beneke studied the mode of formation of oxalate of lime in the organism, and Senator has directed attention to the variations in the amount of lime excreted in various conditions. The last contribution to the subject is contained in an article in the current number of Virchow's *Archiv*, by Dr. Schetelig. The method of estimation which he has employed is the precipitation of the lime by oxalic acid; the precipitate was dried and dissolved in hydrochloric acid, and the lime precipitated by soda. The phosphoric acid was estimated by means of acetate of uranium.

The first question to determine was the amount excreted by normal individuals, since the statement of different authorities on this point differ largely, varying from 100 to 500 milligrammes. Experimenting on himself during eight days, the excretion was found to vary from between 350 and 500 milligrammes. It is greatest, like the other solid constituents, in the morning urine, and, when no breakfast was taken, the minimum was found in the urine passed just before the midday meal. Five hours later the quantity was greater; ten hours after the meal it was greater still. The excretion seems thus to bear relation to the material taken at a meal, and to the process of intestinal digestion. In starvation, accordingly, the excretion of lime almost ceases. On two days the midday meal was omitted, and on a third only an extremely small quantity of solid food was taken; the morning excretion of lime fell to an average of 70 milligrammes, and once only 35 milligrammes were noted.

The long delay after food before the amount of lime is increased in the urine makes it probable that it passes through the organism in some other path than, for example, that taken by the haloid salts, which find their way into the urine in a very short time. From a long series of observations the conclusions were drawn that carbonate of lime, even when given in very small quantities and with much water, is quickly absorbed and appears in the urine. The lime-phosphates of meat are, to a small extent, transformed into chloride or directly absorbed, but for the most part pass with the albumen into the small intestine and into the lymphatic vessels, but need the presence of the hydrochloric acid of the stomach for their preparation for absorption. The ingestion of water assists the passage of the lime into the vascular system in a very striking manner. No pathological increase in the excretion of lime could be demonstrated in chronic diseases of the thoracic organs or of the central nervous system, and seems to be improbable. The amount of phosphates in the urine is apparently regulated by the process of intestinal digestion and absorption, rather than by the conditions of the cell-life of the body. The best means of counteracting the effect of the ingestion of lime is the free administration of water and chloride of sodium, or of hydrochloric acid.

"THE SLEEPING GIRL OF TURVILLE."

WE have been favoured by Mr. Henry Hayman, F.R.C.S., of Stokenchurch, with the sequel of the above case, noticed in the issue of the 12th of last June:—"It may be interesting to your readers to know that a change has taken place in the girl. I was called to see her about three weeks ago, and on the occasion of my visit I took her hand in mine, and said to her: 'Ellen, if you know me, and all around me, and everything that is said, squeeze my hand.' This she did *firmly*. I repeated the same words, and she again squeezed my hand. To-day I have visited her again, and have had a conversation with her. She has opened her eyes, and answers every question put to her. She takes plentifully of nourishment many times a day, and she hopes soon to be able to sit up. Her general health, in every respect, is quite regular."

THE ABUSE OF OPIUM.

ATTENTION is once more attracted to the alleged wide-spread abuse of opiates. Some attempt has been made to discredit the medical profession on the score of this evil by attributing the indiscriminate recourse to narcotics to the frequency of their use for medical purposes. The two things have nothing in common. As well might the lazy practice of lying-in-bed be referred to the fact that medical men recommend rest in a recumbent posture during the persistence of most acute diseases. What may be deemed expedient in sickness is not, also and therefore, to be deemed desirable in health. Those who take opiates or quack and advertised remedies for "sleeplessness" habitually, because they have been directed to take them when suffering from special maladies and while under medical treatment, can find no valid excuse for this abuse in the use they plead. It is ridiculous to blame medical men for the drunkenness of the weak-minded, or their addiction to the consumption of "anodynes" and "sleeping-potions." Medical practice cannot be affected by criticism of this class. It is unprofessional to prescribe remedies which are not public property. We have not a word to say in apology for physicians who employ patent medicines or use private formulæ; but whatever a practitioner of medicine believes to be good for his patient he must use, whether the short-sighted blame his judgment or whether they are obliging enough to credit him with the possession of a scientific intelligence. No advantage to public health and happiness is likely to be gained by the promulgation of strictures such as those which have recently found their way into the public press. We mention this matter only to disclaim the slightest thought of being moved by these feeble outpourings of mistaken and misleading sentiment.

THE UNIVERSITY OF EDINBURGH.

THE Matriculation Returns of the University of Edinburgh for 1880, and published under the head of "University Intelligence" in *The Times* of January 4th, are very remarkable. The aggregate number of students who matriculated during the year was 3172, being 316 more than on the previous register. These were divided among the different Faculties as follows: in the Faculty of Arts 1020 students, in that of Divinity 78, in that of Law 440, and in that of Medicine no less than 1634. The nationality of the medical students is interesting. From Scotland there were 679, from England 558, from Ireland 28, from India 112, from different British colonies 204, and from foreign countries 53. Thus 41 per cent. of the students are Scotch, and 34 per cent. are from England. These facts supply material for much speculation. The Scotch nation has long shown its aptitude for the professions. But it looks as if the profession of Medicine is as much in the ascendant now as that of Divinity used to be. In estimating, however, the small number of Divinity students as compared with those of the other Faculties, it is necessary to remember that Scotland is now theologically a very divided country, and that the various churches have all their own theological schools, with often very able professors. It would be foolish to attribute the growing popularity of the Scotch schools, and notably that of Edinburgh, to anything so much as the growing efficiency of the work they do, of the laboratories and hospital which have been erected and furnished, and the devotion and ability of the professors, who are rewarded for making teaching the main object of their lives. The medical legislation of 1858 has doubtless had something to do with it by introducing reciprocity of practice, and making the degrees of the University valid legal instruments for purposes of practice all over the British dominions. But too much must not be attributed to this circumstance; for, as Professor Turner, in an address lately published in our columns, showed, the fame of one Scotch professor of anatomy (Munro Secundus) attracted a class of no less than 436 a hundred years since, when the population of Scotland was about a third of what it is now. Only a small proportion of those studying in the Scotch Universities take degrees. In the year 1880, of the 1634 medical students (many of course students in the first and second years only), 153 took degrees—viz., 29 that of M.D., 129 the double degree of M.B. and C.M., and 5 that of M.B. only. The present demand on the teaching of the Scotch Universities was not reached in a steady and progressive way. After the new regulations for degrees resulting from the appointment of a Royal Commission in 1858, including amongst other things a preliminary examination in Arts, conducted by Arts professors, a great falling off in students took place, so that in 1868 and 1869 the total number of medical students fell to 403. It has risen since by "leaps and bounds," and must tax all the resources of the University and its teachers.

UNQUALIFIED PRACTITIONERS.

MR. PAYNE, the Southwark coroner, commented lately very properly on the facts connected with the death of Mrs. Martha Lersty, of Southwark Bridge-road, who called in a person who represented himself to be Dr. Harding, of Great Suffolk-street, but who was afterwards discovered to be a chemist named Wardley. Mr. Payne said several cases had come under his notice as coroner in which Wardley had passed for "Dr. Harding," whose name was on his door. He had reprimanded him. In one case the jury had found that Wardley's conduct had accelerated, if not caused, death. The coroner intimated that he had brought the facts under the notice of the General Medical Council, but, of course, "in spite of this the practice was still continued." Is there any other country in which such misrepresentation as this is allowed to go unchecked? Impositions practised on people in health, and with their wits about them, is a crime that commands the attention of police and law courts; but imposture committed on dying people is, it seems, nobody's business. Mr. Payne has at any rate discharged his duty as a coroner in exposing the great scandal, which exists on an enormous scale.

THE ROYAL COLLEGE OF PHYSICIANS, AND SIR WILLIAM GULL AND DR. PAVY.

THE profession naturally looks for some adjudication of the questions of etiquette and procedure which were raised in connexion with the inquest held some months ago on a patient who died in Guy's Hospital. The matter was, it will be remembered, referred to the Censors' Board of the Royal College of Physicians for decision. The statements of Dr. Pavy and Sir William Gull are, we believe, now before the Board, and it will be agreeable to the feelings and interests of all parties that the deliberation shall be brought to a satisfactory issue without needless delay.

GLASGOW ROYAL INFIRMARY.

IN the course of a letter addressed to the public, containing an appeal for more liberal support, Mr. Wm. McEwen states that in the above institution "treatment is much more expensive now than formerly; as looking back to the time when the new surgical hospital was opened I find the expenses then were only about £14,000, as against £24,000 now, owing chiefly to large increase in general and working staff, absolutely necessary, with better wages and more generous diet both to patient and staff, but still at a rate of cost less than in any similar hospital. Against this increased cost, however, may be mentioned that 646 patients died in 1863, 763 in 1864, and 740 in 1865. In 1879 the number who died was 463, and last year 477. It may not be right to associate these as cause and effect, but still it is a remarkable fact, that with the increased care and more expensive treatment every year the mortality seems to come down."

PAYING PATIENTS AT ST. THOMAS'S HOSPITAL.

THE Governors of St. Thomas's Hospital have at length announced that they will be prepared, in the course of the present month, to receive into St. Thomas's Home persons of the upper and middle classes who are able and willing to pay for the benefits of medical attendance and nursing. Two wards in one of the end blocks, away from the rest of the hospital, have been set apart for the reception of these patients, and a resident medical officer has been appointed to take exclusive charge of these patients for their ordinary treatment, though each patient will have the option of employing at his or her expense any legally qualified practitioner in consultation with the resident medical officer. Though the Home, like the Hospital, is controlled by the governors, the medical administration will be wholly distinct from that of the hospital. The honorary medical and surgical officers of the hospital are, as regards the Home, on the same footing as any other legally qualified medical practitioner. The honorary officers were elected to administer the medical charity, and have steadily and persistently stood aloof from the proposal of introducing paying patients into the hospital buildings. As it is, the wards that have been prepared for the reception of paying patients have not been used for many years in consequence of lack of funds, are approached by a separate gate and entrance, and are consequently distinct from the hospital as a charitable institution. On the other hand, the governors, apparently pleased with the idea of receiving paying patients, have resolved to admit into the ordinary wards patients who, though poor, can yet afford to contribute something towards the cost of their maintenance. No difference will be made as regards attendance and nursing between these patients and those who receive purely gratuitous aid.

THE RED CROSS IN THE RUSSO-TURKISH WAR.

A REPORT has been published by the Russian Red Cross Society showing the part played by this Society during the Russo-Turkish War of 1877-78. It appears that the Society established 13,120 beds, and that a total of no less than 24,973 were founded by voluntary agencies in conjunction with the Red Cross Society. The Society, moreover, gave succour to 116,296 patients, among whom were 1238 officers. The deaths of patients under their care amounted to 2863. The Society's staff consisted of 300 medical men, including sub-surgeons, and 1214 attendants.

PUBLIC LAW AND THE PLAGUE OF SMALL-POX.

ONLY those who are behind the scenes know how heavily the first warning notes of a great epidemic of small-pox are falling upon the ear of those who have ears to hear. Meantime, it is pitiable to see how helpless those public bodies are to whom the public naturally look for prompt measures of isolation and revaccination. Dr. Brewer, the President of the Metropolitan Asylums Board, in a letter to *The Times*, shows how he and his colleagues are paralysed in using a great small-pox hospital, for fear of incurring a liability to personal damages to the amount of £20,000. The Local Government Board has, as yet, given no sign in its whole history that it realises the gravity of its responsibility as a sanitary authority.

ZULU WAR MEDAL.

WE understand that the medal for the Zulu war is now in course of distribution. We recommend any medical officers who may be entitled to but have not yet received it, to communicate their present address to the Director-General, A.M.D., with a request that their medal may be forwarded to them.

THE *Publishers' Catalogue* (Messrs. Sampson Low, Searle, and Rivington) contains, in accordance with its usual custom, an Analytical Table of the Books published in the past year. By this table it appears that during 1880, Medical and Surgical literature has been enriched by the addition of 202 volumes, fifty-four being new editions, as compared with 189 (53 new editions) in 1879. It is interesting to note that in point of number of works issued, of the whole fourteen sections into which the subjects of the books are divided, only three—namely, those of "Law, Jurisprudence, &c.," "Poetry and the Drama," and "Belles Lettres, Essays, &c."—fall below that of "Medicine and Surgery." The highest place, numerically, is occupied, as perhaps might have been expected, by the section "Theology and Sermons."

THE following resolutions were passed at the meeting of the Society of Medical Officers of Health held on the 17th of December, 1880, Dr. Bristowe in the chair:—1. "That in the opinion of this Society it is desirable, having regard to the more effectual prevention of the spread of zymotic disease by the agency of milk, that the special sanitary supervision and inspection of cowsheds, dairies, and milk-shops, should be entrusted by the local authorities to the medical officers of health, and the sanitary inspectors of the respective districts. 2. That in the opinion of the Society all cases of uncertified deaths should be reported by the local registrar of births and deaths to the coroner, who should, when there is no *primâ facie* ground for holding an inquest, direct each case to be investigated and reported on to him by a registered medical practitioner. The Society are also of opinion that there is no special reason why such investigation should devolve on the medical officer of health as any necessary part of his ordinary duties."

THE Council of the Faculty of Physicians and Surgeons of Glasgow have agreed at their next meeting in the beginning of February to consider any applications which may have been made for the position of Faculty Lecturer for 1881. The lectureship, which is open to the whole profession, was established several years ago, mainly for the purpose of giving encouragement to original research. The subject may lie in any department of medicine, theoretical or practical. The lectureship has been held in former years by Dr. B. W. Richardson and Professor M'Kendrick.

THE Lettsomian Lectures will be delivered by Sir Joseph Fayrer, at the rooms of the Medical Society of London, Chandos-street, Cavendish-square, on Jan. 10th and 24th, and Feb. 7th, at 8.30 P.M. The subject will be Tropical Dysentery and Diarrhœa.

THE death is announced of Dr. Julius Vogel, from cardiac rupture. The deceased was director of the Medical Clinique and Professor of Special Pathology and Therapeutics at Halle.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

Faversham (*Rural Sanitary District*).—This inquiry, which was conducted by Mr. W. H. Power, was called for in consequence of an outbreak of diphtheria in the parish of Herne Hill in the autumn and winter of 1878-79. But before the inquiry could be entered upon the outbreak had come to an end, and so long a period had elapsed since the cessation that it was found impracticable to recover such details as would help to a satisfactory elucidation of the circumstances under which the outbreak had occurred. The outbreak, as is so often the case in diphtheria, had been associated with much throat illness, to which various names had been given, extending over a much wider area of country than that in which diphtheria had been observed. The interest of the report rests in the account it gives of the state of sanitary administration in the district, which formed a second subject of inquiry. This district had been previously under the observation of the Local Government Board, and this portion of the inquiry was directed to ascertain what changes had taken place in its sanitary administration since an earlier inspection made by Mr. Power. The more recent inspection showed that a very distinct advance had been made, particularly in privy construction and management. It showed also the curious inconsistencies which attach to our practice of self-government in these matters. The town of Faversham is partly in the rural sanitary authority's district. The rural sanitary authority has adopted excellent by-laws regulating the erection of new buildings; the urban sanitary authority has no by-laws on this subject. It happens, therefore, that the new houses built in the part of the town under the rural sanitary authority's management fulfil, as regards ventilation of drains, position, construction, lighting and ventilation of closets, those requirements which modern enlightenment have demanded, while in the portion of the town under the urban sanitary authority's management, the new houses fall very far short of a proper standard in most, and sometimes in all, of these particulars. In the same town one sanitary authority is doing its best to avoid for the future those evils of house-construction which underlie most of our unwholesome conditions; the other sanitary authority encourages the perpetuation of these very evils, fostering the growth, on the one hand, of the very mischiefs which, on the other, it is presumably endeavouring to suppress.

Enfield (*Urban Sanitary District*).—This is a report of an inquiry, made by Dr. H. F. Parsons, for the Local Government Board, into the prevalence of "fever" at Enfield and the general sanitary condition of the urban district. It furnishes anotheri nstructive and somewhat detailed illustration of the deplorable insanitary conditions under which much of the cottage property has been erected in the populous suburbs outside the metropolitan area and presents a painful example of the slovenliness, negligence, and want of foresight of the local sanitary administration. Enfield has not neglected to expend certain sums on sewerage and water-supply, but that careful supervision of the district which is requisite to ensure that both the sewerage and the water-supply answer their purpose and that the requirements not only of the statutory law, but also of their own by-laws, are carried out is egregiously neglected. Moreover, these by-laws are quite inadequate to deal effectively with the speculative builders who are seizing upon the district to meet the flow into it of residents from the metropolis. The "fever" (enteric) is one of the evils which follow in the track of the infamous construction which too surely marks the work of the speculative builder when his proceedings are not most stringently regulated.

Clitheroe (*Rural Sanitary District*). — This district lies partly in Yorkshire, partly in Lancashire. Prevalence of diphtheria in a part of the district first took Dr. Airy into it, but his visit there resolved itself into an inquiry into the general sanitary state of the district. The bulk of the population, not exceeding 3000 in number, is engaged in the grazing farms which chiefly cover the district, and the villages and hamlets have the usual characteristics of unreformed rural places. The occupants, as a rule, however, are fairly well housed, but exposed to difficulties of water-supply, and imperfections of drainage and of filth disposal, such as are commonly found in such districts where the sanitary authority is a name and little more. The fact that Dr. Airy has been called upon to make a report of this sort is an indication of the mere nominal character of the local sanitary administration.

Millbrook.—Millbrook is a village in the rural sanitary district of St. Germans, Cornwall. It is situated at the head of a tidal creek communicating with the Hamoaze, and is a local health-resort. Hence, probably, its present condition; for the parochial committee of the rural sanitary authority, in public meeting assembled, does not hesitate to imply that it is of more importance to the villagers to retain their seasonal visitors than to amend their village. And the sanitary condition of this is such that if it were noised abroad (as it must be if attempts at improvement are made), "lodgers" would be frightened away. Now, this so-called "health-resort" (!) is about as abominable sanitarily as can readily be conceived; its tidal creek a big, stinking sewer, and its general arrangements for drainage and water-supply as foul as could well be. Enteric fever is endemic there, and if the history of its visitors for several seasons could be obtained, we have little doubt that it would be found that a large proportion of them carried with them when they returned home, disease, not health, obtained from their sojourn. A more than usually serious outbreak of enteric fever last year appears to have been brought to the notice of the Local Government Board, and Dr. Ballard was directed to investigate it. It is highly probable that this outbreak was caused by the dissemination of the infection of the disease in the milk of a dairy, kept under singularly slovenly and unwholesome conditions. In fact, Millbrook instead of being a "health-resort," is simply a "disease-trap," as so many so-called "health-resorts" unfortunately are.

SMALL-POX HOSPITAL ACCOMMODATION IN LONDON.

A deputation of the Metropolitan Asylums District Board, headed by the chairman, Dr. Brewer, had an interview with the President of the Local Government Board, Mr. Dodson, on the 30th ult., on the subject of small-pox hospital accommodation in the metropolis at the present time. The existing accommodation is practically occupied, the Asylums Board could not undertake the responsibility of purchasing new sites for hospitals while the appeal in the Hampstead Hospital case was pending, Hampstead Hospital was closed to them, further accommodation was wanted,—what were they to do? Would the Local Government Board assent to the Asylums Board providing accommodation for seventy additional patients on the site at Deptford? Mr. Dodson demurred to this proposition, observing that already there was a large number of patients at Deptford, and added that the Parliamentary Committee on the Hampstead Hospital had, he believed, expressed an opinion against the congregation of many small-pox patients on one spot. He admitted the difficulty arising from the appeal in the Hampstead Hospital case, and he thought that if the epidemic increased even seventy beds added to the present accommodation would be insufficient. He sympathised with the Asylums Board in their difficulty, saw that whatever was done by them must be done *immediately*, and—would consider the question. In other words, the Asylums Board look to the Local Government Board in their difficulty, as being mainly responsible for its having happened, and in the "emergency," to use Mr. Dodson's word, find the Board unprepared to advise them at the moment, although the question at issue has been agitating people interested in it any time the last six weeks! A more striking confirmation of the observations we ventured to make on the false position the different metropolitan authorities and the Central Authority have to each other on this subject of small-pox could not well be conceived.

Since this deputation Dr. Brewer has communicated to *The Times* of Jan. 5th, at the request of the Asylums Board, the following important statement of the position in which the Board is at present placed:—

"Sir,—At a meeting of the Asylums Board yesterday evening, convened for the purpose of making provision for the daily increasing number of persons afflicted with the epidemic of small-pox which is marching on the metropolis from the south-east, and sporadically present in the south-west and districts apparently unconnected with each other, the managers urged their chairman to communicate to the public, through the Press, that, while they are even increasingly anxious to protect the metropolis by the timely isolation of the infected and the effectual vaccination of those liable still to the worst forms of the disease, they are unable to enter the market for new sites or to appropriate any additional building for the isolation of the infected, because an injunction rendering the managers severally and jointly liable to a penalty of £20,000 is hanging over them if they again avail themselves of the Hampstead site, bought and fitted up by them expressly for the purpose of protecting the north and north-west of the metropolis, and constituting an integral part of the original design for providing protection to the whole of London.

"Until the final Court of Appeal has determined whether the 'public policy' expressed by Gathorne Hardy's Act of 1867 did or did not warrant, through the authority of the Local Government Board, the managers to purchase sites and erect buildings for the isolation of people affected with contagious disease of the humbler classes in such localities in the metropolis as the Government Board deemed best calculated to secure the object contemplated by the Act, it must be obvious to your readers that we are paralysed, so far as prospective action is concerned. It must not hence be conceived that the managers abate one jot of their anxiety to arrest the coming calamity: no men know better what is the liability of the 200,000 unvaccinated persons among a mass of well-nigh four millions, packed within an area of 75,362 acres. The sufferings to which we minister quicken, and not deaden, our sympathies; and while we are using every bed available and every means within our power to ward off or to provide for the needs which are pressing upon us, we feel ourselves bound to state frankly what it is which limits our means and why we are forced to declare that we are not responsible for the suffering and mortality we must perforce anticipate, but cannot adequately provide for or guard against."

ANTI-VACCINATIONISTS' PARLIAMENTARY RETURNS.

Another of the series of Parliamentary returns called for by Mr. Hopwood, M.P., in the interest of anti-vaccinationists, has just been published under the signature of the Registrar-General. It relates to the thirty-two years 1847 to 1878, and is on the whole a valuable contribution to the statistics of small-pox and vaccination, especially as by the addition of information beyond what was asked for, the public is guarded against the erroneous and mischievous conclusions which were drawn from a previous and somewhat similar return. We commend the figures in this return to the attention of Mr. P. A. Taylor, M.P., who, it may be presumed, is preparing his indictment against compulsory vaccination. The proportion of fatal cases of small-pox occurring under one year of age in England and Wales, to the fatal cases at all ages, which averaged 25·5 per cent. in the six years 1847–52, did not exceed 12·9 per cent. in the six years 1873–9. The most marked change of proportion, however, appears at the ages between one and five years; at this group of ages the proportion declined between these two periods from 44·4 per cent. to 12·8 per cent. It is for those who deny the influence of vaccination upon small-pox mortality to assign some other reasonable explanation of the change in the proportions of small-pox mortality occurring at different ages since vaccination was made compulsory. The increase in the proportion of adult fatal cases of small-pox in recent years is a natural consequence of the marked decline of deaths from this disease occurring among children. It should, moreover, not be forgotten that the average annual death-rate from small-pox at all ages in England and Wales since compulsory vaccination was enacted has been less than half that which prevailed during the years of civil registration which preceded the passing of the first Vaccination Act.

The other point on which the present report throws useful light is the asserted increase of infant mortality since vaccination became more general. In a previous return called for by Mr. Hopwood tables showed that the deaths of infants from syphilis, scrofula, tabes mesenterica, skin diseases, erysipelas, phlegmon, bronchitis, diarrhœa, and atrophy and debility, including premature birth, had, in the aggregate, steadily increased during the past forty years. This fact gave rise to the misstatement that vaccination had caused a great increase in the rate of infant mortality. In the present return, in order the more effectually to guard against a repetition of this misapprehension, the Registrar-General has added a column showing the proportion of infant mortality from all other causes, demonstrating conclusively that the increased mortality from bronchitis, diarrhœa, syphilis, and scrofula, from whatever causes it may be due, is more than counterbalanced by the decline of mortality from other diseases. During the six years 1847–52 preceding compulsory vaccination, the proportion of deaths of infants under one year, from all causes, averaged 156 per 1000 births; whereas in the six years 1873–8 (the most recent dealt with in the return) the average annual proportion did not exceed 149 per 1000. How far improved or more precise diagnosis of infantile diseases may be the cause of the increased number of deaths recently attributed to bronchitis, diarrhœa, syphilis, and scrofula, it is needless here to inquire. It is, however, eminently satisfactory to find that the average rate of infant mortality is now five per cent., or one-twentieth, less than it was before vaccination became compulsory.

SCARLET FEVER IN SUNDERLAND.

The Health Department of the Sunderland Corporation have published a report by Dr. Yeld, their medical officer of health, on the epidemic of scarlet fever, now in the fifth year of its duration in the borough. He attributes the propagation and spread of the disease to the following causes:—(1) The non-isolation of the first case appearing in a family; (2) the indiscriminate intercommunication of the healthy with the sick; (3) children being allowed to attend school and public places of resort during the convalescent stage of the disease, and very frequently wearing the same clothes that they wore during the period they were suffering from the disease; (4) children attending school from infected houses; (5) children being allowed to attend funerals, and even to view the bodies, of those who have died from the disease; (6) the transmission of infected clothing and bedding from one house to another; (7) the want of early information of the outbreak of the disease in any house being forwarded to the Local Sanitary Authority, in the vast majority of cases the earliest information received being that from the registrar of deaths. Isolation, of all other means, is regarded by Dr. Yeld as the best for arresting the spread of infectious diseases; and he has some observations on this subject which we have little doubt will prove advantageous to his Health Committee. Sunderland, it appears, has an infectious disease hospital, provided on account of the small-pox epidemic of 1871, but which has not been as much used as it might have been since, particularly in view of arresting the spread of an infectious disease at the beginning. This, Dr. Yeld states, has not been from want of desire on the part of the sanitary authority, but on account of medical men and heads of families not having taken advantage of the boon offered them. "There cannot be a doubt," he adds, "that had even the limited accommodation of the House of Recovery been taken advantage of two or three years ago, the spread of scarlet fever, and its consequent fatality, would have been very materially diminished; neither is there any doubt that had the accommodation for the patients been found too small, the committee should have taken the matter in hand, and dealt with it in a practical, disinterested, and satisfactory manner." Dr. Yeld urges the Health Committee to recommend to the Town Council to obtain powers from Parliament compelling the notification of infectious diseases, such as have been obtained by several other municipalities.

SANITATION IN LEEDS.

The health of Leeds, judged by the monthly reports of Dr. Goldie, its medical officer of health, has recently been unusually satisfactory. According to the last monthly report issued, it appears that the annual death-rate in that borough during the four weeks ending the 27th of November did not exceed 19·9 per 1000, against 25·6 in the corresponding period of 1879. Infant mortality and the death-rate from the principal zymotic diseases were exceptionally low. It is to be regretted that Dr. Goldie persists in giving so-called rates of mortality at different groups of ages per 1000 of persons living at all ages. These rates for comparative purposes are not only useless, but frequently lead to entirely erroneous conclusions, as this method takes no account of the varying age proportions of the populations in different towns or in different parts of the same town. Useful rates of mortality at different groups of ages can alone be calculated with reference to the numbers living at each such group of ages. Leeds, like Salford and other large towns, has had its threatenings of small-pox, and Dr. Goldie seriously calls the attention of his sanitary authority, the Town Council, to the dangerous position of the town in consequence of its being unprovided with special hospital accommodation for the isolation of cases of this disease. It appears that one of the Local Government Board inspectors has recently made a special representation to the Town Council on the subject. The increased prevalence and fatality of small-pox in London adds considerably to the danger of infection incurred by all large towns in intimate railway communication with the metropolis. It is satisfactory to note that the 487 deaths registered in Leeds during the four weeks under notice included but eleven uncertified causes of death; these give a proportion of 2·3 per cent., against 4·0 per cent. in the three months ending September last.

DIARRHŒA IN WIGAN.

An elaborate report has been submitted to the Sanitary Committee of the Corporation of Wigan, by Mr. Barnish, their medical officer of health, on the prevalence of diarrhœa in the borough during the third quarter of the year. In this report Mr. Barnish shows that the disease is mainly confined to a particular season of the year, that it chiefly affects young children, is more especially a disease of crowded towns, and is mostly confined to the poorer inhabitants. High atmospheric temperature holds, he thinks, the first place in conducing to the disease, and after atmospheric temperature, in exercising the most important influence as a concurrent cause, he would place the artificial feeding of infants. He refers to the *dark* surroundings of life in the close courts and streets of Wigan as contributing also to the result. It would appear, however, that since Wigan began to abolish the old-fashioned privy, or midden closet, and its foulness, and has substituted a pail-closet, the mortality from diarrhœa has distinctly decreased in the town and is, Mr. Barnish believes, decreasing; increased cleanliness of the surface of the courts, back-streets, and alleys helping to this result.

Here is a curious instance of the "Imperial Julius dead, and turned to clay," &c., serving to point a poor-law moral at the expense of a medical officer. At a recent meeting of the St. George's-in-the-East Guardians, complaint was made that the medical officer of the schools had of late been irregular in attendance, his place being supplied by substitutes. Whereupon a member observed that he had been reading in the course of the day of the death of "George Eliot," and noted that a regret was expressed that Dr. Andrew Clark had not been first summoned to her bedside, and so, probably, a greater chance of saving her life secured. He applied this to the children in these schools, of whose welfare they were the guardians, and would ask if this irregularity of the medical officer could be permitted to go on indefinitely when his presence or absence might involve the difference of life and death to a sick child. The medical officer should feel highly gratified that his individual services in the schools are ranked so highly.

Mr. Wynter Blyth, the successor of the late Dr. Whitmore as medical officer of health for Marylebone, has issued his first monthly report. It will chiefly attract attention for two suggestions he makes; the first (somewhat prematurely, it is to be feared) for preventing the spread of small-pox and scarlet fever by smearing the patients from head to foot with glycerine, and placing a bottle of ice-cold water a little before the mouth, and, in view of typhoid fever, for heating all milk to at least 212° F. before it is sold. Mr. Blyth states that he has submitted his first suggestion "to the ordeal of exact experiment, so far as the nature of things admits," whatever that may mean, and he uses these words in reference to his second suggestion, "It is time for the public to demand from the milk trade *germ-free* milk," as if the evidence as to the *germs* were as clear as the evidence as to excess of water in milk.

It appears that the Urban Sanitary Authority of Pontypridd is considering a scheme of laying down a system of sewers for slop water only, providing for excremental matters by dry-ash- or earth-closets. The ratepayers, or a section of them, take exception to this; and at a recent public meeting Dr. Hunter, a medical practitioner of twenty years' standing in the town, took objection to any scheme of drainage which did not include provision for the whole of the Rhondda Valley and its increasing population. A resolution was passed at this meeting requesting the Urban Sanitary Authority to defer the consideration of their scheme for three months, and to call for other schemes adapted for the requirements of the district.

An application made by the Sanitary Authority of Warrington for the compulsory removal of a patient to the fever hospital on the ground of imperfect isolation, has been refused by the magistrates. The medical officer of health and the medical man in attendance differed as to the degree of isolation which had been secured to the patient in a seven-roomed house. It was urged that the medical officer of health, having given a certificate to the effect that the patient should be removed, the magistrates had no choice, under the Local Act, but to give the order for removal, but the magistrates held the case was not made out. A case was granted for the Court of Queen's Bench.

The Right Hon. James Stansfeld, M.P., in an address delivered at the recent Poor-law Conference in Leeds, thought it was a mistake that boards of guardians should be under no control, and expressed his opinion that the central authority ought to counsel, inform, enlighten, and guide, and he believed the local authorities would willingly and gratefully respond to such policy. Hitherto it has been a case of the blind leading the blind with a vengeance, and local authorities, Poor-law and others, are beginning dimly to understand this.

Chesham has got into trouble for prematurely closing its infectious disease hospital. The medical officer of health says that the existing hospital is unfit to be occupied by sick persons in cold weather, and the sanitary authority hesitate to make it fit or to provide another and better hospital. Meanwhile the need for a hospital continues.

We understand that W. Meymott Tidy, M.B. Lond., has resigned his post as Public Analyst for the County of Essex.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Mainly owing to delay of registration in the previous week, due to Christmas-day falling on Saturday, the registered mortality in the principal English towns showed an increase last week. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5035 births and 3408 deaths were registered last week. The births were 150 below, while the deaths exceeded by 133 the average weekly numbers during 1879. The deaths, owing mainly to the cause above stated, showed an increase of no less than 739 upon the exceptionally low number in the previous week. The annual death-rate, which had steadily decreased from 22·1 to 18·6, rose last week to 23·7. The lowest death-rate in the twenty towns last week were 15·7 in Newcastle-upon-Tyne, 15·9 in Portsmouth, 18·8 Sheffield, and 19·3 in Bradford. The rates in the other towns ranged upwards to 27·2 in Salford, 28·0 in Oldham, 29·5 in Wolverhampton, 29·8 in Liverpool, and 30·3 in Nottingham. During the thirteen weeks of the quarter just ended the death-rate in the twenty towns averaged only 21·5 per 1000, against 25·0 and 24·2 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 375 and 342 in the two preceding weeks, rose to 398 last week; they included 137 from scarlet fever, 84 from measles, 72 from whooping-cough, and 48 from fever, principally enteric. The annual death-rate from these seven diseases averaged 2·8 per 1000 in the twenty towns; it ranged from 0·7 and 1·0 in Plymouth and Newcastle-upon-Tyne, to 5·5 and 5·8 in Wolverhamptom and Sunderland. Scarlet fever showed the largest proportional fatality in Sunderland, Bristol, Oldham, Wolverhampton, and Norwich; fever, principally enteric, in Wolverhampton, Norwich, and Leicester; and whooping-cough in Leeds, Hull, and Sunderland. Small-pox caused 17 more deaths in London, whereas no fatal case of this disease was recorded in any of the nineteen provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 380 in the nine preceding weeks, further rose to 440 on Saturday; this was a larger number of cases than has been under treatment in these hospitals at any time since the end of June, 1878. The number of new cases of small-pox admitted to these hospitals, which had been 132, 76, and 65 in the three previous weeks, rose to 146 last week. On Saturday last 28 patients were also under treatment in the Highgate Small-pox Hospital, corresponding with the number at the end of the previous week.

The deaths referred to diseases of the respiratory organs in London, which had been 307 and 290 in the two preceding weeks, rose to 353 last week, which were, however, no less than 189 below the corrected average number in the corresponding week of the last ten years; 218 were ascribed to bronchitis, and 82 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·0 per 1000 in London, 6·0 in Liverpool, and 5·9 in Salford.

In the twenty towns last week the causes of 107 deaths were not certified, either by a registered medical practitioner or by a coroner, being equal to 3·1 per cent. of the total deaths. The proportion of uncertified deaths did not exceed 1·7 per cent. in London, whereas it averaged 4·5 per cent. in the nineteen provincial towns. No uncertified deaths were registered either in Bristol or Nottingham; while their proportion was largest in Salford, Oldham, Sheffield, Hull, and Sunderland.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate last week averaged 22·5 per 1000, against 19·9 and 20·8 in the two preceding weeks; this rate was 1·2 below the average rate in the twenty large English towns. The rates in the eight Scotch towns last week ranged from 19·1 in Paisley, and 19·5 both in Edinburgh and Perth, to 25·2 and 25·8 in Dundee and Leith. The deaths referred to the seven principal zymotic diseases in the eight towns, which had been 80 and 92 in the two preceding weeks, were 92 last week, and equal to an annual rate of 3·7 per 1000, against 2·8 in the twenty large

English towns. In the eight Scotch towns the zymotic death-rate last week ranged from 1·0 in Aberdeen to 4·4 and 4·8 in Leith and Glasgow; no deaths from any of these zymotic diseases were returned in Perth. The fatal cases of scarlet fever, which had been 17 and 29 in the two preceding weeks, were 30 last week, of which 12 were returned in Glasgow, 12 in Edinburgh, and 3 in Leith. Eight of the 12 deaths from diphtheria were returned in Glasgow, as well as 6 of the 7 deaths referred to "fever," which includes typhus, enteric, and simple continued fever. The 23 deaths from whooping-cough included 17 in Glasgow, and showed a further increase upon recent weekly numbers. The annual death-rate from acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) was equal to 5·9 per 1000 last week in the eight Scotch towns, against 4·2 in London; the highest death-rates from these diseases in the eight Scotch towns occurred last week in Aberdeen, Dundee, and Paisley.

HEALTH OF DUBLIN.

The registered mortality in Dublin showed a further increase last week. The annual death-rate from all causes in the city, which had been equal to 25·9 and 27·0 in the two preceding weeks, further rose to 35·8 last week. During the thirteen weeks of the quarter just ended the death-rate in the city averaged no less than 32·6 per 1000, against 20·9 in London, and 21·8 in Edinburgh. The 216 deaths in Dublin last week showed a further increase of 53 upon the numbers returned in the two previous weeks; they included 27, or rather less than 13 per cent., which were referred to the seven principal zymotic diseases, and 6 more than the number in the previous week. Of these 27 zymotic deaths, 10 resulted from fever (typhus, enteric, and simple), 9 from scarlet fever, 6 from whooping-cough, and 2 from measles. The annual death-rate from these zymotic diseases was equal to 4·5 in Dublin, against 2·8 in London, and 4·1 in Edinburgh. The 10 deaths referred to fever in Dublin last week showed an increase upon recent weekly numbers, and were equal to an annual death-rate more than five times as high as the average rate from the same cause in the twenty large English towns last week. The fatal cases, both of scarlet fever and of whooping-cough, also showed an increase in Dublin last week. The deaths both of infants and of elderly persons only slightly exceeded the numbers returned in recent weeks.

THE AMERICAN CENSUS—ST. LOUIS.

Between defective registration of births, deaths, and marriages and doubtful census returns, American vital statistics are not yet held in much repute by statisticians. The rates of mortality which, according to official returns, are reported to prevail in the majority of the large American cities are incredibly low, so low as to forbid their acceptance as being even approximately correct. The rapid aggregation of town populations in America places great difficulties in the way of estimating their numbers in inter-census years, and in America, as in England, a census is only taken once in ten years. In England once in ten years the enumerated numbers, however, supply trustworthy figures as a basis for the calculation of vital and mortal statistics; while in America census numbers are not accepted as trustworthy, even by the local authorities, and when the counted numbers are not large enough to satisfy the general desire for big figures, it is not unusual to hear of clamour for re-enumeration. The city of St. Louis is a notable example of the difficulties which surround the preparation of trustworthy statistics for American towns. We have somewhat recently commented upon the untrustworthy mortality statistics officially published for this city, and the results of this census supplies a useful corroboration of the justice of our remarks. In 1860 the population of the city of St. Louis was estimated at 160,773, which had increased to 310,864, according to the government census, in 1870. In 1878 exaggerated ideas prevailing as to growth of the city in recent years, we were told officially that the estimated population by enumeration was stated to be 503,000. Since 1878 the population of the city has been taken as half a million, upon which all rates of mortality have been calculated. We have before us the summary for the year 1879, which gives the rate of mortality as only 12·3 per 1000; this alone should have suggested that the population was over-estimated, more especially as it appears that no less than 30·2 per cent. of the deaths from all causes were due to zymotic diseases. The first report of the population of the city enumerated at the recent census gave 324,196, but so dissatisfied were the authorities with this number that a re-enumeration has since been completed, which raises the population to 351,275. Even this number very far from satisfies the expectations of the city, although there is considerable rejoicing at this gain of 26,719 in the population. By using this number the death-rate in 1879 becomes 17·5 instead of the 12·3 officially reported, but even this appears to be too low a rate when it is remembered that 30·2 per cent. of the deaths were from zymotic diseases. It is impossible to guess whether we have yet had the last census of St. Louis for 1880, but if the figures given by the latest enumeration be accepted as approximately correct, it still seems more than probable that the death-rate is understated, probably through imperfect registration of the deaths. Vital statistics are now attracting considerable attention in America, and we are entitled to hope that ere long they will be rendered more trustworthy than they are at present. Improved system of registration has already been adopted in some of the States, but it is not so easy to devise safe precautions against the falsification of census returns for the purpose of flattering local aspirations for greatness.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

SCIENCE AND SANITATION.

A recent number of the *Journal of Science* contains an article on the "Sanitary Millennium," which betrays a very shallow acquaintance both with its subject and with the true bearing of the statistics discussed. The article professes to be a review of a work by John Parkin, M.D., entitled "Epidemiology, or the Remote Cause of Epidemic Diseases in the Animal and in the Vegetable Creation," but is made the excuse for enunciating a disbelief in the "filth" origin of so-called zymotic diseases, and in the efficacy of vaccination as a protection from small-pox. The *Journal of Science* adjudges Dr. Parkin "perfectly successful in disposing of the two most popular theories—the dirt doctrine of the sanitary reformers and the notion of contagion." The arguments by which vaccination is sought to be discredited are the thread-worn arguments which anti-vaccinationists repeat *ad nauseam*. We are reminded that, notwithstanding the more general adoption of vaccination, the fatality of the three small-pox epidemics in 1857–8–9, 1863–4–5, and 1870–1–2 showed successively a steady increase; no reference is, however, made to the fact that the average death-rate from small-pox since vaccination was made compulsory is just half what it was during those years prior to that legislation of which we have record. The steady proportional increase of the vaccinated among the victims of small-pox during the past half-century is also quoted as difficult to reconcile with the orthodox theory that vaccination is a safeguard against small-pox.

The assertion made by unscientific anti-vaccinationists, to the effect that small-pox is spread and distributed by vaccination, is in a measure adopted, regardless of the well-known fact that vaccination could as soon produce small-pox as measles could be caught from scarlet fever. In ridiculing the theory that the only cause of zymotic disease is dirt, our scientific contemporary asks, with reference to modern attempts at sanitation: "Have we not spent 300,000,000 of money in carrying out these teachings and in paying the fees of our teachers?" As an example of the futility of sanitary expenditure, Manchester is alluded to, and we are asked to believe that the death-rate in that city in 1811 did not exceed 13·5 per 1000, in order to show that, "in spite of all our modern sanitary reforms, the death-rate of the city has increased to more than double its amount in 1811." Manchester should not be quoted as an example of the success or failure of sanitary expenditure, as that city has scarcely kept pace with the other large cities of the United Kingdom in the energetic prosecution of sanitary progress. It is, however, beyond dispute among those acquainted with the history and mortality statistics of Manchester, that the sanitary condition of that city is very different from what it was at the beginning of the century, and that the death-rate as faithfully reflects the improvement which has taken place as that which is still needed. Whatever may be the authority for the statement that the rate of mortality in Manchester, in 1811, did not exceed 13·5 per 1000, we must absolutely decline to accept this figure as correctly representing the average death-rate of that city seventy years ago. If this article had not found place in the columns of a journal which professes to represent science, we should have found it hard to accept, as seriously intended, its shallow attack upon the recent teachings of sanitary science.

CITY FILTH—THE WAR OF CLOSETS.

The poet's aspiration, that we might be given the gift of seeing ourselves as other people see us, is certainly superfluous in these days of a freely flowing press. The other people have not the least hesitation, and do not want the full opportunity of themselves stating what they think of us. M. le Dr. Van Overbeek de Meiges, professor of hygiene in the University of Utrecht, has favoured us with a very frank disclosure of his opinions regarding our position on sewage matters in this country, not very gratifying to our self-esteem, however useful it may be for our instruction ("Les Systèmes d'Evacuation des Eaux." Baillière et Fils, 1880). Dr. de Meiges, condemning us from the mouths of our own engineers and sanitary workers, depicts with an unsparing hand the shortcomings of our watercloset system and system of sewers, as compared with the advantages attaching to the dry-closet systems—such a system, for example, as is now being carried into force in Manchester; and he shows how what we now suffer from has not been peculiar to us, but has been experienced by all places where the "English system" of sewerage has been put in force. He maintains that our system is noxious whether used with or without irrigation, and that it is necessary that all fæcal matters should be kept out of our sewers, if we would escape mischief. It is war to the knife between him and the followers of Rawlinson. His argument has the faults of all one-sided views, but he brings together a very large quantity of material bearing upon the subject he discusses, and hence his work is very instructive and of great interest. He does not bring anything forward that is new to us of the defects of the "English system," but he omits to say much of the advantages which have been claimed. Those defects have prompted the experimental trials of the mixed systems of sewage disposal now in progress at Manchester and Rochdale and elsewhere in England. Those trials are a protest against the "English system," as Dr. de Meiges understands it, and are of a sort he would approve. We are content to wait the results of these trials before we accept so unqualified a condemnation of the water-system as he utters, and believe it will be found that both the dry and wet systems of filth-disposal have their proper place in sanitary administration.

The Rev. Septimus Hansard, the Rector of Bethnal-green, has set an example of citizenship in sanitary work which may be usefully followed. When first he entered upon his rectorship he was informed that neither flowers nor grass would grow on the rectory lawn, so inimical was the local atmosphere to vegetable life. Whereupon he resolved to better the atmosphere by ridding it of some of its smoke and foreign admixtures from neighbouring manufactories. He set himself to take notice of smoky chimneys, and by reporting them to the police, and taking advantage of the law of nuisance anent smoke, he contrived to ameliorate local states of atmosphere, so much that he is now reported to cultivate the choicest flowers readily.

A very foolish statement has been made at Chertsey with reference to a case of small-pox which has recently ended fatally in the Chertsey Union. It is implied that the nature of the disease was first mistaken by the medical practitioner called in at the beginning, and that the patient was improperly treated in the union workhouse. The terms in which the statement found its way into the local press prove that it emanates (thoughtlessly no doubt) from a source wholly unconscious of the foolishness contained in it. But how comes it that Chertsey has not an infectious disease hospital apart from the workhouse?

From Canada the news comes of the prevalence of typhoid fever in Montreal, the Health Office reporting 130 cases, the majority of which have been traced to defective drainage. Also a serious outbreak of diphtheria has occurred in the neighbourhood of Sandwich.

THE SERVICES.

WAR OFFICE.—2nd Life Guards: Surgeon Percy G. R. Young, from the Army Medical Department, to be Surgeon, *vice* H. P. Hensman, promoted into the 1st Life Guards.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major C. G. Irwin, M.B., to be Brigade-Surgeon, *vice* W. C. Roe, granted retired pay; Surgeon-Major R. O. Hayden, from half-pay, to be Surgeon-Major.

Surgeon Albert Baird Seaman has been notified that he is to receive a medal and a gratuity of £100 in consideration of his services in the Khyber Pass.

Deputy Surgeon-General J. O'Nial, Army Medical Department, late Principal Medical Officer of the Candahar Force, has arrived in England, and has been appointed to the Administrative Charge of the North British District, Edinburgh.

In compliance with instructions received at Aldershot from the Adjutant-General, Horse Guards, the undermentioned officers of the Army Medical Department have proceeded from the Camp to Dublin for temporary duty in Ireland—viz., Surgeons-Major A. Macrobin and F. Waghorn, and Surgeon B. Connolly. These officers, on arrival at Dublin, have been directed to report themselves to the general officer commanding the troops and the principal medical officer. In consequence of the departure from Aldershot of the above-named officers, the following medical arrangements have been made at the Camp—viz., Surgeon-Major Leask to take medical charge of the troops of the Royal Engineers, Army Hospital Corps, and Army Service Corps, *vice* Surgeon-Major Waghorn; Surgeon-Major T. Hession to take medical charge of officers, women, and children, South Camp, *vice* Surgeon Connolly; and Surgeon Crofts to take medical charge of the troops of the 1st Infantry Brigade, *vice* Surgeon-Major Macrobin.

THE TRANSVAAL WAR.

A strong reinforcement of medical officers has been warned for service at the Cape, and the following are under orders to embark at Portsmouth with the troops in the transports *Queen*, *Hankow*, and *Ararat*. Brigade-Surgeon Sampson Roch, Surgeon-Majors David Leslie, W. P. Smith, J. Leask, Scanlan, Heather, Malley, A. Thompson, L. H. Giraud, with Surgeons Cross, Drury, Brown and Powell. A detachment of the Army Hospital Corps, numbering sixty-three non-commissioned officers and men with two officers, Lieutenants of Orderlies, Philips and Strange, will also proceed in one of these transports. The men will be completely equipped and will be armed with revolvers. Six ambulance waggons, sixty medical comfort boxes, containing brandy, port wine, essence of beef, arrowroot, preserved milk, mustard, &c., and lightly packed as to be readily carried on a mule or ox, have been forwarded by mail steamer to Durban, the port of disembarkation. The transports will take out additional quantities of chloroform, medicines, medical and surgical instruments, and material, field panniers, field companions, medical comforts, and disinfectants, for the use of the troops of the expedition.

BOMBAY MEDICAL RETIRING FUND.—It is announced from the India Office that the following is the allotment of annuities for 1881:—£252 to Surgeon-General J. R. Miller, M.D.; £210 to Surgeon-Major F. W. Harris; £210 to Deputy Surgeon-General R. G. Lord, M.D.; £168 to Surgeon-General W. G. Hunter, M.D.; £168 to Deputy Surgeon-General F. G. Joynt, M.D.; £168 to Surgeon-Major W. E. Wood.

ADMIRALTY.—Surgeon W. H. Colahan, M.D., has been promoted to the rank of Staff Surgeon in Her Majesty's Fleet, with seniority of Dec. 28th, 1880. The following appointments have been made:—Staff Surgeon Septimus Sexton to the *Iron Duke*, additional, for service in the *Magpie* when recommissioned; Surgeon J. A. M'Munn, M.B., to the *Iron Duke*, additional, for disposal; Surgeon James B. Armstrong, to the *Fly*, when recommissioned; Surgeon William J. B. Bookey, to the *Foxhound*, when recommissioned; and Surgeon James B. Clibborn, to the *Vigilant*, when recommissioned.

PHARMACOLOGY AND THERAPEUTICS.

TANNIN.

Lewin has found that tannin ceases to coagulate albumen and fibrin if it be treated with an alkali until the mixture has a slightly alkaline reaction. This alkaline tannate is readily decomposed, but it cannot be obtained in a crystalline form. Although the compound does not coagulate albumen, it produces in the mouth the characteristic astringent sensation. Tannin will precipitate pepsin, and coagulate peptones, and hence it has been supposed to interfere with the process of digestion. But, according to Lewin, this conclusion is erroneous, for such precipitated peptone is readily soluble in a little hydrochloric acid, and the presence of this acid is sufficient to prevent such coagulation from taking place. In some experiments in artificial digestion, he found that the presence of tannin did not in the least interfere with the digestion of albumen and fibrin by pepsin and hydrochloric acid; peptones were formed just as if the tannin had not been present. A solution of tannin being added, drop by drop, to blood or lymph, a permanent coagulation of the albumen did not take place until the alkalinity of the blood was neutralised. This is explained by the fact that the tannate of albumen is soluble in alkaline carbonate, and is not precipitated as long as the alkaline carbonate is present. The antiseptic action of tannin was long doubted because fungi grow in its solution. This is, however, the case with many other agents which retard decomposition; and the antiseptic influence of tannin has been proved by experiments, which are confirmed by Lewin. It not only prevents decomposition of organic substances, but will arrest the growth of the yeast-plant. An investigation into the action of tannin on living muscles seems to demonstrate that the muscle becomes less extensible, but considerably more elastic, so that, when the extension is over, the muscle regains its original length more nearly than in health. It is a similar condition to that which is met with during rigor mortis. Temporary arrest of the supply of oxygen has a similar effect on a muscle. Lewin conjectures, therefore, that the tannin produces its effect by transforming the alkali of the blood and lymph into the soluble tannin compound, which tends to abstract oxygen from the tissues, and to produce the local manifestations of anoxæmia. It is this influence, he suggests, that determines the contraction of vessels under its influence, and has led to its general employment as a styptic. He has found that after the injection of a solution of tannin beneath the skin of a frog's leg the muscles become pale and firm, just as if frozen, and their larger vessels are almost empty, although the chief arteries of the limb are well filled.

INHALATIONS OF NITROGEN IN LUNG DISEASE.

Inhalations of nitrogen have been employed by Kohlschütter as a means of hastening absorption within the lungs, according to the suggestions of Steinbruck and Treutler. Air containing 90 per cent. of nitrogen was inhaled daily for half an hour, and an increase up to 96 per cent. was borne without inconvenience. Under this treatment defective resonance due to chronic infiltration of the parenchyma of the lung or old pleuritic exudations quickly disappeared. In many cases the amount of cough and expectoration was increased, in consequence, it is supposed, of liquefaction of the exudations. There was usually a distinct elevation of temperature, sometimes reaching 104° F., and accompanied with other evidence of pyrexia. In some of the cases the temperature began to rise soon after each inhalation, but gradually became less after successive inhalations, a tolerance being established. In other cases there was a continuous elevation of temperature, of moderate degree, which only ceased on the discontinuance of the inhalations, and in some patients, in spite of the cessation of the treatment, passed on into the hectic of the phthisical, accompanied by signs of rapid breaking down of the lung, the formation of cavities, and the progress of the disease. Besides this effect, somnolence was observed during the treatment, and an inclination to sweat, especially at night, apparently in connexion with the pyrexia. Kohlschütter explains these effects as the result, first, of the deep inhalations taken by the patients during the treatment, and, secondly, by the changed composition of the air in the lungs assisting in the destruction of the elements of exudation. He recommends further experiments in lung disease, but only in cases in which there is no breaking down of the lung tissue or hectic fever, and points out that the method of treatment requires careful watching, since it is clearly powerful for evil as well as for good.

POISONING BY CARBONATE OF BARYTA.

A girl, twenty-eight years of age, pregnant, died under the care of Professor Seidel at Jena with symptoms indicating the action of an irritant poison—repeated attacks of vomiting, abdominal pain, diarrhœa, and collapse, with, towards the last, difficulty in swallowing and breathing. Death occurred about thirty-six hours after the onset of the symptoms. After death the stomach was found to contain a moderate quantity of reddish-brown liquid, and in both stomach and duodenum there were submucous ecchymoses, and on the mucous membrane were numerous minute hard white grains. The liver presented fatty degeneration; the other organs were normal. Arsenical poisoning was first suspected, but a packet of white powder, labeled "poison," was discovered, and recognised by a chemist as containing carbonate of baryta, sold by him for the destruction of rats. The statement was verified by chemical analysis, which also showed the identity of the powder with the white grains found in the stomach. Poisoning with the salts of barium is very rare, and M. Seidel has found only eight cases recorded in medical literature. All the salts of barium are poisonous, with the exception of the sulphate and fluo-silicate. The carbonate has been regarded as innocuous, but is no doubt converted in the stomach into the poisonous chloride, and, as this case shows, is as toxic as the other salts. The similarity of the symptoms with those of poisoning by arsenic is a point of considerable interest.

BELLADONNA POISONING TREATED WITH CHLORAL.

Atropin has been successfully employed to antagonise the effects of chloral in poisoning by the latter drug. This fact suggested to Dr. Trocquart, of Bordeaux, that chloral might be equally useful in poisoning by belladonna. A chemist was troubled with tinnitus aurium, and was advised to try belladonna for its relief. He took a handful of leaves, and infused them in a small quantity of boiling water, and drank the infusion. Half an hour later he was seized with gastric pain, excitement, and giddiness. Tartar emetic was administered, which caused some vomiting. Three hours later he was wildly delirious, shrieking out, and was restrained with difficulty by four persons. His face was flushed, covered with sweat, and his pupils were widely dilated. Each attack of delirium lasted for four or five minutes, and between the attacks were intervals of utter prostration. A dose of chloral was ordered, but could not be given on account of the patient's violence. A few hours later, however, five grammes of chloral were administered in an injection. The violent paroxysms quickly subsided. Whenever there was any indication of a return another dose of chloral was administered. The patient passed a quiet night, and woke up next morning with merely considerable muscular fatigue.

THE ANTAGONISMS OF ACONITIA.

An important series of investigations by Dr. Ringer and his assistants into the action and antagonistic actions of aconitia, atropia, and pilocarpin on the frog's heart have led to the following conclusions. Aconitia slows and weakens the heart and incoördinates the ventricular contraction. The incoördination precedes the weakening, and sometimes the contractions, though slow and incoördinate, continue strong until the heart stops. The effect on the ventricles is far more rapid and powerful than on the auricles, and the whole effect on the heart is less powerful than that on the cerebro-spinal centres, for after complete paralysis the heart often continues to beat well for a considerable time, and the general depression which follows a poisonous dose of aconitia is chiefly due to its action on the central nervous system. Atropia antagonises the action of aconitia on the heart, it restores contractions in a heart which has been arrested by aconitia, and strengthens, accelerates, and coördinates the heart simply weakened, slowed, and incoördinated by aconitia. There is no antagonism between aconitia and muscarin, or pilocarpin. Atropia, however, antagonises the combined effects of aconitia and muscarin, and of aconitia and pilocarpin. Dr. Ringer agrees with the opinion that antagonisms are due to chemical displacement, and believes that atropia antagonises muscarin, pilocarpin, and aconitia because it has a stronger affinity for the muscular and nervous structures of the heart than these substances, and displaces them, replacing their effect by its own.

THE ACTION OF SQUILLS ON THE HEART.

The action of squills upon the heart has been found by Röhmann to resemble that of digitalis. After the injection of a fresh watery infusion, or of an extract, into a vein of a curarised dog, the pulse was retarded, and the blood-pressure rose. Afterwards, the pulse increased in frequency, while the blood-pressure remained high, or fell. When the stage of accelerated pulse and of lowered blood-pressure had set in, a fresh injection again slowed the pulse, without any corresponding elevation of the blood-pressure. These effects occurred after division of the vagi, but if the vagi were divided after the retardation of the pulse, and the blood-pressure had risen, no further action could be obtained by further injections. Röhmann assumes that the increase in the blood-pressure is the result of an irritation of the vaso-motor centre, while the changes in the pulse rate are due to an initial stimulation, and subsequent paralysis of the centre of the vagus, the intra-cardiac terminations of this nerve remaining for a time excitable. The pulse tracing, however, compared with that of digitalis, shows much broader and flatter curves. It is probable also that squills has an action on the muscular tissue of the heart, similar to that of digitalis. These experiments show that there may be some ground for the objection, which practitioners have occasionally expressed, against the use of squills in the acute bronchitis of children.

BENZOIC ACID.

Schulte has found that the introduction of benzoic acid into the stomach of warm- and cold-blooded animals always causes irritation of the mucous membrane, extravasation, and hæmorrhagic erosion, and that similar irritation is sometimes observed even when benzoic acid or its salts have been introduced by injection under the skin, or into a vein. In the latter case the pulse and respiration are at first accelerated, and afterwards retarded. The blood-pressure is not influenced by slight injections, but is lowered by stronger ones, and the phenomena are independent of the vagus nerve. Whenever the dose amounts to more than two-thousandths of the body weight of the animal, toxic symptoms occur, followed by death. Salkowski has pointed out that when benzoic acid is given the urine commonly contains a substance which is capable of reducing sugar. This body is not soluble in ether, but it is soluble in alcoholised ether and acetic ether. It is very slightly soluble in water, and thus is distinguished from both benzoic acid and hippuric acid. The salt it forms with barium is insoluble in water, and contains both nitrogen and chlorine. Schulte has found that the appearance of this substance in the urine corresponds in time with the appearance of toxic symptoms. In the therapeutic use of benzoic acid and benzoate of soda for diphtheria, acute and subacute articular rheumatism, erysipelas, typhus, diabetes, nephritis, interstitial phthisis, peritonitis, &c., the reducing substance was never found in the urine after a small subcutaneous injection, but was found when a larger injection was given. The salt was found distinctly useful only in acute articular rheumatism and diphtheria.

THE LOAN EXHIBITION AT THE ROYAL ACADEMY.

AT Burlington House there is just now a collection of works by the Old Masters and by the deceased masters of the British school, as well as a collection of drawings by John Flaxman, R.A., a large proportion of which is contributed by University College. Although this is the twelfth year in which the council have applied to the owners of the art treasures of England for the loan of their works, so far from the present exhibition betraying any signs that the sources of supply are being exhausted, one cannot help feeling, on the contrary, that there has never been brought together such a splendid collection as that which the public has now the privilege of examining. The drawings of Flaxman are especially interesting. Some day the English will awake to the knowledge of the extraordinary power of this artist. At the present time he is more valued abroad than at home. Amongst the paintings are works by Raphael, Rembrandt, Teniers, Van Dyck, Velasquez, Paolo Veronese, Wouverman, Paul Potter, Sir Joshua Reynolds, Wilkie, Lawrence, Gainsborough, and numerous others of like renown. The exhibition is especially remarkable for the fine specimens of George Morland, some of whose works, as here exhibited, will surprise those who have been accustomed to associate him almost exclusively with drawings of Hodge, with a pitch-fork at hand, looking over a wooden fence at a huge pig. The pleasure of a visit to this exhibition is not, however, without some alloy; for when the May exhibitions are brought to mind comparisons are suggested which cannot fail to make the thoughtful wonder whether the large prices commanded by the painter of to-day have a really beneficial effect upon the progress of art in this country.

THERAPEUTIC NOTES.

(*Communicated* by DAVID PAGE, M.D., M.R.C.P.)

IN the treatment of Tetanus and Trismus, Spoerer has successfully employed hot-water compresses. He dips a large enough piece of coarse flannel in water of a temperature which can just be borne by the hand (50° to 55° C.), and applies the compress to the occiput and along the spine.

Quebracho has been used by J. R. Berkart as an efficient palliative in the dyspnœa of emphysema, atheroma, and fatty degeneration of the heart. Relief followed within three minutes after the exhibition of a teaspoonful of the fluid extract.

In purulent inflammations of the urinary tract, French has found kava-kava an efficient remedy, and has also used it with success in four cases of cystitis. In urethritis the formula he employed was, sixty grammes of the fluid extract of eucalyptus globulus, twenty grammes of the fluid extract of kava-kava, two grammes of benzoic acid, and twelve grammes of powdered borax; three teaspoonfuls daily. According to the statements of Dupuy, kava-kava is a sialogogue, a bitter; to a slight extent a nervine stimulant, and a blennostatic. In acute urethritis and vaginitis, the resin obtained from kava-kava was likewise proved satisfactory in allaying pain and diminishing secretion.

MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—An experience of nearly eight years in private tutorial work, and of four years as medical tutor at the Westminster Hospital, is my justification for adding another to the numerous letters which have appeared in your columns on the subject of Medical Education.

Mr. Bruce Clarke has pointed out a great difficulty in the way of a sound medical education—namely, the imperfect manner in which the preliminary studies of aspirants to the profession has been carried on. An attempt to solve this difficulty has recently been made by the College of Physicians of London. Its scheme encourages students to master botany, materia medica, chemistry, and osteology before entering a hospital; so that those who have passed this examination prior to beginning their hospital career will not only have four clear years in which to study anatomy, physiology, surgery, medicine, midwifery, &c., but they will also have acquired a certain amount of scientific training, and the power of working independently, the want of which is a great drawback to youths entering fresh from school.

Unfortunately the recent examiners at the College of Physicians still keep in the old groove, as in the first paper under the new plan I see that the pharmacopœial process for obtaining morphia is asked. I cordially agree with Mr. Butlin in his suggestion, that the amount of ground to be traversed should be limited. Among the subjects to be excluded should be the preparation of the alkaloids, as I know from experience that this is purely a matter of cram, usually being left to two or three days before the examination. I am glad to see that only a slight acquaintance with botany is required by this scheme.

In conclusion, if I might be allowed to sum up, I would say that the reforms in medical education which seem to me to be the most imperative are, first, an improvement in the preliminary studies—i.e., that students should be compelled to pass in botany, chemistry, and materia medica before entering at a hospital. It would follow as a corollary that attendance at lectures on these subjects would not be required of a student after he had entered, thus affording an increased amount of time for more important work. Second, that Mr. Christopher Heath's suggestion of two years' interval between the passing of the first and second examination at the College of Surgeons should be strictly enforced.

I am, Sir, your obedient servant,
F. DE HAVILLAND HALL,
Assistant Physician to the Westminster Hospital.
e-street, Dec. 23rd, 1880.

To the Editor of THE LANCET.

SIR,—As the question of medical education is exciting much interest, of which the multitude of letters in your columns is evidence, I would venture to offer a few remarks on the subject, as one who has recently passed through the ordeal. You have heard the opinions of the teachers and examiners, the men attached to schools and colleges, that it is better to have a longer hospital course, and that this should be preceded by a good scientific examination. Each of them favours his own subject and wishes more attention was given to it; others, men of good general education, wish to see a preliminary examination in their speciality, more thorough and effective. The general practitioners are all for what they call the *practical* aspect of the question: a man should know how to dress this wound or that sore, and use such or such an instrument, besides having a practical personal acquaintance with pharmacy and dispensing, and as the one source effective in acquiring such working experience and knowledge, they advocate pupilage for the first two years to a general practitioner. There is reason in all these remedies, but the difficulty is to select a workable scheme, which will not be too long or too expensive, and which will yet give us a better educated class of men than the present general practitioners. The following seems to me to contain, at any rate, some of these requisites.

General education to continue to the age of seventeen, when the candidate can present himself for an examination, consisting of two parts, (*a*) general and (*b*) scientific, which may be passed simultaneously or at different times. This would be the preliminary examination, and satisfactory certificates in both parts a necessity for admission to the register before commencing study as medical students. The subjects of general education should be—1. English (much more than is usually demanded). 2. Latin, translations from one or two of the ordinary school authors, and grammar. 3. One modern language at least. 4. Mathematics, arithmetic, algebra, and Euclid. The science should comprise—1. Chemistry. 2. Natural philosophy. 3. Botany. 4. Zoology. Only an elementary knowledge of each would be required, and its range should be distinctly scheduled; but all should be supplemented by *vivâ voce* and practical work when possible. Additional subjects might be permitted or more advanced papers on the above.

After this preliminary examination, which would very much resemble the matriculation and preliminary scientific of London, or previous examination and 1st M.B. of Cambridge, combined and made easy enough to suit the general capacity of those who enter the profession, the student might register and immediately begin to study anatomy and physiology at some medical school. Now, I wish to make a protest against the advice so often given to the young student, "Go into the wards, and see all you can in the out-patients' department," from the first day he enters the hospital. It is undoubtedly the thing he ought *not* to do; let him devote his whole time and energy to his anatomy and physiology for the first year or eighteen months, only going into the out-patient rooms say twice a week for an hour each time, and round the wards for the same limited time on two or three other days. Why the examining bodies require certificates of attendance on courses of lectures I do not see. Why can they not be content to examine a man and by the results refer him back or allow him to proceed in his studies, without wanting evidence of how and when he gained his knowledge? By insisting on these certificates they hamper a student in the whole of his course, confuse him with a multiplicity of subjects, and regulate the time he is to spend over them, so as to make him waste it to the utmost. They should remember they see *only* examining bodies. The General Medical Council should regulate the studies as to amount and order in the examinations.

We have seen that a student of diligence and well-directed study might thus pass his examination in anatomy and physiology in one year, or a year and a half at most. To attain this end the examining bodies must consent to diminish the present time required in the dissecting room by a year. We have now three years, or two and a half, left to devote entirely to the study of medicine, surgery, midwifery, &c., and it is in this way that I would propose to provide some, at any rate, of the extra time for study demanded by Mr. Savory:—The final examination should consist of two parts—(*a*) medicine, including pharmacy and therapeutics, hygiene, medical jurisprudence, and midwifery; and (*b*) surgery, including ophthalmic, aural, and other branches. The subject of pharmacy and therapeutics is usually lectured to students in their first year; but this, I maintain, is decidedly a waste of time: the application of, and examination in, these subjects is at the end of the course, and so ought the teaching to be. The student might be allowed to present himself for the medical and surgical divisions of the examination at the same or at different times.

Now, here is the proper time and place for the apprenticeship of pupilage which general practitioners insist so much on, or for making use of the vast field, at present uncultivated, which our provincial hospitals, unions, and such places present. No one can deny the advantage, or absolute necessity, for one in our profession to have had the semi-responsible charge of patients, such as our hospital house-physicians and surgeons have, if he is to be successful in assuming the entire care of them in private practice. The London University has recognised this fully, and requires all candidates for its degree to produce evidence of having held such a position for six months; and there is no reason why the same wise regulation should not extend to every member of our profession before he receives permission to practise on his own account. The student, after passing his examinations in surgery and medicine, might receive certificates to that effect, and be obliged to then hold an appointment for six months as house-physician or house-surgeon to some public institution, or as qualified assistant to some general practitioner before he is handed his diplomas and allowed to register. The general practitioner should have a large practice, including clubs, unions, or mines, or other appointments affording an extensive field for gaining experience. The student being qualified might justly get his board and lodging, and perhaps some emolument; and while thus gaining valuable and necessary experience, his course of study would be lengthened, to the satisfaction of Mr. Savory, I hope, without any or little additional expense. Whether the provincial hospitals and other institutions would help in such an arrangement, I do not know; but Dr. Strange, in your issue of the 18th December, does not seem to apprehend any difficulty from them. Such a curriculum would, I think, satisfy the several demands of students, teachers, and general practitioners for reform in our present system. It may be much improved by others, but it is the best I have been able to elaborate after much thought; and as a suggestion I offer it to the consideration of the profession now, when the subject of remodelling medical education is so prominently brought forward.

Apologising for the length of this communication,
I am, Sir, yours, &c.,
H. HOWARD MURPHY, M.D. Cantab.
Twickenham, Jan. 1881.

To the Editor of THE LANCET.

SIR,—Having read with great interest your own valuable comments upon this subject, and also the wise and important suggestions of Mr. Savory, Mr. Heath, Dr. Strange, and others, and having had many years' experience amongst students as a collegiate lecturer and private tutor, may I, as the result of all of it, make the single suggestion, that the addition of one single year to the period of study, making five years instead of four years, would remove every difficulty with all the reasonably industrious students, and enable them to comply, moreover, with necessary requirements, and secure the acknowledged benefits suggested by one or other of your correspondents? What are the objects which should and must be obtained? These are in the main three.

1. *More adequate time for the student's work.*—This would be secured, for the extra year would double the period for some of his subjects, and enable him to do his work well, instead of too often most indifferently, for want of time.

2. *A division of subjects and examinations.*—This could be more efficiently secured, both being most desirable, and a first examination in all his scientific subjects should include his anatomical and physiological, at the end of the third year at latest. His two winters' anatomy, without which no student can learn the subject, would also be easily secured. It would also enable him to devote at least two full years afterwards exclusively to hospital work and practical subjects.

3. *Some time spent with a practitioner.*—This object would be most easily secured by residence being made compulsory with a practitioner during his first two years, a practice easily complied with and most beneficial. The only real objection to the seven years of Mr. Savory, I think, is the considerable extra outlay which would be required by the student. Would it not be well to try a less onerous addition to the period, which would, I believe, suffice and act admirably? I have very long felt that all the subjects which it is desirable for a student to study at a college or school should be examined upon; for too often, without this, mere attendance in classes for the purpose of completing schedules only leads to a complete waste of time in a good many cases. The examination might be lighter or more difficult, in accord with the aim of the student, and also in proportion to the direct value of the subject to medicine.

I am, &c.,
WILLIAM HINDS, M.D., &c.

Easy-row, Birmingham, Dec. 19th, 1880.

RETARDED SIGNS IN PNEUMONIA.

To the Editor of THE LANCET.

SIR,—When writing my paper on Retarded Signs in Pneumonia, it was not my wish or intention to lay claim to making any fresh or original observations upon the physical signs of that disease, but simply to call attention to the greater frequency of late discoverable signs. The following paragraphs, which are extracted from my paper, I think, will show this:—"I believe that physical signs, such as dulness on percussion, bronchial breathing, and bronchophony, occur later in the course of the disease than is usually supposed, or perhaps it would be more correct to say, that there is a larger percentage of cases with lately discoverable signs than our reading or teaching has hitherto led us to think." Again, "If this dulness, bronchial breathing, and bronchophony are frequently lately noticed—*for all authors admit these signs are occasionally either overlooked or lately discovered*—then it becomes necessary to diagnose the disease by symptoms instead of by signs."

I have read several articles on pneumonia, and also Dr. Sturges's book upon the clinical history of that disease, and failed to find that prominence given to the above cases which they appear to deserve. The question whether these late signs are really due to the disease having commenced in a central situation in all cases, I think, is doubtful, but as far as my own go, I believe the central origin of the disease fully explains them, for the crisis generally appeared a day or so after the signs were discovered.

In my last case, that of a girl aged seven years, the dulness was detected on the fifth and the crisis followed on the sixth day of the disease.

In the cases mentioned by Dr. Sturges in his letter to you, in which the physical signs commenced about the sixth day, the crisis not occurring for six or seven days later, might not these be the cases which have a constitutional origin, as suggested by Dr. Yeo and Dr. Goodhart during the discussion of the paper?

I am, Sir, yours obediently,
W. JOSEPH TYSON.

Folkestone, Jan. 3rd 1881.

"LISTERIAN" OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—As the discussion at the Medico-Chirurgical Society, last Tuesday, shows pretty strongly that there is a considerable difference of opinion as to the relative merits of antiseptic or non-antiseptic ovariotomy, I may be permitted to record my own most recent experience of the operation. I have had fifty operations during a period of about two and a half years, and in these I do not include other cases of abdominal section, such as simple exploratory incision, removal of myoma, or incomplete cases, nephrotomy for pyosalpinx, &c., of which there were twenty-nine in the same period. I hope in due course to be enabled to publish a complete list of all such from the commencement of my practice.

Of the 50 ovariotomies only 1 patient died. This series includes 34 for ovarian tumour (ovariotomy proper) and 16 for oöphorectomy. The results were 21 successive recoveries; then 1 death; then 28 successive recoveries. The death occurred in the case of removal of a parovarian cyst, forty-four hours after operation; it was very sudden, with symptoms of coma. The cases were taken without selection, and were of the average difficulty and danger. Two of them were, I consider, much above the average in this respect—e.g., the case of J. B——, aged thirty-nine, a large left multilocular cyst, easily removed. Twelve hours afterwards, when I was sent for, I found her in extreme collapse; the abdomen was reopened under spray, and the ligature was found to have slipped, the pedicle was tied again, and quite two pints of clotted and fluid blood were scooped out of the abdomen and pelvis. After a most tedious "toilette du péritoine," the wound was again closed, and the patient did well. In the second case, E. R——, aged thirty-nine, a tedious and difficult operation, I placed a drainage-tube, as the tumour had been so adherent as to require partial enucleation. Six hours after the operation the sister at the hospital telephoned to me that they missed a pair of torsion forceps. On seeing the patient at once, I found her fairly well, though in pain, and I recommended a further search. Next morning, exactly twenty-four hours after the operation, she was in intense pain, anxious, quick pulse, though the temperature was not much raised; but as the forceps could not be found, I concluded they were in the patient's abdomen, and, under the spray, I cut the uppermost stitch, and made from it a fresh opening into the abdomen, above the umbilicus. After a short search I found the forceps, with lymph upon them, lying down against the left side of the spine. I made the fresh opening so as not to interfere with the drainage-tube or to allow its contents to enter the abdomen. The patient made a perfect recovery.

I believe all the operations were performed strictly antiseptically. The spray solution, in most cases, was 1 in 20—occasionally 1 in 30—making the spray itself about 1 in 40, or 1 in 60. The wounds were dressed, in about the first half of the number, with gauze, and since then with the carbolised absorbent cotton-wool introduced by Mr. Gamgee. I have never pretended to conduct the treatment, after operation, strictly antiseptically; for I have looked upon it as of the very first importance to conduct the operation itself with the strictest antiseptic care until the peritoneal wound has closed, which is well known to take place very quickly; and, after that, that the abdominal wound may be treated on ordinary principles as an incised wound, which plan will not influence the result, and is a matter of a very short period, more or less, in the ultimate recovery of the patient. Of course, many of the cases healed without any pus; but I have been convinced that others have not healed quite as quickly as those of Mr. Tait, who has not regarded antiseptic principles as of the same importance as myself. Of this I have never been anxious, so long as I was satisfied that the peritoneal cavity had been exposed to only a carbolised atmosphere; for it is so well known how easily this cavity is shut off when the edges of the wound are brought together, even before the sutures are tied, making it sometimes no easy matter to insert one's finger, as, for instance, to extract the flat sponge.

I have usually ascribed the more tardy healing of the wound, when such did occur, to the action of the dressing, rather than of the spray, as my carbolised wool was made without measuring the acid, and was known to be more strongly impregnated at one time than another.

In none of the cases was there an excessively high temperature, or a frequent pulse observed, which could possibly be considered as due to carbolic poisoning.

In eighteen cases the clamp was used, and in thirty-two the ligature; in one of the latter a drainage-tube was also inserted. In the patient who died the pedicle was tied. One patient was in the fourth month of pregnancy, and was afterwards confined at term of a living daughter.

I am, Sir, yours truly,
Birmingham, Dec. 18th, 1880. THOMAS SAVAGE.

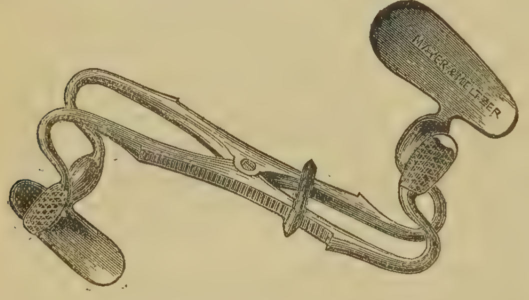
P.S.—Since writing the above, the patient upon whom I last operated died four days ago, so that my statistics should be stated as 2 deaths in 50 operations, and not 1 in 50, as stated above. The death was due to one of those unforeseen and, as far as can be told at present, unpreventable causes—viz., tetanus, which will always be liable to step in and raise the mortality of ovariotomy, apart from the question of antiseptics or non-antiseptics. The patient was perfectly well up to the ninth day; wound healed without pus; sutures removed, and looking forward to leaving the hospital. She first complained of a little "cold" from a window draught, and from that symptoms of tetanus developed, which terminated her life in twenty-four hours. At the post-mortem made by Dr. Saundby there was no appreciable cause for death. The abdomen was quite healthy; a piece of small intestine was adherent to the stump, and there was not a trace of serum or pus to be seen in the pelvis. I am now sorry that I did not wait a little longer before sending the record of my last fifty cases; but I was anxious to make the contribution as soon as possible after the Medico-Chirurgical Society's discussion.

December 27th, 1880.

NEW FORM OF GAG.

To the Editor of THE LANCET.

SIR,—I would venture to recommend a somewhat novel form of gag, which will be found useful in operations for the removal of tonsils, and in some cases of staphyloraphy. The instrument is essentially Mr. Rose's double-ended modification of Mr. Coleman's gag, to which Messrs. Mayer and Meltzer have adapted an ingenious sliding-ring-catch, to keep it open. To this a tongue-plate is now added, so that the gag answers almost all the purposes of the more expensive instrument usually employed in operations on the palate. The accompanying illustration will probably save the necessity of a further description.



I am, Sir, yours obediently,
Stratford-place, Dec. 31st, 1880. THOMAS SMITH.

ON CHIAN TURPENTINE AND PROF. CLAY.

To the Editor of THE LANCET.

SIR,—I deeply regret that the remarks with which I prefaced the report of my cases, and which were intended to convince Prof. Clay of the readiness with which we gave the Chian turpentine a fair trial at the Middlesex Hospital, and the satisfaction with which we should have welcomed any measure of success from it, have failed in their object, and have apparently left room for him to suppose we have "a prejudice against the Chian turpentine treatment not justified by the cases recorded." I would also mention for his information that the resolution of the Medical Committee was passed not owing to the results of my experience alone, but to those of my colleagues as well.

Although Prof. Clay says in his letter of last week, "I have never yet affirmed Chian turpentine to be a positive cure for cancer," I think it very pardonable if he has been misunderstood on this point; for he has made statements which to the ordinary mind distinctly imply the contrary. For instance, in his first communication (THE LANCET, March 27th, 1880) he has written, "Judging by my experience it is no figurative expression to say that it acts as a direct poison upon the growth, probably causing its ultimate death...... In the early stages of cancer it may be affirmed that *an undoubted cure may take place speedily,*......and experience justifies the expectation that under such circumstances a recurrence of the disease will not follow." He has recorded a case (Case 2) in which the os and cervix uteri "were enlarged from carcinoma to the size of a hen's egg. The os was dilated and the cavity of the cervix was filled with epithelial growth which bled freely"; and the result of treatment is described thus: "The case was a most remarkable one. The turpentine acted upon the growth with great vigour, literally melting it away in the brief period of four or five weeks," and it is added, "*She had continued quite well.*" In his second article (THE LANCET, October 2nd, 1880) Professor Clay says, that the cases previously reported by him "are unique of their kind, for, as far as I know, they are the only instances on record of cancer being *cured* solely by the administration of an internal remedy. I feel justified, therefore, in stating that uterine cancer at least may be removed by the use of Chian turpentine." And further on he writes: "It is possible, therefore, to formulate a line of treatment which shall be successful in cancers of the uterus." In short, his writings teem with phrases which imply, when they do not absolutely state, the curative agency of the treatment he advocates.

Nor do his published statements permit him to object, consistently, to my cases on the ground of their severity, and to say, "It was never contemplated by me that the remedy should be used in the treatment of cases verging on death, as five of the uterine cases reported by Mr. Morris evidently were." On referring to Prof. Clay's first case we find him stating, "The patient evidently had *not a long time to live.* The uterus was so extensively destroyed by the cancerous ulceration that its cavity readily admitted three fingers." The case was so desperate that it seemed to Prof. Clay justifiable to try the Chian turpentine "even if the remedy should produce unfavourable symptoms." Yet on the twelfth day, as he informs us, "the os was quite contracted and would now scarcely admit the finger;" in the twelfth week the parts were cicatrising, the patient's health good, and she could walk a mile or two easily. In his second paper Prof. Clay says: "It is advisable not to be too precipitate in rejecting a case of uterine cancer on the ground of its being too far advanced for treatment," and he then goes on to state how that the patient, who is said to have been told at the Middlesex Hospital "that her case was incurable, and that *she had not long to live,*" was so much improved in nine weeks that she was about to return to London, "with every prospect of soon being cured." In the face of these statements, it is perfectly amazing that Prof. Clay should object to any case short of one actually moribund.

But it is a distinct, although I am willing to think an unintentional, misrepresentation of my cases for Professor Clay to say respecting them: "Nor did I ever suggest or imagine that Chian turpentine would build up a new uterus, or repair a cancerous fistula of the intestines, or patch up a great cavity into the bladder, or restore a large recto-vaginal fistula with the fundus of the uterus extensively destroyed. Yet several of the cases described by Mr. Morris were of this character." These were the conditions brought about by the ravages of the disease during the administration of Chian turpentine over periods varying in the several cases from seven weeks to nearly seven months, and found at the post-mortem examinations; *not* the conditions at the time the treatment was commenced. Moreover, some of the patients who have been taking the medicine for months are still going about, although getting gradually worse.

Indeed, no one who will take the trouble to read my cases, as well as Professor Clay's, can arrive at any other conclusion than that even in the worst of my cases the cancer was in a less advanced stage when the turpentine was commenced than in those cases of Professor Clay in which h obtained such brilliant and merciful results.

If, Sir, it were not for the encroachment on your space, I would place brief abstracts of Professor Clay's cases, and a corresponding number of the most severe of my own, side by side, for immediate comparison; and it is with reluctance that I forego doing so.

I will, however, conclude by saying that if the twelve cases which I have published are not thought by the profession (for I fear I cannot hope to satisfy Professor Clay) to be sufficient, or sufficiently conclusive to show the utter uselessness of Chian turpentine in the treatment of cancer, I am prepared with other facts and cases in support of my opinion that "there is not a single symptom over which the drug seems to exercise even frequently, not to say constantly, an influence."

I remain, Sir, your obedient servant,

Mansfield-street, Dec. 13th, 1880. HENRY MORRIS.

SCOTLAND.

(*From our own Correspondents.*)

EDINBURGH.

THE past year has been rendered eventful in the Edinburgh Medical School by the managers of the Royal Infirmary suddenly abolishing the tutorial class of gynæcological instruction attached to the University wards. It is stated that the managers have under consideration the whole subject of tutorial classes, more especially those conducted by gentlemen who are not on the acting staff of the institution. The summary measure already adopted seems unsatisfactory to the mass of the teachers, and is decidedly unpopular with the students, who are well aware of the importance of such practical work, and who highly appreciate the benefits there obtained. In his inaugural address at the beginning of the session the President of the Royal Medical Society drew attention to the value of practical classes and ward work, and pointed out that all would gain by an extension and improvement in the tutorial system. One of the surgeons has been giving ether a trial since the beginning of the session; an inhaler and anhydrous ether are used just as employed by Dr. Thomas Keith.

On New Year's night the usual melancholy results of this "much too festive season" were apparent in the continuous stream of accidents that kept pouring into the hospital waiting-room. Among these were a compound fracture of the patella, a railway smash of the arm, necessitating amputation of the arm at the shoulder-joint, besides many simple fractures and cut heads. Most of this was due, more or less, to drink. A few cases of alcohol poisoning are reported from Glasgow.

At the annual meeting of the Scottish Society for the Prevention of Cruelty to Animals, held on Dec. 28th in Edinburgh, the Secretary stated that the cases reported by the officers of the Society had somewhat increased, the number for the past year being 311. The Chairman, Mr. Josiah Livingston, referring to the practice of vivisection, said they could do nothing to prevent this system of cruelty. Physicians and surgeons were licensed for the purpose of giving demonstrations, and they had no means of bringing those persons under the operation of the law. Another gentleman stated his belief that vivisection was certainly the most horrid species of cruelty to animals that could possibly exist. Councillor Sloan referred to several important discoveries in science and medicine made through the practice of vivisection, and said that the saving of a single man's life was worth more than all the cats and dogs in the town. Several ladies and gentlemen rose to their feet, and denounced Mr. Sloan's sentiments in an excited manner. When quiet had been restored, Mr. Sloan asked what a single human life was in comparison with all the cats and dogs nursed and pampered in the New Town? He was not there as an apologist for vivisection? But were researches in science and medicine to be baulked by mere sentiment? On its being stated that the question of vivisection was not before the meeting, the subject afterwards dropped.

GLASGOW.

THE medical schools of Glasgow were never in a more flourishing condition than at present. The total number of students attending the University this year is 2281, against 2220 last year, an increase of 3 per cent. In Medicine alone 557 students have entered, against 539 last year; so that, judged merely by numbers, the University has maintained and improved its position. The schools at Anderson's College and at the Royal Infirmary appear to share this prosperity. A feeling has lately been growing up, however, that it would be to the interest of both these institutions that their rivalry should cease and that their medical schools should be amalgamated; and the arguments in favour of this view are strong. This proposal has not yet taken any definite shape, and it is questionable if it can be satisfactorily carried out, considering that many of those more immediately interested would be sure to give it their hearty opposition. A fourth medical school has recently been started in Glasgow, in rooms situated at the gate of the University. Its lecturing staff consists of Dr. W. L. Reid, Mr. D. A. Knox, and Mr. D. C. M'Vail, who give instruction in obstetrics, surgery, and medicine respectively. It is still "the day of small things" with this school, but who knows what it may grow to?

Much interest is being shown in Glasgow in the movement for the erection of a hospital on the south side of the river. This scheme was, very properly, first taken up by the Glasgow Southern Medical Society two years ago, and from the amount of support which was at that time promised to it it is tolerably certain that it would long ago have been brought to a successful issue but for the unparalleled depression of trade which existed at that time, and which, perhaps, affected Glasgow more deeply than any other city in the kingdom. A few months ago the Hospital Committee of the above-named Society again began active operations, and as a result of their efforts a large provisional committee of employers of labour and other influential gentlemen has been formed, with the view of carrying on the work. The arguments adduced in the Committee's circular are such as to leave no doubt that the accommodation they ask is most urgently needed. It is scarcely credible that a district teeming with workshops and factories, having a population of over 200,000 people, largely of the working and indigent class, should be without a single hospital bed or a general public dispensary; or that patients coming from the southern suburbs and from the country towns beyond, suffering from severe accident or serious acute disease, should have to be jolted for many miles on the way to hospital, an experience which doubtless frequently makes all the difference between life and death to the sufferer. Large as the existing hospitals on the north side of the river are, they often fail, even in summer, to afford the accommodation required, and in winter their doors are besieged daily by a crowd of applicants, sometimes two hundred in number, waiting their turn for admission. The wealthy men of Glasgow are always ready to give freely for charitable and benevolent objects; they have a reputation to sustain in this matter, and it is indeed seldom that they have such a strong case presented to them. They will belie the estimate formed of them if they do not soon raise the comparatively small sum, £20,000, required to float this scheme.

The Glasgow sewage question is still unsolved. It has engaged the attention of successive town councils for a number of years, but no satisfactory conclusion has yet been come to. Meantime, the state of the river Clyde, the harbour, and the shores of the upper part of the Firth, is becoming daily worse. A short time ago the endemic prevalence of "influenza" (which in many respects resembled typhoid fever) in Helensburgh and the Gareloch district was attributed, and apparently with justice, to the deep deposit of decomposing mud and sewage brought down from Glasgow, and left on the adjacent shores. The latest suggestion as to the disposal of the city sewage comes from Dr. W. Wallace. In a paper read by him before the Philosophical Society of Glasgow he recommends the precipitation process, and considers lime the least precipitating agent obtainable at a reasonable expense. Alumina is better, but is much more costly. About forty tons of lime would be needed daily for the treatment of forty to seventy million tons of liquid sewage, at a cost of rather less than £9000 per annum. The effluent from this precipitating process, though not perfectly clear and pure, would not, under any circumstances, give rise to a nuisance. Dr. Wallace also announced that a new precipitation process, cheaper to work and giving even better results, would soon be made public.

In the recently-issued annual report of the Glasgow Western Infirmary it is announced that during the past year 12,782 out-door and 2052 in-door patients have been treated, an increase of 1861 on the numbers of the previous year. The number of in-door patients waiting for admission *averaged*, throughout the year, 68. The large addition to the infirmary, which is being built and equipped from funds left for this purpose by the late Mr. Freeland of Nice, and which nearly doubles the accommodation of the institution, is now almost ready for occupancy; but, as shown in the report, the managers depend entirely on increased contributions from the public to enable them to maintain any increased number of patients. Each additional bed occupied will cost about £50 per annum.

A public meeting of the inhabitants of Dundee was held on 29th December, for the purpose of devising means for the establishment of a College in that town. Towards this object there has already been received a sum of £150,000, the gift mainly of Miss Baxter, of Ellangowan, and Dr. J. B. Baxter. The proposed College is for the promotion of the higher branches of education in arts and science: Classical literature, Latin and Greek, pure mathematics, natural philosophy, mental philosophy, and natural science, including chemistry, physiology, natural history, geology, and botany. It has been suggested that medicine also should be taught at the College, and that the large and admirably-conducted Infirmary of Dundee would be of great use in connexion with a medical school. It is anticipated that in time Dundee College will come to be affiliated with one or other of the Universities, and that its classes will qualify for graduation. This rather complicates matters for Scotland's oldest University, St. Andrews, which has already difficulties enough to contend with. Indeed, it has been proposed, and we believe the scheme is at present under consideration, that the Arts and Science Faculties of St. Andrews should be at once transferred to Dundee, a change which could scarcely fail to be of benefit to all concerned.

The new building in which the work of the Glasgow Maternity or Lying-in Hospital will in future be carried on has now been completed, and appears to embody all the latest improvements in hospital construction. It consists of three storeys and attics. Two whole flats are devoted to the wards and head-nurse's rooms, each flat containing eighteen beds, and giving an average of 1460 cubic feet to each patient. In the upper flat an isolation ward is provided, to be used in the event of the breaking out of any epidemic disease. The remainder of the space is taken up by the lecture-room, lecturer's retiring-room, board-room matron's, house-surgeon's, and nurses' accommodation, &c. The sanitary arrangements are as nearly as possible perfect. The lavatories, which contain baths, W.C., washhand basins, slop-sink and general sink, are fitted up with the best and most approved appliances, and are entirely disconnected from the main building, being approached through a lobby with doors at each end. The soil-pipes, traps &c., are thoroughly ventilated. The heating is by open fireplaces and low-pressure hot-water pipes carried through all the wards, lecture-room, staircase, &c. Fresh air, warmed by passing over hot-water pipes, is admitted at the level of the floor, under the windows. The vitiated air is carried off by openings in the wall close to the roof, these being connected by separate flues with a hot-air extracting chamber. The public of Glasgow have subscribed liberally towards the hospital; but we understand that the sum of £1100 is still needed to open the building on a satisfactory footing. This sum will doubtless soon be obtained for such a deserving object.

A vigorous letter from Mr. Thomas Keith appeared in the *Scotsman* of January 3rd. It should be carefully pondered by every sympathiser with anti-vivisection movements, if, indeed, such persons could be induced to give calm and dispassionate consideration to such a subject. It furnishes, also, a fresh instance of the objectionable means to which unreasoning enthusiasts often resort in endeavouring to propagate their beliefs.

THE committee appointed by the Epsom Board of Guardians, to consider the question of the salaries of the medical officers of the union, have recommended an increase in the remuneration for the work done in several of the districts, and that a fixed sum be paid annually to the medical officers for expensive medicines instead of these being charged for quarterly.

IRELAND.

(*From our own Correspondent.*)

DR. CHRISTOPHER FLEMING, an Ex-President of the Royal College of Surgeons in Ireland, and formerly a member of the Surgical Court of Examiners, and surgeon to the Richmond Hospital, died last week in his 81st year.

The Lord Mayor of Dublin, who was installed on the 1st inst., referred to the large expenditure (£22,000) during the past year upon the city sewers, and when the works now in progress (estimated to cost £8000) are finished, he believed the sewerage of Dublin would be in a very perfect condition, at least as perfect as it could be said to be until the larger scheme of main drainage has been carried out. Another satisfactory work had been performed in the purchase of the Coombe area. The district referred to had been a nest of tumbledown, ruined, and filthy tenements, the focus and seat of disease and dirt. It has now been cleared and handed over to the Artisans' Dwellings Company, who have commenced the erection upon it of a large number of suitable and commodious dwellings for artisans and labourers, who will thus be provided with wholesome, convenient, and economical residences supplied with all proper sanitary accommodation. The Plunket-street area is also to be cleared, and although the expense is great, such an immense improvement from a sanitary, social, and moral point of view, is most desirable.

In consequence of a promise by the Chief Secretary for Ireland that certain charges made against the management of the Belfast Workhouse by Mr. Moore, M.P., for Clonmel, should be thoroughly sifted, the Local Government Board for Ireland recently instituted an inquiry into the condition of that institution in reference to the discipline and classification of its inmates, the rate of infant mortality, and the accommodation for the destitute poor. The inquiry was conducted by Mr. Bourke and Dr. Brodie; and last week their report was furnished to the Belfast guardians. They state as the result of their investigation that they found the workhouse very well managed as a rule, the hospital for infectious diseases and the schools being specially worthy of praise for their admirable and efficient condition. The classification of the inmates, as regards the separation of the sexes, was found to be sufficiently perfect and complete; and the rate of infant mortality was equal to 27·9 per cent., which was not unusually high, when the habit prevalent among mothers of taking their infants out of the house as soon as they (i.e., the mothers) are able to move, and then returning, is considered. The charges put forward by a magistrate, and referred to in Parliament, that the workhouse was "a nest of drunkenness, immorality, and crime," have been proved to be without foundation.

Typhus fever is rather prevalent at present in Dublin, and for this additional reason it is absolutely necessary that cases of the disease occurring in tenemental dwellings, where accommodation is not sufficient, and the chance of infecting others is greatly increased, should be promptly removed to hospital. Recently a case of inattention on the part of a dispensary medical officer in Dublin to this wise procedure came under the observation of the Public Health Committee of the Corporation; where in one tenement house several cases of typhus fever had taken place, and the medical attendant had not enforced their removal to hospital. His explanation was not deemed sufficient by the Committee, who considered that it was his imperative duty to report the cases to them; and this view of the matter was acquiesced in by the Local Government Board, who, in a recent correspondence with the gentleman in question, stated that the Committee should have been informed of the fact of such an outbreak of a dangerous infective disease.

By the 20th section of the 43rd and 44th Vic., cap. 13, of the Births and Deaths Registration Act (Ireland), 1880, which came into operation on the first day of the present year, every registered medical practitioner who has been in attendance during the last illness of a deceased person is required to give a certificate stating, to the best of his belief, the cause of death. Refusal to give such certificate entails a penalty not exceeding forty shillings.

The Bangor Town Commissioners have applied for a loan of £14,000, to enable them to carry out a water and sewerage scheme, &c., and the 25th instant has been arranged for the holding of local inquiry into the matter.

Mrs. Sarah Green died on Christmas Eve, at Tullabeg, Coalisland, at the alleged age of 101 years.

Deputy Surgeon-General J. L. Jameson has been appointed principal medical officer at Cork, in succession to Surgeon-General Thompson, now principal medical officer in Ireland.

THE GARRISON HOSPITAL OF HAMBURGH-ALTONA.

(*From a Correspondent.*)

IT is a much-disputed question in Germany whether the "corridor," the "pavilion," or the "barrack" system for hospitals is the best. Having been most kindly shown over one of the best and newest "corridor" hospitals in the empire, a short sketch of it may not be uninteresting.

The Garrison Hospital of Hamburgh-Altona is of red brick, three-storeyed, and contains 212 beds; central entrance, staircases stone. It stands in a garden and is surrounded by fields and open country, facing south. The two upper floors contain the wards, the lower offices, pharmacy, medicine, and surgical appliance; depôt for the whole corps, the ninth; two wards for sick officers, with servants' rooms attached; rooms for the hospital attendants, a small operating room, &c. The hospital orderlies, men detached from their regiments, and having subsequently undergone one year's training, sleep on barrack beds, iron bedsteads with planks, straw mattresses, &c., six in each room; each man has the usual barrack lock-up cupboard. The two upper floors are divided into three "stations"—surgical, medical, or "external" and "internal," and the third for venereal, eye, and skin diseases. Of venereal patients the division contained but few, the supervision of the police under the Contagious Diseases Act having lately become much stricter, the number of venereal cases has decreased in consequence. With one exception, the wards contain only six beds, with an allowance of 1200 cubic feet of air for each patient. The doors opening on to the corridor are numbered, and marked with the cubic contents of the room. Numerous and large are the windows of the corridor, as also those of the wards. These latter are provided with curtains. The whole building is supplied with gas and hot and cold water, the latter being laid on to different parts in the corridor for the patients' use. Floors polished wood. Bedsteads iron, with wire-wove mattress, with head-piece, on which lies another of horsehair. These are most comfortable beds. As also at Metz, the venereal patients here have to be satisfied with a less agreeable arrangement, lying as they do on seaweed mattresses placed on boards. One double bedside table with folding doors stands between every two beds. Two wooden washhandstands with metal basins for each ward. Black bed-head board and clothing the same as at Metz. Latrines—waterclosets, the opening of the door admitting water; urinals with constant supply of water. On each floor is a room specially set apart for smoking (nowhere else is it permitted); also a bath-room with full-length baths; a vapour-bath with cooling chamber, bed, and stove for warming linen; a small kitchen for making poultices, drinks, &c., the heating being done by steam. The upper floor contains quarters for the resident assistant-surgeon—one month on duty; the second a large operating room, a chapel, and a dark room for ophthalmoscopic examinations. The whole building is warmed, both with hot water and warm air, by means of a boiler and steam-engine in the basement. The water, contained in a series of coiled metal pipes lying in a very large brick oven, is heated to about 200°; it then rises to reservoirs in the ceiling of the upper floor, whence it is distributed by numerous small pipes into the warming apparatus proper of the wards and corridors. This consists of six or eight metal pipes, each of about four inches diameter, arranged perpendicularly in a circle, though not actually in contact, and communicating only at the top and bottom. These hot-water "stoves" stand one in each ward, and several in the corridors, reaching almost from the floor to the ceiling. The water, after passing through these, runs out again through a small pipe at the bottom into reservoirs under the floor, whence once more it finds its way in the same manner through the wards and corridors below, and so on again back into the boiler, after warming the first floor, to commence its rounds once more. It is of course evident that the temperature of the upper floor must be higher than that of the second, and this higher than that of the first; and it is found that the water, when it returns to the basement from its transit through the building, has lost about fifty degrees of heat. The wards are further warmed, as also ventilated, by means of a large wheel, shaped like a ship's screw, worked by a steam-engine. It rotates below the basement floor, draws in the external air through a high chimney built at some distance from the building, and communicating with it by means of a subterranean passage. In winter the air is passed over a series of pipes heated by steam, and then forced into the different wards through shafts contained in the walls dividing the rooms from corridor, communicating with the wards by valved openings near the floor, and others near the ceiling opposite the windows. In summer the air is not previously warmed. Near the windows are louvred openings communicating with the outside through ventilating shafts. The amount of air admitted can be regulated by a contrivance from the corridor; cold air can be supplied through one, and hot air through the other, opening into the ward at the same time. The cooking is by steam, in metal boilers cased with wood. These are the chief points of interest in this "model" hospital.

I add the following extract from the last *Décret*, June 15th, 1880, relating to appointments in the Medical Department of the French Army.

In every September an examination will be held for candidates for the Medical Department of the army, the primary conditions being the following:—All candidates must be born or naturalised French subjects. Those already doctors of medicine not to be more than twenty-six years of age; students of medicine not to be more than twenty-five years of age, but not less than twenty-two. An engagement to serve in the department for at least ten years from the date of being appointed assistant-surgeon of the second class. It is ordered that, in future, appointments be open to doctors and students of medicine of sixteen, twelve, and eight "inscriptions" (courses of lectures attended), who shall have passed the corresponding examinations. Those considered qualified and commissioned as candidates for the department—in numbers as required—are divided into two classes, the first composed of students merely, the second of those who have already taken the degree of doctor. Candidates of the first category will have to undergo the same education and the same examinations as civilians for the title of doctor of medicine—three years. They may choose their place of residence and study from among eleven cities in France, Paris included, named in the *Décret*. Attached to a military hospital, or to the military division of a civil hospital, under the orders and surveillance of the surgeon-in-chief, they will assist in the hospital work, and at the same time follow the complete course of lectures and general study, &c., of the school in which they are inscribed. The candidates do not wear uniform, but are under a certain discipline, and receive a fixed yearly sum of 1200 francs for their general expenses and the purchase of the necessary books and instruments. Should the student fail in his examination twice, he will be dismissed, and repay all moneys advanced by the State. Candidates of the second class, doctors of medicine, enter the School of Military Medicine, Val-de-Grâce, with the title of "stagiaires," at once, on the condition of their being passed bodily fit for the service. They draw 2000 francs per annum, wear uniform, obtaining a grant for their first outfit. While at the school they are made familiar with medicine and surgery as applied to the army, theoretically and practically, also with official work and routine. The course to last at least eight months. After a successful examination, these "stagiaires" become "aides-major," or assistant-surgeons of the second class.

THE Municipal Council of Paris has, it is reported, voted a sum of £400 for the establishment of a School of Chemistry, which will be free to the pupils of the municipal schools who are desirous of practice in chemical industries. The smallness of the sum is noteworthy.

Obituary.

CHRISTOPHER FLEMING, M.D., F.R.C.S.I.

THIS gentleman died on the 30th ult. at Donnybrook, County Dublin, aged eighty years. Dr. Fleming had for some years retired from practice, but formerly held the appointment of visiting surgeon to the Richmond Hospital, and was a member of the Surgical Court of Examiners in the Royal College of Surgeons in Ireland, of which institution he was president in 1859–60. Deceased was a graduate in Arts and Medicine of the University of Dublin, consulting-surgeon to Steevens's Hospital, a member of the Royal Irish Academy, and formerly corresponding member to the Surgical Society, Paris. He was the author of some medical papers, including one on the subject of chloroform in surgery, and published in 1877 a work entitled "Clinical Records of Injuries and Diseases of the Genito-urinary Organs."

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — The following gentlemen were admitted Licentiates of the College on Dec. 30th :—

Allen, Thomas William James, University Hospital.
Bathe, Anthony John, Whittington Villas.
Bull, Geo. Coulson Robins, London-street, Paddington.
Carpenter, Arthur Bristowe, Duppas House, Croydon.
Grayling, Arthur, Forest Hill.
Harvey, Sidney Frederic, Catherina-terrace, Lansdowne-road.
Macdowall, Cameron Joseph Francis Stuart, Osnaburgh-street.
Maynard, Foster Fowler Martin, St. Andrew's Park, Hastings.
Mills, Thomas Wesley, M.D. McGill, Murray-street.
Patten, Charles Arthur, Marpool House, Ealing.
Pearce, Walter, Oxford-terrace, Edgware-road.
Phillipps, William Alfred, Longton-grove.
Renshaw, Israel James Edward, Sale, Manchester.
Wilkinson, Frank Tichborne, Dean-street.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 5th inst. :—

Charles Slater, Thomas Rushbrooke, and Harry Groom, Cambridge; Edward Paxton and Joseph Whittaker, Owens College, Manchester; John F. G. Dill, Cambridge and Guy's Hospital; Charles W. Thompson, Leeds; Frank Pearse, Guy's Hospital; Albert G. Cunningham, Bristol; William H. Burke, Dublin; Henry S. Wood, Melbourne; Thomas Kelly, McGill College, Montreal; Joseph H. Powell, Bristol.

The Library of the College will be closed on Friday, the 14th, and Saturday, the 15th inst., in consequence of the examination for the Membership.

UNIVERSITY OF DURHAM. — The following name should have appeared in the list published in our issue of Dec. 18th of gentlemen who had conferred on them the M.D. degree :—

Bedford Fenwick, M.B., M.R.C.S.

LONGEVITY OF MEDICAL MEN.—The calendars of the Royal Colleges of Physicians and Surgeons, London, give some rare examples of longevity amongst their fellows and members—viz.: Archibald Billing, F.R.C.P., of Park-lane, completes his ninetieth year on the 10th inst.; Joseph Hurlock, F.R.C.P., of Brighton, is eighty-eight; Sir Thomas Watson, Bart., F.R.S., D.C.L., eighty-eight; Alexander Tweedie, F.R.S., F.R.C.P., eighty-six; James Arthur Wilson, F.R.C.P., of Holmwood, near Dorking, eighty-five; Bisset Hawkins, F.R.S , F.R.C.P., eighty-four; Sir James Alderson, F.R.S., late President of the Royal College of Physicians, eighty; Christopher J. R. Allatt, F.R.C.P., of Dover, eighty; Sir George Burrows, Bart., F.R.S., D.C.L., late President of the Royal College of Physicians, seventy-nine; James Muscroft, F.R.C.S., of Pontefract, ninety-five; T. M. Greenhow, F.R.C.S., of Leeds, ninety; Robert Tayler, F.R.C.S., of Brighton, ninety-one; James Moncrieff Arnott, F.R.S., late President of the Royal College of Surgeons of England, eighty-seven; John Flint South, F.R.C.S., of Blackheath, eighty-four; Cæsar Henry Hawkins, F.R.S., F.R.C.S., Serjeant Surgeon to the Queen, of Grosvenor-street, eighty-three; James Luke, F.R.S., F.R.C.S., Consulting Surgeon to the London Hospital, eighty-three; Robert M'Cormick, R.N., F.R.C.S., Deputy Inspector of Hospitals and Fleets, eighty-three; this gentleman accompanied Sir Edward Parry as Assistant Surgeon in Her Majesty's ship *Hecla* in the attempt to reach the North Pole in 1827.—*The Daily Telegraph.*

MR. JOHN DUNCAN, a weaver, has presented to the University of Aberdeen a collection of botanical specimens, which he had accumulated with his own hands, and which is stated to be unique in respect of its value and completeness.

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. The late Sir Thomas Hare, Bart., of Stow Hall, Norfolk, bequeathed a legacy of £100 to the West Norfolk and Lynn Hospital.

PRESENTATION. — Dr. John Finigan, of Addison Lodge, Glasnevin, county Dublin, has been presented with an address and a valuable service of solid silver plate.

THE Fishmongers' Company have made a grant of 100 guineas towards the cost of the new buildings at St. Bartholomew's Hospital.

THE salaries of Dr. Brett, medical officer to the Union house and district of Watford, have been increased from £55 and £70 to £70 and £100 per annum respectively.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest.*

BENTHALL, W., M.R.C.S.E., has been appointed House-Surgeon to the Derbyshire General Infirmary, vice Hough, resigned.

DOBSON, A., L.R.C.S,., L.R.C.P., has been reappointed Medical Officer for the West District of the Holbeck Union.

DONKIN, W. F., M.A., has been appointed Public Analyst for the County of Wilts.

EVERARD, H. N., M.B., has been appointed House-Surgeon and Apothecary to the Leicester Infirmary and Fever Hospital, vice Moore, resigned.

HOOPER, C., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health to the Aylesbury Rural Sanitary Authority.

HUMBLE, G. A., M.D., M.R.C.P.L., has been appointed (*pro tem.*) Physician to his Excellency the Governor of Patagonia (South America) and Staff, vice Dr. Baraja, deceased.

HYSLOP, J., M.B., C.M., has been appointed Assistant-Physician to the Royal Edinburgh Asylum, Morningside.

LEITCH, J., M.B., C.M., has been reappointed Medical Officer of Health for the Holme-Cultram Urban Sanitary District, Cumberland.

LONGFORD, H., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Thirsk District and the Workhouse of the Thirsk Union, vice Ryott, deceased.

MALLINS, H., M.B., C.M., has been appointed Medical Officer to the Walton District of the Wayland Union.

MANBY, A. R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Reedham District of the Docking Union.

MOORE, Mr. E. H., has been reappointed Public Analyst for the Eastern Division of the County of Sussex.

PADDISON, E. H., M.B., has been appointed a Junior Assistant Medical Officer to the Surrey County Lunatic Asylum, vice Hosking, resigned.

PATTINSON, J., F.C.S., has been appointed Public Analyst for the Borough of Gateshead.

PAYNE, C. A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of the Workhouse, Shoreditch Union, vice Hargreaves, resigned.

POTTER, H. P., F.R.C.S., M.R.C.S.E., L.S.A.L., &c., Medical Registrar of St. Thomas's Hospital, has been appointed Resident Medical Superintendent to St. Mary Abbott's, Kensington, at a salary of £300 per annum, rising to £350 after the first year, with house &c., vice W. B. Whitmore, M.B., resigned.

REDWOOD, T., Ph.D., has been reappointed Public Analyst for the Parish of St. James and St. John, Clerkenwell.

STODDART, Mr. F. W., has been appointed Public Analyst for the City of Bristol, vice W. W. Stoddart, deceased.

TOWLSON, H. J., M.R.C.S.E., has been appointed Medical Officer to the Barrowden District of the Uppingham Union.

VACHER, F., F.R.C.S., has been reappointed Public Analyst for the Borough of Birkenhead.

WALTER, W., M.D., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Honorary Surgeon to St. Mary's Hospital, Manchester, vice Heslop, resigned.

WELLS, A. G., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Third District of the Fulham Union.

Births, Marriages, and Deaths.

BIRTHS.

Buck.—On the 2nd inst., at Ryde, the wife of Thomas Alpheus Buck, M.B. Lond., of a son, stillborn.

Colenso.—On the 28th November, at Durban, Natal, the wife of Robt. J. Colenso, M.B., M.R.C.S.E., of a son.

Constable.—On the 2nd inst., at Kennington-park-road, the wife of Joseph J. Caffry Constable, M.D., of a son.

Holland.—On the 27th ult., at Maida-vale, W., the wife of J. Holland, M.D., of a daughter.

Kisch.—On the 31st ult., at Sutherland-gardens, Maida-vale, the wife of Albert Kisch, M.R.C.S.E., of twin sons.

Randell.—On the 2nd inst., at Vanbrugh-park, Blackheath, the wife of E. B. Randell, M.R.C.S.E., L.D.S., of a daughter.

Tredinnick.—On Christmas Eve, the wife of Ernest Tredinnick, of Strefford, Craven Arms, of a daughter.

MARRIAGES.

Barlow—Dalmahoy.—On the 30th ult., at 69, Queen-street, Edinburgh, by the Rev. A. Whyte, M.A., Thomas Barlow, M.D., F.R.C.P., to Ada Helen, daughter of the late Patrick Dalmahoy, Esq., Writer to the Signet.

Gamlbe—Shipley.—On the 28th ult., at St. Peter's, Eastgate, Lincoln, Ernest G. Langwith Gamble, L.R.C.P.L., to Emmeline, youngest daughter of G. H. Shipley, of Lindum House, Lincoln.

Hayward—Mackenzie.—On the 30th ult., at Union Chapel, Oxford-street, Manchester, by the Rev. Alexr. McLaren, D.D., Thos. Ernest Hayward, M.B. Lond., F.R.C.S.E., of Haydock, Lancashire, to Catharine, only daughter of Melville Mackenzie, of Edinburgh.

Jones—Reeder.—On the 30th ult., at Wath-upon-Dearn, by the Rev. John Jones, Vicar of Blaenavon (father of the bridegroom), assisted by the Rev. H. Partington, Vicar, William Makeig Jones, of Wath, to Annie Tofield, only daughter of Thomas Reeder, of Wath.

DEATHS.

Buck.—On the 29th ult., at the County Lunatic Asylum, Leicester, John Buck, M.R.C.S., for twenty-eight years Medical Superintendent of that Asylum, aged 64.

Evans.—On the 31st ult., at Rome, of typhoid fever, George Harrison Evans, M.B., F.R.C.S., of Chad-road, Edgbaston, elder son of the late G. F. Evans, M.D., F.R.C.P., Birmingham, in his 36th year.

Neylan.—On the 10th November, at Bowral, Sydney, New South Wales, John Desmond Neylan, M.R.C.S.E., L.S.A.L., Order of Medigié (Fourth Class), of County Clare, Ireland, in his 30th year. R.I.P.

Prentice.—On the 29th ult., at his son's residence, Campbell-road, Bow, Alfred Prentice, M.D., in his 76th year.

White.—On the 29th ult., at Duncan-terrace, Newington, Edinburgh, William Alexander White, M.D., F.R.C.S.E., Deputy Surgeon-General (Retired), Army Medical Department.

Whyte.—On the 2nd inst., at Clifton, Bristol, Charles Whyte, Inspector-General of Army Hospitals, aged 85.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

INTERNATIONAL MEDICAL CONGRESS.

London, August 2nd to 9th, 1881.

SECTION XIV.—MILITARY SURGERY AND MEDICINE.

Surgeon-General Prof. Longmore, C.B., President.

Sir William Muir, M.D., K.C.B., Director-General, Army Med. Dep.
Surgeon-General Sir Joseph Fayrer, K.C.S.I., M.D., LL.D., F.R.S., India Office,
Dr. J. W. Reid, Director-General, Med. Dep. of Navy,
Vice-Presidents.

Dr. W. H. Lloyd, Fleet Surgeon, R.N.,
Surgeon-Major Sandford Moore, Aldershot,
Surgeon A. B. R. Myers, Coldstream Guards,
Secretaries.

Proposed List of Subjects for Discussion, subject to revision before 31st December, 1880.

1. By what arrangements can the practical difficulties in the way of employing antiseptic surgery (Listerism) in the treatment of wounds inflicted in the field in time of war be most readily overcome? [The discussion to include (*a*) the system on which the treatment can be most efficiently carried out; and (*b*) the fittest material means to be employed in it, under the circumstances in which armies are placed while on active service.]

2. To what extent, and in what special directions, has conservative surgery advanced in field practice, as shown by statistical results of the treatment adopted for gunshot wounds during the wars of the last ten years? and what indications have been afforded, if any, by the experience gained during this period for making further advances in the conservative treatment of such injuries?

3. What are the most reliable, and at the same time practicable, means of immobilising the parts involved in gunshot fractures of the Spine, Pelvis, and Femur in field practice?

4. On improvements in field hospital and transport equipment, for use with armies moving in uncivilised or partially civilised countries, suggested by the experience gained during the recent military operations by British troops in South Africa.

5. On the prevalence and prevention of Typhoid Fever among young soldiers in India.

Medical Diary for the ensuing Week.

Monday, Jan. 10.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ A.M. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

St. Mark's Hospital.—Operations, 2 P.M.; on Tuesday, 9 A.M.

Medical Society of London.—8½ P.M. First Lettsomian Lecture: Sir Joseph Fayrer "On Tropical Dysentery and Diarrhœa."

Tuesday, Jan. 11.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 3 P.M.

Anthropological Institute of Great Britain and Ireland.—8 P.M. Ordinary Meeting.

Royal Medical and Chirurgical Society.—8.30 P.M. Mr. Knowsley Thornton, "On one hundred and seventy-two Antiseptic Abdominal Sections, with remarks on the causes of death in the fatal cases"; Mr. Frederick Treves, "On a case illustrating the condition of Large Arteries after Ligature under Antiseptic and Non-antiseptic Measures"; Mr. Henry Lee, "On Radical Cure of Varicocele"; Mr. Jer. M'Carthy, "On Aneurism of the Axillary Artery treated by Antiseptic Ligature of third part of Subclavian Artery."

Wednesday, Jan. 12.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Beards and Moustachios.

Enquirer.—It would seem to be dawning on the consciousness of the male population that, after all, beards do not make as effective throat protectors as may be purchased for a shilling, or moustachios the best and most convenient of respirators; while in respect to both these apparatus the natural have to be endured constantly, whereas the artificial need only be employed in times of need or at pleasure. We fear the laborious argument that it was healthful to man to spare himself the trouble of shaving was somewhat strained, and that the wish for a fashionably formidable appearance was father to the thought of healthfulness as regards the wearing of beards and moustachios. The number of persons returning to the old English practice of shaving both the chin and the upper lip is noticeably increasing, and there is certainly much to be said for the clean and orderly character of the result. It is, at least, a remarkable circumstance that throat affections have not died out, or, we believe, sensibly diminished, since the custom of growing the beard became general. It must in the long run be a matter of personal predilection whether a man shaves or leaves his face embellishment to nature. It is practically in this case, as in most others, idle to seek an argument in favour of the vagaries of fashion in the code of health laws.

ESCAPE OF WORMS BY THE EXTERNAL MEATUS.

To the Editor of The Lancet.

Sir,—A few weeks ago I saw a case reported in your journal of rupture of both tympanic membranes by the common round worm, the worms making their escape, one by the right, the other by the left external ear. I have had lately a somewhat similar case under my care, in which the right tympanum was ruptured, giving rise to a good deal of hæmorrhage and slight deafness, the worms, three in number, escaping by the external meatus.

Yours truly,
Beeford, Hull, Dec. 14th, 1880. Jno. Dickson, M.B.

Mr. James Robertson.—We are unable to answer the question.

OPIUM CRAVING.

To the Editor of The Lancet.

Sir,—Would any of your readers who have had experience in the treatment of opium-eaters be so good as to give me the most suitable remedy or remedies for the relief of the craving in a patient of mine who has been in the habit of taking the drug for twenty-eight years, at times as much as one and a half drachms per diem? and oblige, yours truly,

C. Clark Burman, L.R.C.P. & S., &c.
Belford, Northumberland.

Insanity in America.

At a recent meeting of the Council of the National Association for the Protection of the Insane and the Prevention of Insanity, held at New York, the President, Dr. H. B. Wilbur, stated there were at least 50,000 insane persons in the United States, and that of these one-half were in State asylums or hospitals, about 2000 in incorporated or private institutions, about 7000 in city or county asylums, and some 16,000 in county poor-houses or in the custody of friends. The object of the above Association is to bring about an improved method of treatment of the mentally unsound, by directing attention more to the cure of the malady than to the restraint of its victims.

TONGA.

To the Editor of The Lancet.

Sir,—I have a letter before me dated Fiji, September 7th, 1880, written by a gentleman long a resident in the country to his father in England. As this gentleman seems to know a great deal about the discovery of tonga, I shall, with your permission, give an extract or two from his letter. The history of the discovery of tonga which he gives differs somewhat from that mentioned by Dr. Bancroft, as stated in Mr. Christy's letter in your impression of December 4th.

The letter says, "At Lau, in Lomaloma, the windward portion of this group, has resided for many years a Mr. Veccey, a Hungarian gentleman, married to a half-caste Tongan wife. For above two years he suffered so much from neuralgic pains in the head that he went almost mad at times. His wife persistently stated that the Fijians could cure him, but some latent fear of poison for a long while operated to prevent his trying any native medicine. Finally he acceded to his wife's entreaties, and consented to try the natives' remedies, but conditionally that the medicine should be shown to him before he took it. During two years Mr. Veccey took and tried no less than fifty-five different medicines—the juices of leaves, barks, and roots—all of which he would only take after seeing the plant or tree from which they were taken, and he obtained on each occasion the native name and took a written note of it.

"From the bulk of these remedies he received no visible relief, nor could he perceive any effect; but from four of them he derived some temporary alleviation from his long-sustained agony. Finally, a medicine was brought to him which in four doses effected a complete and permanent cure.

"One of the Messrs. Ryder of Mango going home, Mr. Veccey entrusted to him a few packages of medicine consisting of the four barks which had alleviated his sufferings and the one that had cured him, so cut up and mixed as to defy discovery, nor did he entrust the secret to Mr. Ryder. He simply requested Mr. Ryder to endeavour to ascertain if the medicines contained any new and unknown valuable properties, and, if so, if he could make a commercial speculation of them.

"I may add that the barks are cut to shreds and mixed to prevent discovery, and every effort here is used to keep them a secret."

The name "tonga" was given to the combination of barks in obedience to the wishes of Mr. Veccey's wife.

I am, Sir, yours truly,
Lincoln, Dec. 10th, 1880. W. O'Neill, M.D., M.R.C.P. Lond.

To the Editor of The Lancet.

Sir,—I sent you a few days since a letter upon tonga, and some remarks made by Dr. Bancroft upon Alstonia constricta, stating that he used it in Australia for fevers, &c., and found it as efficient as quinine.

I have just received from Dr. O. Hesse of Feuerbach (to whom I sent a supply of Alstonia constricta some time since for the purpose of investigation) a valuable paper of his in Liebig's "Annalen der Chemie," Band 205, pp. 360–371, in which he describes at length two alkaloids that he has obtained from the bark—viz., alstonia and alstonidin.

I trust that the value of these alkaloids will soon be tested in this country by physiologists, as will no doubt be the case in Germany before long. An alkaloid which would replace and be equal to quinine in its effects, but be obtainable at a lower price, would be a boon in many parts of the globe. I may add that I believe that Dr. Hesse is analyst for Messrs. Jobst, one of the largest quinine manufacturers in the world.

Yours truly, T. Christy, F.L.S.

Dr. J. M'Grigor Maclagan.—The report may be obtained on application to the present medical officer of health of the district.

GLACIALINE.

To the Editor of The Lancet.

Sir,—I have read with no little surprise the letter in The Lancet of January 1st, signed by two members of the profession, extolling the virtues of glacialine. All that the writers state may be perfectly true, and probably is so; but what is glacialine? Some time since a medical friend bought in Glasgow a box of this powder, and as its use was recommended for the preservation of every edible substance, he thought it desirable to know its nature and properties, and for this purpose sent some of it to me for analysis, the result revealing it to be pulv. sodæ biboracis pure and simple.

The moral I wish to convey here is that we (the English people) are at present having such a flood of these "frivolous" things puffed and advertised and put into the channels of business, and recommended for every mortal ill, that it is high time to stem the tide, if it be possible. It is astonishing what virtues a substance possesses when it is not known what it is.

Yours faithfully,
Jan. 3rd, 1881. F. M. Rimmington, F.C.S.,
Public Analyst.

EATON *v.* BARKER.

A CORRESPONDENT writes to us:—

"In your annotation of the case of Eaton *v.* Barker and others you say 'If the people of Grantham will allow Mr. Eaton to be thus deprived of his legitimate fees, &c., it will be incumbent upon the profession to interfere in his relief.'

"Would it not be better for the profession to take the lead, and show the newly organised corporation of Grantham what we think of Mr. Eaton's conduct in undertaking the risky duties, for which he claims but very reasonable remuneration?

"No doubt there will be many right-minded people in Grantham, although they are indifferently represented in the corporation, and these will be influenced by the very significant judgment delivered by Mr. Justice Stephens; but I think we ought to move in the matter ourselves, and, in order to facilitate the movement, I beg to suggest that a medical officer in each union should collect what subscriptions he can from his professional brethren, and remit them to you in lump sums, to be presented to Mr. Eaton, with a suitable address setting forth the motives of the subscribers.

"I shall be happy to receive subscriptions in my union and to include my mite, whether you adopt my suggestion, or whether you propose an amendment to it."

"TEMPERAMENTS."

To the Editor of THE LANCET.

SIR,—The note on "Temperaments" in your issue of December 4t having made me desirous of reading up the subject, I shall be greatly obliged by you or any of your numerous readers naming the best sources of information, whether in connexion with medicine, or as a part of general knowledge.—I am, Sir, yours truly, F.R.C.S.E.
December 15th, 1880.

A Provincial House-Surgeon.—1. No.—2. The coroner is bound to issue his summons in accordance with a prescribed form.

FATAL MIDWIFERY CASE IN PRIVATE PRACTICE.

To the Editor of THE LANCET.

SIR,—I send you notes of a fatal case of labour which took place under my care lately. I often think that if, instead of our successes, our failures were recorded, they would be much more instructive.

Mrs. W——, aged twenty-five, a fine, healthy, well-made young wife, began in labour for her second child at midnight of December 18th, 1880. I was sent for at 12.30, found all going on well, and at 2 A.M. a fine female child was born. The placenta came away easily in about ten minutes; the uterus contracted firmly, and remained so. I went upstairs to see her before leaving at 3 A.M. (one hour after delivery). She said she felt quite well, and not a bit reduced; her pulse was 72, of good tone, and the uterus still firmly contracted. I left her with a perfectly easy mind.

At 9 A.M. (seven hours after delivery) I was hastily summoned, and on arriving found her in a state of collapse, and evidently dying. The uterus was firmly contracted; there was and had been no hæmorrhage; the body, extremities, head, tongue, and breath were absolutely cold; not the faintest pulse in either wrist, and only a faint, flabby, second sound over the heart; the face and hands were livid; intense pain referred to the epigastrium and extreme—very extreme—dyspnœa; and although her lungs evidently filled well with air, her constant entreaty was for "more breath." Her intellect was unaffected.

I at once came to the conclusion that this was a case of thrombus of the pulmonary artery, and having given her a strong stimulant with a dose of sedative solution of opium to ease her pain, I sent for my able and experienced colleague, Dr. Robinson, who came at once, and on examination entirely concurred in my view of the case. We gave stimulants (ether and ammonia) freely, with hot bottles and friction to the limbs, with the view of rousing the heart and forcing the circulation, in the faint hope that possibly the plug might be broken up and forced into the smaller pulmonary arteries (ending in the lesser evil of infarction of the lesser arteries of the lungs), but without avail, as she quietly died about 10 o'clock (one hour after I was sent for). She was a very healthy girl, with no history of rheumatism or other disease.

Comment or speculation on the case from me is needless.

Yours very truly,
JAMES J. B. TAYLOR, M.B.
Lightburne House, Ulverston, Dec. 23rd, 1880.

Mr. Myers.—Any registered surgeon would advise on the subject.

RETREATS FOR DIPSOMANIACS.

To the Editor of THE LANCET.

SIR,—Can any of your readers either tell me or put me in the way of learning whether any retreat for dipsomaniacs has been opened anywhere in England under the provision of the recent Habitual Drunkards Act, such that a patient, on previously signing his consent, may be actually compelled to remain for some period?

I do not see any such advertised in the columns of THE LANCET.

I am, Sir, yours truly,
Nottingham, Jan. 4th, 1881. PHILIP J. SMITH.

EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE first examination for the present session in Anatomy and Physiology for the Diploma of Membership of the College was commenced on Monday last, when 146 candidates presented themselves, being six in excess of the corresponding quarter last year. The following were the questions on Anatomy submitted to them, when they were required to answer four, and not more than that number, out of the six questions:—

1. Describe that portion of the innominate bone which lies internal to a line drawn vertically through the centre of the obturator foramen.
2. Describe the palmar fascia. What structures lie superficial to it, and what are exposed upon its removal?
3. Describe the attachments of the quadratus lumborum. Mention the structures with which it is in relation.
4. Describe the course and inosculations of the anastomotica magna arteries in both upper and lower extremities.
5. What are the structures which form the root of the lung? Describe the relative position of these structures to each other, and the anatomical relations of the root of the lung on both sides of the thorax.
6. Enumerate the nerves supplying the skin and muscles of the scalp, and mention the sources from which they are derived.

The following were the questions on Physiology:—

1. In what manner is urine secreted? By what circumstances are its quantity and quality affected in health?
2. Describe the course of the blood in the fœtus. State the changes which the fœtal blood undergoes in the placenta.
3. What is glycogen? Where is it formed in the human body? From what materials is it formed?
4. Describe the structure of the skin and its glands.
5. Describe the structure and extent of the olfactory mucous membrane. Describe the conditions requisite for the sense of smell.
6. How is absorption effected in the small intestine? State what share is respectively taken in the act of absorption by the lymphatics and bloodvessels.

At this meeting the recently elected members of the Board—Messrs. John Langton and Gerald F. Yeo—took part, Mr. Arthur E. Durham presiding.

PARAFFIN JACKETS.

To the Editor of THE LANCET.

SIR,—Your correspondent, "Enquirer," asks for too much if he thinks an apparatus has yet been devised which will effectually draw outwards a collapsed side of the thorax or the curvature of a spine; but, for all that, much may yet be done to prevent the evil from increasing, and to give comfort and support to the patient.

"Enquirer" has tried plaster-of-Paris and the poroplastic material, and condemns both. Let me recommend him to try paraffin wax, which may be obtained at any of Young's depôts, and which, when melted, must be used just in the same way as liquid starch. The bandage, being soaked in the paraffin, should be lightly wound round the patient's body, and will set much more rapidly than starch. It must be slit up with a strong pair of scissors at the back just before it sets, and, if properly smeared with liquid paraffin wax, will form a stiff, elastic, and cleanly mould of the body, which may be removed at pleasure for comfort at night and to allow ablutions in the morning.

I should mention that another garment should be worn next the body (or the skin may be well oiled in case it is not used) in order to prevent the paraffin from adhering, and that no pressure on the ribs can occur if it is properly managed. Indeed, by the use of a pad placed underneath, any part, may be specially relieved, even of its own share of contact with the jacket. Eyelet-holes may be punched in the jacket along the cut margins, and it will then resemble a corset, which can exercise no pressure, whilst it gives universal support.

I am, Sir, your obedient servant,
EDWARD HAUGHTON, M.D.
Spring Grove, Upper Norwood, Dec. 1880.

Query should apply to the registrar of the university.

Indicus and J. S.—Next week.

W. M. D. has forgotten to enclose his card.

FOGS.

To the Editor of THE LANCET.

SIR,—In reference to your article in last week's LANCET on Rain and Fogs, permit me to draw your attention to what many must have experienced, but no doubt overlooked—viz., last summer I was in a fog off Jersey so black that I could not see the man at the wheel, and this in the daytime. Again, on another occasion, in a steamer off Penzance, the captain called us on deck, saying he did not know the moment that we might not have to jump for our lives. When I got on deck I could not see the captain, though I heard his voice, the fog was so black and thick. Certainly this could not be coal smoke or exhalation from London clay.

I am, Sir, yours truly,
Jan. 3rd, 1881. THOS. R. DOWNES.

HIGH-HEELED BOOTS AND SHOES.

To the Editor of THE LANCET.

SIR,—Dr. Pullin deserves the thanks of the public for bringing the above before them, and had he added a few remarks upon another complication in the boots and shoes of the present day, I should have thought it unnecessary to have troubled you. I mean the shortness of the boots and shoes, and also their narrow and pointed toes. Within the last few years, in addition to high heels, we have these abominable narrow toes, which I believe will be the ruin of half the feet of those who are foolish enough to persist in wearing them. By raising the heel two inches from the ground the foot is pushed forward into a short, tight, narrow funnel, and what is the consequence? Corns and bunions in all manner of unusual places, blisters and sores on different parts of the feet, and, worst of all, pressure upon the toenails, and especially those of the great toe, with inflammation and "ingrown toe-nail," with all its accompanying pain and horrors, and sometimes disease of bone.

I daresay almost every general practitioner will agree with me that he has had many more cases of "ingrown toe-nail" since the high-heeled and narrow-toed mania than when people wore sensible boots and shoes.

I remember one lady consulting me, with shame on her part, who had paid a chiropodist quite a little fortune for "medical attendance" on bunions, corns, and ingrown toe-nails. I have no doubt but that chiropodists are very much in request at the present moment, and are doing a good trade at the expense of those (especially ladies) who will have fashionable boots and shoes.

"The voice of the profession," as Dr. Pullin remarks, will, I trust, be raised against the high heels and narrow toes. It is painful to see young ladies striving to walk in these instruments of torture. It is certainly, if they only knew it, far from graceful or elegant. Apologising for troubling you, I am, Sir, your obedient servant,

Leamington, Dec. 1880. FRANCIS WILLIAM SMITH, M.D.

King Blushrose.—Highly objectionable, of course, and altogether unprofessional; but it is impossible to put a stop to this sort of thing, and we do not wish to advertise the "trade" further by noticing it.

One Aggrieved.—Our correspondent is thanked for his communication, but we see no reason to alter the opinion we have expressed.

CORONER'S LAW.

To the Editor of THE LANCET.

SIR,—There are two points connected with the above subject on which I shall be glad to receive information. 1st. Am I bound to make a post-mortem examination whenever ordered by the coroner? 2nd. Am I liable to be summoned and bound in such case to serve as a juror in the coroner's court?

With regard to the first query I can find no authoritative statement. So far as I can make out, under the Medical Witnesses Act I am bound to give my attendance when so required, but am I also bound to make a necropsy, or rather does "attendance" imply doing this? I am not bound to make an analysis of the stomach and its contents, as in view of possible incompetence in that direction. This may be done by an expert. If incompetence is allowed as an excuse in one direction, can it not be pleaded in another? Would not attendance at midwifery constitute incompetence? Surely in the eye of the law every man must be incompetent or unfitted for any kind of work the doing of which will endanger the life of another.

The second question which I put—namely, as to liability of medical men to serve as jurors, arises from the fact that in this neighbourhood several medical gentlemen have been summoned and have attended as jurors. As I always understood that we were exempt for all service of this kind, and as I still so believe, I shall be glad to receive information, lest I should, by acting on this belief, be running into danger.

I remain, Sir, yours, &c.,

Dec. 17th, 1880. W. HENRY KESTEVEN, M.R.C.S.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

A Lecture

ON

THE DIFFERENTIAL DIAGNOSIS OF CARDIAC MURMURS.

Delivered in the Extra-Academical School of Medicine, Edinburgh,

By BYROM BRAMWELL, M.D., F.R.C.P. EDIN.,

LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE, AND ON PRACTICAL MEDICINE AND MEDICAL DIAGNOSIS IN THE EXTRA-ACADEMICAL SCHOOL OF MEDICINE, EDINBURGH; LATE PHYSICIAN AND PATHOLOGIST TO THE NEWCASTLE-ON-TYNE INFIRMARY.

(Concluded from page 45.)

The murmur is endocardial—is it organic or functional?[1]

It is sometimes very difficult, or even impossible, to say whether a murmur is purely organic or purely functional, for, in the first place, the two conditions are not unfrequently combined, as, for example, where anæmia accompanies aortic stenosis or mitral incompetence; and, again, a mere roughness of the endocardium may produce a murmur (an organic murmur, therefore), without causing any disturbance of the circulation or secondary changes in the heart (the usual accompaniments of an organic lesion). In the latter case the diagnosis mainly turns on the following points: (*a*) the presence or absence of the associated conditions of an inorganic murmur (symptoms and signs of anæmia), (*b*) the stability of the murmur, whether it is constant or variable, and (*c*) the effects of treatment. (See below, the Diagnosis of Inorganic Murmurs.)

Practically, the first step in the differential diagnosis is to determine the rhythm of the murmur. The so-called functional murmurs are always systolic, and are either aortic, pulmonary, or mitral.[2] If therefore a murmur is diastolic or presystolic we may, with certainty, conclude that it is organic. If the rhythm of the murmur does not decide the question—i. e., if the murmur is systolic,—we must seek to determine whether it is organic or functional by attention to the following facts:—

1. *The presence or absence of the causes of inorganic murmurs on the one hand, or of organic murmurs on the other.*—Anæmia is the great cause of the so-called functional (inorganic) murmurs. If there is no anæmia the strong probability is that the murmur depends upon organic causes. The presence of anæmia does not, however, prove that the murmur is inorganic, for, as I have previously stated, anæmia and organic murmurs are not unfrequently associated. This caution more particularly applies to those cases in which a patient suffering from rheumatic fever is anæmic. In such a case the probability is in favour of organic mischief, and a guarded prognosis should always be given. In well-marked anæmia there is the characteristic pallor, shortness of breath on exertion, tendency to vertigo and syncope on sudden alterations in position (e.g., rising from the recumbent position, venous hum in the neck, slight œdema of the feet, &c.). Where the anæmia is only slight, the presence of a venous hum (*bruit de diable*) in the neck is very characteristic, and affords important corroborative evidence that the murmur is inorganic. A history of rheumatic fever, or still more the actual presence of rheumatic fever, are in favour of the murmur being organic.

2. *The condition of the heart and circulation.*—Serious organic valvular lesions always give rise to important disturbances in the circulation and secondary changes in the heart, which will be presently described (see below). The presence of such alterations is strong evidence in support of an organic lesion. The absence of such alterations does not, however, prove that the murmur is inorganic, for (*a*) a slight organic lesion (such as a mere roughness of the endocardium), may, as I have stated above, cause a murmur without producing any interference with the circulation; (*b*) there may have been no time for such alterations to have been produced, as, for example, in recent endocarditis. Again, the dynamic murmurs which occur in profound anæmia may be associated with symptoms such as occur in organic lesions, dropsy, shortness of breath on exertion, &c.

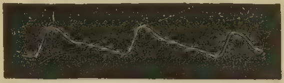
3. *The point of maximum intensity of the murmur.*—Inorganic murmurs are most frequently heard in the pulmonary area in the second left interspace, at a point an inch and a half to the left of the sternum, less frequently over the aortic area, and more rarely over the mitral area.

4. *The extent of propagation.*—Inorganic murmurs are not, as a rule, well propagated; an aortic murmur which is propagated into the vessels of the neck, and a mitral murmur which is heard at the inferior angle of the left scapula, are probably organic.

5. *The effect of treatment* is most valuable in a diagnostic point of view[3] (for in cases of simple anæmia, chlorosis, for example, the murmur speedily disappears).

6. *The character of the sphygmographic tracing* may be of value, more especially in deciding whether an aortic systolic murmur is organic or functional. The accompanying tracing (Fig. 17) was taken from a case which was admitted to the Newcastle-on-Tyne Infirmary under my care some years ago. The patient, a male, was markedly anæmic; there was a well-marked systolic aortic murmur; the left ventricle was not markedly hypertrophied. The tracing seems to show that, in addition to the anæmia, there was some constriction of the aortic orifice.

FIG. 17.



Aortic Stenosis.—J. B——, aged fifty-one. Admitted to Newcastle Infirmary, under Dr. Byrom Branwell, Nov. 29th, 1878, suffering from anæmia and dropsy. There was a well-marked aortic systolic murmur; the left ventricle was not hypertrophied. The pulse-tracing seems to show that the murmur was organic, and not hæmic. Pressure 1½ oz.

7. *The sound characters of the murmur.*—Inorganic murmurs are generally soft and of short duration. Organic murmurs may also be soft and feeble, but in such cases the lesion is often serious, and there are marked symptoms of cardiac failure.

The murmur is organic. What is the extent of the lesion; and what is its gravity?—In recent cases it may be impossible to decide these points. In chronic cases, the following circumstances must be taken into consideration in estimating the extent of the lesion:—

1. *The effect of the lesion on the heart and circulation.*—It may be stated as a general proposition that the great effect of all valvular lesions is to prevent the steady onward passage of the blood-current. Obstructive lesions (stenosis) produce this effect *directly* by preventing the passage of the usual quantity of blood from those parts of the circulation which are situated behind the narrowed orifice (from the right auricle and parts behind it in the case of mitral stenosis; from the left ventricle and parts behind it in aortic stenosis). Regurgitant lesions produce this effect *indirectly* by allowing some of the blood which should be passed forwards to flow backwards through the incompetent orifice (from the aorta to the left ventricle in aortic regurgitation, from the left ventricle to the left auricle in mitral regurgitation).

In seeking therefore to estimate the extent of any valvular lesion, it is necessary to examine the effects produced:

(*A*) *Behind the lesion*, in the cavities of the heart and in the circulation behind the affected valve, more especially therefore the extent of venous obstruction.

---

[1] In the case of organic murmurs there is no (permanent) structural alteration of the valve itself to account for the murmur. Inorganic murmurs are due either to altered conditions of the blood itself (hæmic murmurs) or to temporary alterations in the ventricular cavities (such as dilatation), spasm of the musculi papillares, permitting temporary regurgitation. The so-called dynamic murmurs are in reality therefore organic murmurs of temporary duration. The so-called hæmic murmurs depending upon clots in the heart cavities I regard as organic, and class accordingly. Inorganic murmurs are very common in conditions of anæmia. They are always systolic, and are most frequently heard in the pulmonary area (in the second left interspace at a point an inch and a half outside, to the left, of the sternum).

[2] Naunyn, George Balfour, and others deny that the inorganic murmurs of chlorosis are ever arterial, and say that they are due to mitral regurgitation. The arguments for and against this view were stated in a former lecture.

[3] This statement does not apply to cases of progressive pernicious anæmia—the anæmia of leucocythæmia and some other affections in which treatment is frequently useless.

(*B*) *In front of the lesion*, more especially the condition of the arterial circulation.

The more extensive the lesion the more extensive and more manifest are these effects.—This is true as a general proposition, but, as we shall presently see, the nutritive condition of the tissues (the tendency to withstand or to undergo degenerative changes) is a very important factor in the production of symptoms.

I will now briefly describe the chief effects of the different valvular lesions on the heart and circulation.

1. MITRAL STENOSIS.

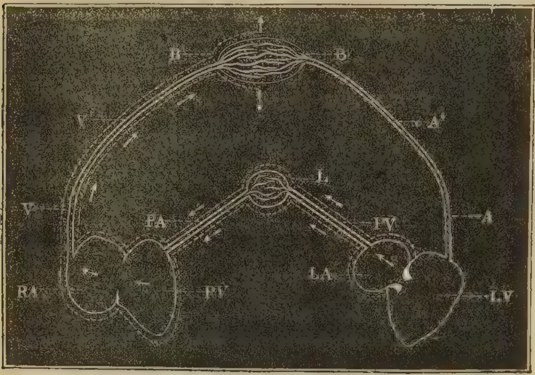
A. Backward effects.

(*a*) The right auricle is over-filled with blood and becomes hypertrophied and dilated. This increase in size must be looked for by percussion.

(*b*) The pulmonary veins become engorged.

(*c*) The lungs become congested: *lung symptoms* consisting of shortness of breath, especially on exertion, going upstairs or up a hill; tendency to catarrhal affections of the lungs and bronchi, especially chronic bronchitis; œdema of the lungs; hæmoptysis from engorgement or pulmonary apoplexy; effusion into the pleural cavities (hydrothorax), &c.

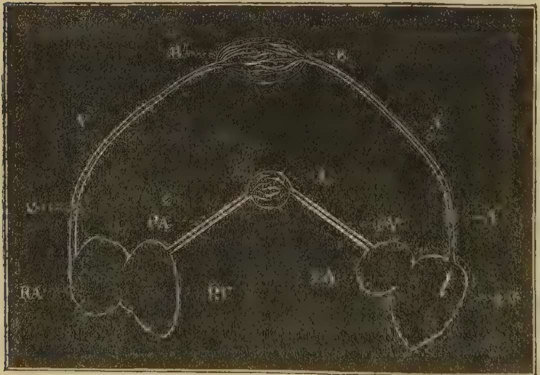
FIG. 18.



Graphic representation of the effects of a lesion of the mitral valve (mitral stenosis in this case) on the heart and circulation. The effects of mitral regurgitation are the same, but there is, in addition, hypertrophy of the left ventricle. LV=left ventricle; LA=left auricle; PV=pulmonary veins; L=lungs; PA=pulmonary artery; RV=right ventricle; RA=right auricle; V=venæ cavæ; V¹=venous system; B¹=termination of the venous system in the systemic capillaries; A=the aorta; A¹=the arterial system. The arrows show the direction of the backward pressure. The dotted lines show the effects of the obstruction (dilatation) on the different parts.

(*d*) The pulmonary artery becomes engorged, the tension of the blood which it contains is increased; the pulmonary valves are consequently closed with increased force, and *the pulmonary second sound is accentuated* and is louder than the aortic. The aortic second sound is less loud than in health, because of the small amount of blood passing from the left ventricle to the aorta. The accentuation, therefore, of the pulmonary second sound is in part then only apparent.

FIG. 19.

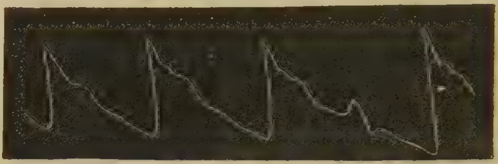


Graphic representation of the effects of a lesion of the aortic valves (aortic regurgitation in this case) on the heart and circulation. The letters have the same significance as in Fig. 18. The left ventricle is hypertrophied and dilated; the mitral valve is as yet competent.

The amount of accentuation is, as Skoda was the first to point out, a gauge of the extent of the mitral lesion. *Comparative auscultation of the aortic and pulmonary second sounds should therefore be made.*

The second cardiac sound is frequently reduplicated, owing probably to delayed closure of the pulmonary segments. The right ventricle has difficulty in emptying itself, and its contraction occupies more time than that of the left; hence the pulmonary segments are closed a little later than the aortic.

FIG. 20.



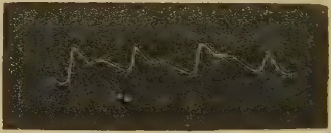
Irregularity of the Pulse.—W. M——, aged fifty, admitted to Newcastle Infirmary under Dr. Byrom Bramwell, Nov. 30th, 1878, suffering from the usual symptoms of mitral disease. The heart's action was extremely irregular. The left ventricle much hypertrophied. There was no rheumatic history. The symptoms were of two months' duration. Pressure 3¾ oz.

(*e*) The right ventricle becomes engorged, hypertrophied and subsequently dilated. *The increased size of the right heart is to be ascertained by percussion.*

(*f*) The right auricle becomes engorged, hypertrophied, and dilated.

The tricuspid valve ultimately gives way and becomes relatively incompetent. When this occurs, a systolic tricuspid murmur and venous pulsation in the neck (right external jugulars) are present.

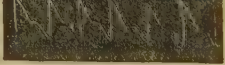
FIG. 21.



Small Pulse of Mitral Regurgitation.—H. M——, aged seven, admitted to the Newcastle Infirmary, under Dr. Byrom Bramwell, Oct. 16th, 1878, suffering from mitral regurgitation and severe bronchitis. There was considerable hypertrophy of the left ventricle. The tracing was made when the patient was convalescent from the bronchitis. Pressure 1½ oz.

(*g*) The systemic venous circulation becomes engorged.[4] The face, more especially the lips, becomes blue and slightly swollen. Dropsy commences in the feet, and gradually extends upwards, finally affecting the peritoneum and other serous cavities. Cardiac dropsy is most marked at night, and is frequently absent in the morning. It commences in the feet because the circulation is there slowest, the feet being the parts of the body most distant from the heart, and because the return current from the feet has, when the patient is in the erect position, to overcome the force of gravity.

FIG. 22.



Mitral Regurgitation.—M. A. C——, aged sixteen, admitted to Newcastle Infirmary, under Dr. Byrom Bramwell, Jan. 24th, 1878, suffering from cough and shortness of breath, dating from an attack of rheumatic fever two months previously. Heart's action very rapid (120-130). The first sound appeared to be reduplicated; a systolic murmur at the apex, audible when the heart became slower. Pressure 3 oz.

Engorgement of the stomach, with resulting chronic catarrh, foul tongue, &c.

Engorgement of the liver, enlargement of that organ, slight jaundice, possibly towards the end of the case, hepatic venous pulsation.

---

[4] This, of course, occurs before the tricuspid incompetence mentioned above.

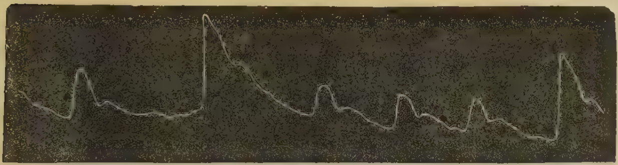
Engorgement of the kidneys, scanty urine containing abundant urates, albumen, but no casts.[5]

Engorgement of the brain with mental cloudiness, tendency to sleep, &c.

I have attempted to represent graphically the backward effects of mitral and aortic lesions in Figs. 18 and 19.

B. Forward effects.—Small and variable quantities of blood are passed into the left ventricle through the stenosed orifice. Small and variable quantities of blood are consequently pumped into the arterial system, the pulse is therefore small, unequal in volume, and irregular in time. The sphygmographic characters of the pulse are not very distinctive. Mahomed thinks the occurrence of a second small imperfect contraction may be peculiar. (See Fig. 20.)

FIG. 23.



Mitral Regurgitation.—S. B——, aged fifty-eight, admitted to the Newcastle Infirmary, under Dr. Byrom Bramwell, Feb. 25th, 1878, suffering from cardiac dropsy. There was a well-marked mitral systolic murmur, which disappeared under treatment. The heart was considerably enlarged (hypertrophied and dilated). Pressure 4 oz.

The contraction of the left ventricle is less powerful than in health, and the first sound, as heard over the left heart, is modified in the manner already described. The left ventricle is not increased in size; in fact, in some cases it is smaller than in health.

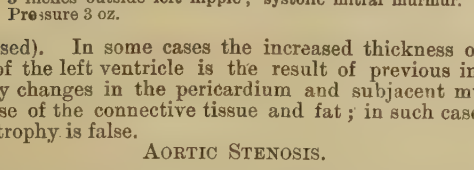
MITRAL REGURGITATION.

A. Backward effects.—The same as in mitral stenosis. (See previous page.)

B. Forward effects.—The pulse is small and irregular, but not so unequal in volume as in mitral stenosis. The sphygmographic characters are seen in Figs. 21, 22, 23, 24.

The left ventricle is hypertrophied. The explanation of this is difficult. It is probably due to increased stimulation of the muscular wall of the left ventricle by the large quantity of blood which is poured into it from the left auricle (there is no obstruction at the mitral valve, and the tension of the blood in the left auricle and parts behind, is increased). In some cases the increased thickness of the wall of the left ventricle is the result of previous inflammatory changes in the pericardium and subjacent muscle, increase of the connective tissue and fat; in such cases the hypertrophy is false.

FIG. 24.



Irregular and Intermittent Pulse.—O. M——, aged forty, admitted to the Newcastle Infirmary, under Dr. Byrom Bramwell, suffering from cardiac dropsy. The heart was very much enlarged; apex-beat 4½ inches below and 3 inches outside left nipple; systolic mitral murmur. Pressure 3 oz.

AORTIC STENOSIS.

A. Backward effects.—The left ventricle becomes hypertrophied, in consequence of the increased effort required to force the blood through the stenosed orifice. So long as the mitral valve is sound, there are no *lung* or *venous symptoms* such as are seen in mitral lesions. (See Fig. 19.)

B. Forward effects.—The pulse is small but regular, and of good tension. The sphygmographic characters are seen in Fig. 17.

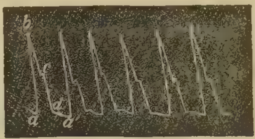
The smallness of the pulse and the amount of hypertrophy of the left ventricle are important indications of the amount of stenosis.

AORTIC REGURGITATION.

A. Backward effects.—The left ventricle becomes hypertrophied and dilated, the dilatation being partly due to the pressure which the regurgitant current exerts on the ventricular wall while in a condition of relaxation, partly to the impaired nutrition which results from interference with the coronary circulation.

So long as the mitral valve remains competent there are no lung or venous symptoms. Relative incompetence sooner or later results from the ventricular dilatation. Lung and venous symptoms are then superadded.

FIG. 25.



Aortic Regurgitation.—Case: G. A——, aged fifty-six, admitted to Newcastle Infirmary, under Dr. Byrom Bramwell, Feb. 21st, 1878, suffering from shortness of breath and swelling of feet. Had been ill for three months. The face was pale and anxious, lips slightly dusky. Double aortic murmur; heart considerably hypertrophied; apex between sixth and seventh ribs, 3 inches below and 2 inches outside left nipple. Considerable hypertrophy and engorgement of right heart. Died March 5th, 1878. Aorta very atheromatous; aortic valves very incompetent; segments shrunken, turned in towards the ventricle; coronary arteries much obstructed; cardiac walls fatty; left ventricle dilated; pericardium adherent. The arteries were practically empty during cardiac diastole. *a*—*b*=percussion-stroke; *b*=apex; *c*=tidal wave; *d* indicates the position of the aortic wave, which is absent in this tracing. Pressure 2½ oz.

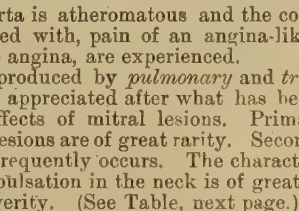
B. Forward effects.—The pulse is highly characteristic, presenting the well-known jerking, visible, collapsing, and tortuous character first described by Corrigan.

The sphygmographic characters of the pulse are seen in Figs. 25 and 26. The face is pale, and often wears an anxious expression. There is a tendency to syncope.

The amount of alteration of the pulse, the degree of hypertrophy and especially the degree of dilatation of the left ventricle, and the condition of the mitral, are the points to which attention should be particularly directed in the examination of a case of aortic regurgitation.

In many cases of aortic regurgitation, especially where the base of the aorta is atheromatous and the coronary circulation is interfered with, pain of an angina-like character, or attacks of true angina, are experienced.

FIG. 26.



Aortic Regurgitation.—Taken from same patient as No. 25 after administration of digitalis. The letters have the same significance as in Fig. 25. Pressure 3 oz.

The effects produced by *pulmonary* and *tricuspid* lesions will be readily appreciated after what has been said in describing the effects of mitral lesions. Primary pulmonary and tricuspid lesions are of great rarity. Secondary tricuspid regurgitation frequently occurs. The character and amount of the venous pulsation in the neck is of great importance in gauging its severity. (See Table, next page.)

The gravity of the lesion depends upon—1. *The extent to which the lesion can be compensated.*—In all cases of valvular lesion there is an attempt made by nature to meet the difficulty. The hypertrophy of the left ventricle which follows stenosis of the aortic orifice is the best example of this fact.

In many cases the balance between the lesion on the one hand and the compensatory changes in the heart on the other is so even that little or no disturbance of the circulation, and hence no symptoms result. The extent, therefore, to which the lesion can be compensated, and the length of

---

[5] A few hyaline casts are sometimes seen. Other forms of casts may, of course, be present as the result of secondary changes in the kidney, or of intercurrent inflammatory attacks.

TABULAR STATEMENT SHOWING THE POINTS OF DIFFERENTIAL DIAGNOSIS OF CARDIAC VALVULAR LESIONS.

	CHARACTERS OF THE MURMUR.			EFFECTS OF THE LESION ON THE HEART AND CIRCULATION.								
Lesion.	Point of differential maximum intensity.	Rhythm.	Directions of propagation.	Left ventricle.	Left auricle.	Lungs.	Pulmonary second sound.	Right ventricle.	Tricuspid valve.	Right auricle.	Systemic venous circulation.	Arterial circulation; pulse.
Mitral stenosis.	Apex, which is normal.	Presystolic.	Downwards and inwards, to a limited extent.	Normal or small.	Dilated and hypertrophied.	Engorged lung symptoms.	Accentuated.	Hypertrophied and dilated.	Towards end may be incompetent.	Dilated and hypertrophied.	Engorged; dropsy; face blue, and effects of engorgement of stomach, liver, kidneys, brain, &c.	Small, weak, unequal in volume, irregular in time.
Mitral regurgitation.	Apex, which is displaced downwards and outwards.	Systolic.	Upwards and outwards to left axilla, and inferior angle of left scapula.	Hypertrophied and dilated.	Dilated and hypertrophied.	Engorged lung symptoms.	Accentuated.	Hypertrophied and dilated.	Towards end may be incompetent.	Dilated and hypertrophied.	Engorged; dropsy; face blue, and effects of engorgement of stomach, liver, kidneys, brain, &c.	Small, weak, and irregular in time.
Aortic stenosis.	Second right costal cartilage.	Systolic.	Upwards along course of aorta, and into vessels of neck.	Hypertrophied.	Normal.	Normal.	Normal.	Normal.	Normal.	Normal.	Normal.	Small, regular, and of good strength.
Aortic regurgitation.	Second right costal cartilage, mid. sternum, lower end of sternum.	Diastolic.	Downwards to lower end of sternum.	Hypertrophied and dilated.	Normal so long as mitral valve is sound.	Normal so long as mitral valve is sound.	Normal so long as mitral valve is sound.	Normal so long as mitral valve is sound.	Normal so long as mitral valve is sound.	Normal so long as mitral valve is sound.	Normal so long as mitral valve is sound; face pale.	Jerking, visible, collapsing, and tortuous.
Tricuspid regurgitation (usually secondary).	Lower end of sternum.	Systolic.	Upwards and outwards towards right.	Normal if lesion is primary.	Normal if lesion is primary.	Normal or anæmic if lesion is primary.	Weak if lesion is primary.	Hypertrophied and dilated.	Incompetent.	Dilated.	Engorged; venous pulsation in neck; dropsy, &c.	Small, weak, irregular.

time which this compensation can be maintained, are most important points in estimating its gravity.

The extent of compensation depends upon:

(*a*) *The general reparative power of the individual.*—A valvular lesion of moderate extent occurring in an individual whose tissues are prone to degeneration or already in a state of decay is much more serious than a lesion of far greater extent in a healthy person.

(*b*) *The special reparative power* (*conditions of nutrition*) *of the cardiac muscle.*—So long as the cardiac muscle remains sound (the hypertrophy good), compensation is maintained and symptoms are at a minimum. Wherever degeneration of the cardiac muscle and consequent dilatation occur compensation fails and serious symptoms result.

The structural soundness, therefore, of the cardiac muscle (the presence or absence of dilatation) is of the utmost importance in a prognostic point of view.

2. *The extent of the lesion.*—Other things being equal, the more extensive the lesion the more serious the case.

3. *The nature of the lesion.*—Clinical experience tells us that some valvular lesions are more serious than others. Walshe gives the following as the order of relative gravity, estimating the gravity not only by the ultimate lethal tendency of the different lesions, but by the amount of complicated miseries which they inflict.

1. Tricuspid regurgitation (most grave).
2. Mitral regurgitation.
3. Mitral constriction.
4. Aortic regurgitation.
5. Pulmonary constriction.
6. Aortic constriction (least grave).

The relative gravity as regards tendency to sudden (instantaneous) death is, however, quite different. *Aortic regurgitation* frequently proves suddenly fatal by syncope. The other valvular lesions do not cause sudden death.

4. *The surroundings and habits of the patient.*—Valvular lesions, other things, such as the condition of tissues, &c., being equal, are much less serious in persons in comfortable circumstances than in those who struggle for existence, and have to lead laborious lives. Indeed, rest to the damaged organ is the first and most important indication for treatment.

5. *The mental temperament of the patient* is, for the same reason, of some importance. Valvular lesions are less serious in persons of a quiet and placid disposition than in persons of an excitable and anxious temperament.

6. *The age of the patient* is of some value, as it gives a general idea of the qualitative state of the tissues.

In young subjects compensation is much more active than in old people. This is not, perhaps, an unmixed evil; it would almost seem that in some cases of valvular lesion running a rapid course in young subjects, that the lesion grew *pari passu* with the general bulk.

7. *The etiology of the lesion.*—Valvular lesions of rheumatic origin are, as a rule, less serious than those which result from other causes, probably because the average age of rheumatic cases is younger than that of others, and hence the reparative process and compensation are more perfect. Non-rheumatic valvular lesions are often due to degenerative processes. In such cases repair and compensation are slight, and there are often complications, such as structural kidney lesions and the like.

Acute valvular lesions occurring in the course of pyæmia, scurvy, and other blood diseases (ulcerative endocarditis) almost invariably give rise to speedy death.

8. *The associated pathological conditions* are of great importance. In fat, flabby individuals, and in all cases in which the tissues are prone to degenerate, the prognosis is bad. Kidney disease and other complications, of course, render the case more serious.

9. *The duration of the case and the effects which the lesion has already produced* are of great value. The shorter the duration and the greater the effects, the worse the prognosis.

In speaking of the prognosis I have said nothing with regard to the sound character of the murmur. The mere loudness of a murmur is no criterion of the gravity of the lesion. The loudness of a murmur depends in great part upon the force of the blood-current which produces it. Where the heart is feeble or the walls degenerated, the murmur is less loud than where the cardiac muscular tissue is sound. Hence feeble murmurs are frequently more serious than loud ones, and indeed in some of the worst cases of valvular disease, as, for example, in extreme mitral stenosis, there may be no murmur at all.

ABSTRACT OF

The Brown Lectures.

FURTHER INVESTIGATIONS ON ANTHRAX AND ALLIED DISEASES IN MAN AND ANIMALS.

BY PROF. W. S. GREENFIELD, M.D., F.R.C.P.

LECTURE III.

ANTHRAX IN MAN.

ANTHRAX may affect the human subject in at least three different ways—malignant pustule, anthrax œdema, and internal anthrax. *Malignant pustule* occurs almost invariably as a primary lesion following direct inoculation. It is usually seated on the face, neck, or hand, or some exposed part of the body, and commences by a small red point or pimple, which may be painless, or attended by a sensation like that of the sting of an insect. A small papule speedily forms, which becomes covered by a flat vesicle, which enlarges and usually bursts, discharging a clear or bloody fluid. A central black eschar forms at the base of the discharged vesicle, and other smaller vesicles form around it. The surrounding tissues become inflamed, so that the vesicle is seated on a hard red base, with a sort of erysipelatous blush and swelling extending a considerable distance around. The central eschar enlarges, and the corona of vesicles, as well as the inflammatory sore and œdema, increase to such an extent that when seated on the face, the entire side of the face, head, and neck may be involved in the œdematous swelling. There is often enlargement of the corresponding lymphatic glands. If the patient survive the central slough separates, the wound granulates, and the œdema and lymphangitis subside. The constitutional symptoms vary very greatly. They may be slight or wanting, even when the local condition is most typical, or there may be slight depression and some febrile symptoms. Far more commonly there is marked fever, the temperature rising as high as 106° F. or more, and there are severe constitutional symptoms, either shivering, vomiting, accelerated pulse and respiration, great prostration and anxiety, delirium, and rapid death, sometimes in convulsions, or great depression and prostration, sleeplessness, laboured breathing, profuse perspirations and other symptoms of fever with exhaustion, ending sometimes in delirium. Death may occur in thirty or forty hours from the formation of the pustule, or the patient may die at the end of four, five, or six days, not often later. The following cases may be cited as illustrative of the disease:—

CASE 1. (Communicated by Dr. Bell of Bradford.)—J. G——, aged thirty-six, a woolsorter, in good health, had been sorting Persian wool till June 9th, and from that time to June 19th Bokhara wool, noticed a small pimple on the anterior and outer surface of the arm over the elbow-joint on June 15th. On the 18th it was inflamed and painful, but he continued at work. On the 21st there was a bulla an inch in length and three-quarters of an inch in breadth, with a dark-coloured base and filled with serum; the skin and tissues for an inch around were hard, and the inflammation extended to the upper third of the arm and lower third of the forearm and two-thirds around. He did not feel ill; his appetite was moderate; he slept well; pulse 68. For a few days the vesication extended at the margin of the sore, but on June 28th the slough was detaching, and the man completely recovered. There was not apparently any enlargement of the axillary glands. Blood taken from the brawny swelling around the sore contained scarcely any bacilli, but a few typical bacilli were found in the serum from the vesicles around the slough on June 23rd, and on inoculation of a guinea-pig with a very minute quantity, death ensued in twenty-nine hours, and its spleen, which was greatly swollen, soft, and vascular, swarmed with bacilli when examined an hour after death, so that in a very mild case as regards general symptoms the poison was present in the most virulent form.

CASE 2.—W. E——, a boy, aged fifteen, employed in the yard of a factory where Van mohair was largely used, went one day into the room where his brothers were sorting this wool, and whilst playing with them they pushed him into the wool head foremost. This was on June 23rd. At that time he had a small pimple over the outer angle of the left malar bone. On the 25th a change was observed in the pimple, but no special notice was taken of it. On the 29th, when he got up, the eyelid and side of the face were swollen, and in the afternoon he felt so poorly that he had to come home from work. He was not, however, seen by Dr. Logan until the evening of July 1st, when the whole side of the face and neck were swollen, and in place of the pimple was a vesicular ring, with a bulla in the middle which had burst, having a dark depression in the centre. Temperature 105°; pulse rapid and weak, and he was delirious. Later there formed the usual black eschar, which reached the size of a florin. He was very ill for four or five days. Dr. Greenfield saw him on July 10th. He was then able to walk, but still very weak. There was a very typical black eschar the size of a shilling, surrounded by a narrow ring of vesicles and a still swollen indurated base. The swelling of the face continued, and there was very great engorgement of the lymphatic glands of the neck and the supra-clavicular region of the same side. Blood taken from the margin of the swelling on July 6th was without effect on inoculation.

CASE 3.—A man, aged sixty-three, the minder of a preparing box, the machine through which the wool is passed after it has been sorted. He noticed on Aug. 28th that his lower lip was swollen, and that a pimple which he had had for about a week below the lip was inflamed and painful. On the 29th he was up and in bed repeatedly; did not feel well; vomited once. Next day the swelling increased, and in the evening of the 31st he sent for the doctor, who found a vesicle, with an inflamed hæmorrhagic base about the size of a sixpence; this burst, leaving a dry gangrenous-looking centre surrounded by a ring of vesicles, the whole being on a very inflamed base. There was great surrounding swelling, and the submaxillary lymphatic glands were much swollen. Considerable improvement occurred the next two days, but on the night of Sept. 3rd he became delirious, and at 10 A.M. on the 4th he was comatose—temperature 103°, pulse 140, respiration 33—and died at 2 P.M. The serous fluid taken from the vesicles on the lip, and the blood from the surrounding swelling on the day of death, contained typical anthrax bacilli.

Internal anthrax.—It has been known for some time that there are cases of rapidly fatal disease by means of an internal inoculation. In 1872 Wagner published such a case, which he called "mycosis intestinalis," and two years later he wrote a paper entitled "Intestinal Mycoses, and their Relation with Splenic Fever," in which he recorded eight cases, where, in addition to the gastro-intestinal lesions, there was bacillus anthracis in the blood. In its general character and mode of onset this "intestinal mycosis" resembles in some respects the form shortly to be described of internal anthrax or anthracæmia. But other symptoms appear early, as vomiting, sometimes dysphagia, slight pain and uneasiness in the abdomen, colic, or diarrhœa. The diarrhœa may be bloody from the first. There is great prostration, cyanosis, and collapse, often without elevation of temperature. Death may occur in twenty-four hours, or be delayed two or three days. Post-mortem: There is often some blood-stained serum in the peritoneal cavity; the mesenteric and retroperitoneal glands are infiltrated with semi-gelatinous fluid; the walls of the stomach and parts of the intestine are swollen and congested, with submucous hæmorhages sometimes. The enteric mucous membrane may be injected or merely stained with blood. The intestinal canal contains blood-stained mucous or watery blood-stained fluid. Rarely there occur pustular or carbuncular foci in the intestines. In addition to these special local conditions there may be one or more of the conditions met with in the general and pulmonary forms. Other observations on supposed internal anthrax, by Huber and Butler, Leydig and others, were next referred to.

The observations of Frisch upon rag-disease (Hadern-krankheit) were then briefly described; they are not at all conclusive, but rather against the view that this disease is anthrax in any form. The mode of death of the dog inoculated with blood taken from subjects of the disease differed from that of anthrax, and the organisms found in the dog's blood were not bacilli but spores. Rabbits experimented on died much more rapidly than in anthrax, and all points to the affection being a peculiar form of septicæmia. Very similar effects were obtained by Dr. Greenfield in some experiments, narrated in his lectures last year, of inoculation with putrid blood, which had been kept for several weeks, taken from horses which had died of supposed anthrax at the Cape.

In the report of the medical officer of health for Glasgow, Dr. James B. Russell (Report of the Medical Officer of the Local Government Board, 1878), a number of cases of malignant pustule occurring amongst hair-spinners working in Russian horsehair were narrated, and reference is made to cases of fatal illness amongst workers in the same factory, which he believes must have been due to the same cause, although without external pustule. But there do not appear to be any satisfactory records of cases of disease of the form under consideration, and therefore it may be well to give an outline of the facts recently revealed by the investigation of so-called "woolsorters' disease" at Bradford, especially as their connexion with anthrax has been conclusively established.

A number of cases of death had occurred amongst workmen employed in wool-factories in Bradford and its vicinity, especially amongst those engaged in sorting and preparing in the raw state certain kinds of mohair. It had been observed that these cases were almost entirely limited to these men, that they occurred in batches, that they had no special relation to age or previous health, and that they were attended by a peculiar train of symptoms, leading usually to rapid death, sometimes with pulmonary symptoms. Slighter ailments, sometimes even grave symptoms from which recovery ensued, and cases of malignant pustule and boils of various kinds, also occurred amongst the same class of workmen. The disease was so clearly associated in some way with the wool and hair that the working of it was regarded with dread; and at last, a number of cases occurring about the same time, the subject became manifestly one for inquiry. (This was undertaken for the Local Government Board by Mr. John Spear in association with Dr. Greenfield.) It is to the untiring industry and devotion, the steady pertinacity, combined with the scientific acumen of a member of our profession—Dr. Bell of Bradford—that the credit both of working out the history of the disease and first suspecting its cause is unquestionably mainly due.

Dr. Greenfield then gave an account of the origin of the kind of wool which is most infectious—the Van or Persian mohair; the most deadly being that which is classed as inferior, and contains together with much dirt many so-called "fallen fleeces"—i.e., the fleeces of animals dying a natural death. It is the sorting of this wool—a process which leads to the disturbance of a quantity of dust—that is so dangerous. The wool waste, the dust which collects from the sorting, is almost invariably used as manure; and the water employed in washing is sometimes passed into the sewers, whence it may be distributed over sewage farms. Instances of splenic fever in cows and sheep on pastures so irrigated were related in the first lecture.

The clinical records of woolsorters' disease permits of its division into three classes—one in which the symptoms are fulminant, intense, and rapidly fatal; another in which though severe, the fatal issue is delayed three, four, or five days; and a third in which the disease extends over a week, and is fatal, if at all, from secondary complications. The symptoms of the more rapid form are well illustrated by a case which has been recorded by Dr. Bell in THE LANCET of June 5th, 1880. This was a case of a man, fifty-eight years of age, previously in perfect health. On June 28th, 1877, he said on reaching home that he had opened a bad bag, and had some very nasty and offensive work. He slept well through the night, was up early next morning, had breakfast, and said nothing about feeling unwell. He perspired much at his work, and at 10 A.M., feeling very unwell, had to leave. He had great difficulty in walking home—two miles and a half—was much exhausted, and went to bed, oppression of breathing being especially noticed. He was seen at 7 P.M., was then perspiring freely; there had been no shivering or chilliness, no vomiting, thirst, or pain. There was some wheezing in the trachea; very little cough; no expectoration; respiration 34; expiration prolonged; no dulness on percussion; some rhonchus over right base, but no moist sounds; axillary temperature subnormal; rectal 102·2°. At 11.30 P.M. aspect anxious, face pale, with slightly leaden hue. He said he felt very poorly, but had no pain; respiration became more laboured; pulse rapid and irregular; and he died three hours afterwards. Such intensely rapid cases as these, though probably not uncommon, have not recently come under observation, but cases having these clinical features are not uncommon in some other centres of wool or hair manufactories. More frequently the symptoms resemble those of other forms of blood-poisoning. The onset is often sudden, sometimes gradual, and preceded by malaise for some days, with all the various general premonitory symptoms which are apt to usher in other acute febrile and septic diseases.

Of the declared symptoms, the earliest are usually great prostration and a sense of oppression of breathing. Distinct shivering or rigor appears to be rare, initial vomiting is not frequent. There may be headache, nausea, but this may be absent and appetite be good. An emotional condition and occasionally a sort of hysterical state may be shown early in the case. It often happens that the patient is so unconscious of any danger, that he refuses to send for a doctor until within two or three hours of death, and in several recorded cases has attempted to go to work, or even done so, within five or six hours of death. The respiratory symptoms are generally well-marked at an early stage. The breathing is laboured and difficult, not usually much accelerated, and often with a sense of pressure or constriction. There may be only slight blood-stained expectoration, or this may be profuse, or, on the other hand, absent. Nothing beyond slight rhonchus is to be made out on physical examination. The pulse is usually rapid and weak, occasionally irregular. The face is sometimes congested, more commonly pale, with a slight cyanotic tint. The extremities are cold and bluish, and the temperature of the surface of the body subnormal. The rectal temperature is usually two or three degrees higher than the axillary, or there may be even greater difference. Profuse and repeated perspirations are not uncommon. The appetite may be good and digestion also apparently good, but vomiting is not uncommon, and it may be repeated and urgent, and not related to food. Diarrhœa is occasional, not constant or bloody. The mental condition varies: anxiety and depression are the rule in the early stages; later the mind may be clear to the last, or delirium may set in some time before death. Convulsions are not uncommon at the stage of collapse, a comatose condition being present in the intervals of the convulsions. As the case progresses the dyspnœa becomes more intense, and death sometimes occurs quite suddenly, as if from syncope or collapse. When more prolonged there are abundant rhonchi and mucous râles over the entire chest, especially posteriorly, and percussion dulness at the bases may be found. Occasionally tetanic spasms or coma lead to the fatal issue. The rectal temperature is seldom higher than 102° or 103°, and in some cases has been normal or subnormal. A higher temperature is frequently present in cases of external malignant pustule, and also in some of the cases diagnosed as woolsorters' disease, and generally in the most favourable cases. There may be a secondary pneumonia, attended by the usual symptoms, and fatal at a later period.

The post-mortem appearances vary considerably; the differences observed appear to depend partly upon the duration of the disease and partly upon the point of entrance of the poison into the system. No cases resembling "intestinal mycosis" have been observed in the cases of woolsorters' disease that have been investigated. In the more rapidly fatal cases the lesions resemble much those found in ordinary bovine splenic apoplexy, or in the lower animals inoculated with the intensest virus. There is usually a marked cyanotic appearance, and decomposition is said to be somewhat rapid. There is no external swelling, no petechiæ, no swelling of throat or neck. The lung tissue may be congested or quite natural; there may be ecchymoses beneath the bronchial mucous membrane and in the pericardium. The abdominal viscera show no change, except slight cloudy swelling of the kidneys and liver. There may be hæmorrhages in the lungs, heart, kidneys, and other organs. These cases are much rarer than those in which there is cellulitis in the neck, especially around the pharynx, and more often blood-stained serous or gelatinous infiltration of the mediastinal tissues. The bronchial glands are swollen, softened, and congested, with more or less hæmorrhage into or around them. The tissues at the root of the lung may be similarly infiltrated, and there may be from one to two pints of fluid in the pleuræ, with consequent partial collapse of the lungs. There may be blood-stained secretion in the bronchi, yellowish or blood-stained fluid in the pericardium, and ecchymoses in the visceral layer. There may be ecchymoses beneath the endocardium, and into the muscular tissue of the left ventricle; and blood-staining of the endocardium rapidly takes place. Sometimes submucous ecchymoses in the pharynx, and slight in the stomach, but nothing in the intestinal tract. The spleen is hardly, if at all, changed, the extremely vascular and almost diffluent condition observed in animals not being met with. Nothing noteworthy in the liver; but the kidneys are often swollen and the seat of ecchymoses. Rarely there is serous infiltration beneath the peritoneum, or less commonly along the retro-peritoneal glands. Brain is usually healthy, less frequently there are ecchymoses in the pia mater, or extensive hæmorrhages. Rarer conditions are large hæmorrhages in front of the pericardium and into the mediastinum, or around the pharynx, with swelling of the cervical glands. The rarer conditions met with in prolonged cases consist in hæmorrhagic infarctions in the lungs, sometimes accompanied by superficial pleurisy; or less often patches of broncho-pneumonic consolidation, sometimes with softening or suppuration. This condition must be regarded as due not merely to prolonged congestion, but to the presence of blood-poisoning, or possibly some predisposition. They may occur in cases in which the history points to the anthracial origin, and in which also bacilli are found in some of the fluids.

Dr. Greenfield next proceeded to detail the evidence upon which the foregoing observations were based. He showed that the whole subject of anthrax is in a transitional state, that the criteria for its diagnosis hitherto accepted are obviously inadequate, and that in order to insure proper attention to the prevalence of the disease and the modes of its diffusion, every possible objection and difficulty must be met, however trivial.

GROUP A. *Cases in which no definite result was gained by inoculation.*

These cases were also first in chronological order.

CASE 1.—That of a man employed for some weeks in sorting Van mohair until Saturday May 1st. At 7 P.M. on that day he complained of feeling sick, coldness, and oppression at the chest. On Sunday he stayed in bed. On Monday he had frequent vomiting, and from that time till death had repeated attacks of coldness and profuse perspiration, with increasing cyanosis. The mind was clear to within one hour and a half of death, when convulsions set in and lasted an hour. He died at 8 P.M. on May 5th, the entire duration of the attack being four days and of the definite symptoms two days. The post-mortem revealed much serous effusion in both pleuræ, without any signs of inflammation; pulmonary collapse; great enlargement of the bronchial glands, some of which contained blood-clot; some ecchymosis at base of heart and in valves; other organs natural. Blood taken from the body fifty hours after death and received after five days contained numerous motionless rods, many containing spores and other larger filaments; only a few ordinary bacteria. Inoculation with this fluid did not produce anthrax.

CASE 2.—A man, seventy-one years old, who had been washing wool, including Van mohair, till May 15th. On the morning of the 17th he felt unwell; on the 18th he had pain in the chest and abdomen, and felt cold. On the 19th there was vomiting, purging, great prostration, and some cyanosis; on the 20th increased cyanosis, great dyspnœa, and râles all over the chest, and he died early on the 21st. At the post-mortem examination, twenty-eight hours after death, there was marked decomposition and subcutaneous emphysema, and abundant gelatinous œdema in the mediastinal tissues, large quantities of fluid in the pleura, and œdema and some congestion of the lungs. The bronchial glands were greatly swollen and congested, blood-stained frothy mucus in the trachea and bronchi; also some injection of the peritoneum, swollen gelatinous œdema of mesentery, with swelling and congestion of the mesenteric and retro-peritoneal glands. Spleen enlarged, soft, and dark-coloured. Fluids from this case were received by Dr. Greenfield fifty hours after death. The blood from the spleen contained many rods, the larger ones blunt at the ends, and containing spores resembling those of bacillus anthracis. No bacterium termo. The pleural serum and fluid from the lungs contained very long rods containing spores. Inoculation with these fluids was without result.

CASE 3.—A woolsorter, thirty years of age, who had been sorting Cape mohair, was taken ill on May 18th, and died on May 27th, having had symptoms resembling those of subacute pneumonia. On post-mortem examination, twenty-three hours after death, pus was found encapsuled in the right pleural cavity; minute purulent spots, surrounded by congestion, scattered through both lungs; the bronchial glands swollen, softened, and infiltrated with blood; spleen enlarged, very soft; some hæmorrhage around one kidney; no bacilli found in the blood, only a few bacterium termo, but some bacilli in the pericardial serum and spleen; no result from inoculation experiments.

GROUP B. *Cases in which anthracoid nature was proved by the microscope and by inoculations.*

CASE 4.—A wool buyer, thirty-six years of age, who had not been known to be exposed to contagion from any of the ordinary wools; after about a week of malaise he left work on May 29th, and on the 30th was seized with illness, chiefly severe headache and dyspnœa. These continued and increased on the 31st and June 1st and 2nd, on the morning of which day the headache became more intense, and extended down the neck and back. He became unconscious and died at 4.30 A.M. on the 3rd after three days and a half illness. Post-mortem examination nine hours after death; numerous petechiæ on abdomen and chest; extensive hæmorrhages into the mediastinal tissues and epicardium, and some wedge-shaped hæmorrhages at the surfaces of the lungs. More than two pints of clear serum in each pleura. Hæmorrhage and inflammatory œdema around pharynx. Extensive extravasation of blood in pia mater. The fluids were received and examined thirty-six hours after death. No bacilli found in pleural or pericardial serum or in spleen; but in the blood a few very long bacilli. Inoculation successful, and practised on two heifers, one protected, the other not (see Lecture I.); and also of guinea-pig and mouse, producing most typical anthrax.

CASE 5.—A man employed in sorting inferior mohair which had been roughly washed. For four days before definite symptoms he had complained of feeling chilly and of aching in the limbs; but it was not till midday on July 22nd that he came home from work feeling thoroughly cold. Towards night he was very restless, with dyspnœa, profuse perspiration, and some cyanosis. He died next day at noon. An examination nine hours after death revealed extensive semi-gelatinous infiltration of the mediastinal tissues, large serous effusions in both pleuræ, and semi-gelatinous œdema of subpleural tissue. Bronchial glands swollen, soft, with ecchymosis in and around them. Small submucous hæmorrhages in the trachea and larger bronchi, which contained frothy blood-stained mucus. Blood received twenty hours after death contained a few typical anthrax bacilli; and inoculation of a guinea-pig produced death in thirty hours with typical anthrax. Similar results from blood from heart and spleen, and the juice expressed from a bronchial gland; and some very large bacilli in the pleural serum.

CASE 6.—That of a man thirty-nine years old, who had been sorting white Van mohair. On August 28th, feeling pain in his head, returned from work in the morning, but took a good dinner. Next morning he stayed in bed. There was some uneasiness in abdomen and free perspiration, and towards morning some dyspnœa. He got up next day to go to work, but the dyspnœa increased, together with a sense of prostration and coldness. At 9 A.M., respiration 46, pulse 120, very weak and intermittent; temperature 98°. Extremities cold and livid; profuse perspiration. Dulness at bases of lungs. He died at 2 P.M. of the same day.

Autopsy twenty-six hours after death.—The neck appeared swollen. There was emphysema of the areolar tissue in the anterior mediastinum, extending to the subperitoneal tissue of the abdominal wall; over pericardium some gelatinous exudation. Each pleura contained about four pints of serous fluid. Heart healthy; lungs collapsed but healthy. Bronchial glands greatly swollen, and the seat of extravasated blood. The fluids were examined forty-eight hours after death. In that from lungs were numerous bacilli in various stages of growth, and in the spleen, and guinea-pigs inoculated from each of these sources died in forty and sixty-six hours respectively, with greatly swollen spleen, containing abundant bacilli.

Thus out of eleven cases in all, either of malignant pustule or of supposed internal anthrax, six of which were fatal, experiments were made with nine, and in four only were any results obtained by inoculation of rodent animals. Yet in all the fatal cases microscopical examination revealed the presence of bacilli in one or more of the fluids or tissues of the body. The apparent discrepancy is explained when the length of time which elapsed between death and the inoculation experiments is considered; for when decomposition has already set in before the post-mortem is made, it is exceptional to produce results by inoculation with blood or other fluids. In all these cases in which the body was examined soon after death, the inoculation was successful, and hence it was in the later cases that these results were obtained.

SYPHILIS AND LOCOMOTOR ATAXY.

By W. R. GOWERS, M.D., F.R.C.P.,
ASSISTANT PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY COLLEGE;
PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED
AND EPILEPTIC.

MUCH attention has been lately directed to the existence of a causal relationship between syphilis and locomotor ataxy, and, in Germany especially, facts have been marshaled on each side of the discussion.

The occasional obtrusive association of the two diseases did not escape the keen eye of Duchenne, and his allusion to the subject, in his original papers on the disease, is worth quotation. "Some [ataxic] patients had suffered from constitutional syphilis; it was the only reasonable or apparent cause of the ataxy, but the causal relation is uncertain, for, apart from the special symptoms of syphilis, at its different periods, the locomotor ataxy presented, in these patients, no new or special symptoms, and specific treatment, as a criterion, was equally useless."[1]

No subsequent writer, with the exception of Schultze,[2] attached any importance to the association until in 1876 Fournier[3] insisted on its freqency. His experience that syphilis preceded ataxy in twenty-four out of thirty cases which had come under his notice was generally regarded as due to the special character of his practice. So also with an assertion of the frequent relationship of the two, made in this country by Drysdale. Vulpian, however, to whose sphere of observation the objection does not apply, stated in his lectures,[4] published in May, 1879, that "there are actually few patients with locomotor ataxy who have not had, some years before the appearance of the first symptoms of this affection, an infecting chancre and secondary syphilitic accidents. . . . . I do not think that it is an exaggeration to say that of twenty patients attacked with locomotor ataxy there are at least fifteen who are old syphilitic subjects." Attention has been specially drawn to the subject by a paper by Erb, published in July, 1879,[5] in which he stated that of forty-four cases observed consecutively, there was a history of antecedent syphilis in twenty-seven, or 61 per cent.

Statistics of a different character have been brought forward by German authorities, whose opinions are entitled to great weight. Westphal,[6] of seventy-five cases, found that 18½ per cent. had had primary sores only, and another 14½ per cent. had had secondary symptoms. E. Remak[7] found a history of syphilis in only one quarter of fifty-two cases, and Bernhardt[8] in the same proportion of thirty-seven cases.

The facts which have come under my own notice corroborate the statements of Fournier, Vulpian, and Erb. In 1878, in a paper read at the Bath meeting of the British Medical Association,[9] I expressed the opinion that syphilis must be regarded as a cause of locomotor ataxy in one-half of the cases of that disease; and I now propose to bring forward some evidence in support of this assertion. Thirty-three cases of the disease in men have come under my notice since I began to investigate carefully the relation to it of syphilis. My earlier notes include many instances in which syphilis preceded ataxy, but these have been rejected because in other cases observed at the same time the point was not noted. The thirty-three cases are thus unselected, the only cases rejected being some in which the ataxy was apparently secondary to an acute myelitis.

Of the thirty-three cases eighteen presented a clear history of constitutional syphilis, fifteen described both primary sore and secondary symptoms, three presented or described distinct secondary symptoms, although they were ignorant of having had a primary sore. Five other patients had had a sore, but no secondary symptoms could be ascertained. In the remaining ten cases there was no history of a sore or constitutional symptoms. One of these, however, had had a rash which he was sure was syphilitic, but he was told by a medical man that it was not. Of these ten patients five had suffered from gonorrhœa. Thus, of the whole thirty-three cases, twenty-three (about 70 per cent.) had suffered either from a primary sore or secondary symptoms, and in 53 per cent. there had been undoubted constitutional symptoms, of which in several the indications were still present.

The significance of these facts depends on the proportion of the male population of this country who have had primary sores or constitutional syphilis. Before assuming a causal relationship in these cases between the antecedent venereal disease and the subsequent locomotor ataxy we ought to deduct from the coincidences that proportion which the prevalence of venereal disease may have rendered accidental. Unfortunately, we have not the necessary information. But it is probable that the proportion of adult males, over twenty-five, who have had venereal sores or symptoms of constitutional syphilis is much smaller among the middle classes than among the poor. It is therefore of interest to inquire whether syphilis precedes ataxy with equal frequency in the two classes. Of the thirty-three cases twenty-one were seen in hospital practice, and twelve in private. Of the former there was a history of constitutional syphilis in ten, and of a venereal sore alone in five, making a total of two-thirds of the hospital cases. Of the twelve cases seen in private there was a history of secondary syphilis in eight, and of a venereal sore alone in one, a total of three-quarters of the cases. These facts suggest that syphilis is an antecedent of ataxy, at least as frequently in the well-to-do classes as among the poor.

If we deduct 20 per cent. as explicable by accidental coincidence, there will still remain 50 per cent. of the cases of ataxy in which we must regard the antecedent syphilis as the essential cause of the disease. It may not have been the only cause of the disease; sex, for instance, doubtless has an influence, but the teaching of these facts, as far as they go, is, that one-half of the patients with ataxy would not have this disease if they had not, at some previous period, suffered from syphilis.

How is this conclusion to be reconciled with the figures of Westphal, Bernhardt, and Remak? These facts were published soon after, and in contravention of the statements of Erb, and were manifestly based upon old notes of cases. Statistics so obtained are, it is well known, of very doubtful value upon many points, and, according to my own personal experience, upon this point for one. Erb himself affords an illustration of the change of opinion which may occur when attention is specially directed to a question. In his article in "Ziemssen's Cyclopædia" (written apparently in 1876), he said: "Among chronic diseases, syphilis has been often credited with being the cause of tabes, with what justice cannot as yet be determined. ...... Judging by my own experience this connexion seems doubtful."[10] His changed opinion in 1879 I have already stated.

In women it will probably be found that the proportion of cases presenting syphilitic antecedents is much smaller. Such is the experience of Erb and Westphal, and with it my own observation agrees, although my cases are too few to justify a confident statement.[11]

The lesion in locomotor ataxy is, however, very different from those which are ordinarily caused by syphilis. It is a degeneration limited to a system of structure, and contrasts with the random distribution of ordinary syphilitic processes. This objection has been urged with force by Broadbent, Julliard, Westphal, and others, and I can corroborate the statement of Westphal that in cases which succeed syphilis the lesion is precisely similar to that found in other cases. But theoretical considerations of this character must yield to facts. We know too little of any morbid agency thus to limit its possible operation to certain forms of effect, with which we happen to be familiar. Indeed, a study of the morbid changes which are universally admitted to be syphilis might make us hesitate in exclusions. In the falling off of the hair after syphilis we have a change which no one hesitates to ascribe to syphilis, but which is very unlike its other consequences, and might almost be described as a true degeneration of a system of structure."

[10] Ziemssen's Cyclopædia, American translation, vol. xiii. (1878), p. 528.

[11] Westphal's 75 cases included 20 women, in none of whom was there a history of syphilis. If these 20 cases are deducted, the proportion of the 55 men who had had secondary symptoms rises to 20, and a chancre only, to 25 per cent., making a total of 45 per cent.

The common failure of anti-syphilitic treatment in ataxic cases, which Duchenne pointed out, has been confirmed by most subsequent writers, with the exception of Fournier. It is, however, not altogether surprising, when we remember how different in character the lesion is from those which are commonly influenced by iodide and mercury. The failure of the therapeutic test cannot be held as invalidating other adequate evidence as to the causal relation of the two diseases. But although, as a rule, anti-syphilitic remedies have no marked influence on the disease, occasional exceptions are met with, and I have seen one case of early ataxy in which iodide and mercury effected a practical cure.

As a rule, the interval between the syphilis and the first symptom of the ataxy is considerable. It was noted by Erb in only 17 cases. In 5 it was between two and five years, in 8 between six and ten, in 4 between eleven and fourteen. In my own cases the exact interval was noted in 18 cases. The interval is, as a rule, longer than in Erb's cases. No case of simple tabes was met with earlier than seven years after infection, the actual numbers being: at seven years, 1; at nine, 3; at ten, 2; at thirteen, 3; at fourteen, 2; at fifteen, 1; at seventeen, 1; at twenty, 3; at twenty-one, 1; at twenty-five, 1. Thus two-thirds of the cases occurred more than ten years after the primary disease.

Some other degenerative diseases of the nervous system may be found to stand in a similar relation to syphilis. All Hutchinson's cases of "ophthalmoplegia externa,"[12] for instance, occurred after syphilis, although in the patient whose brain I examined the lesion was purely degenerative. Reflex iridoplegia, the loss of reflex action to light, with preservation of the associated action on accommodation, so common in ataxy, I have several times seen in syphilitic subjects without disease of the spinal cord, and Erb has described an example of the coincidence. Indeed, I believe that it may be taken as a practical rule that (apart from general paralysis of the insane) reflex iridoplegia always indicates either syphilis or tabes, and that it not unfrequently indicates both.

Other forms of degenerative disease of the spinal cord, which occasionally follow syphilis, may also have a causal relation to it. It seems that one effect of constitutional syphilis may be to induce a neuropathic state in which certain degenerative diseases of the nervous system readily occur.

Queen Anne-street, W.

CASE OF CEREBRAL ABSCESS.

BY EDWARD SEATON, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE GENERAL DISPENSARY, NOTTINGHAM.

ON Wednesday, Aug. 25th, 1880, I saw for the first time, in consultation with Dr. Massey, senior surgeon to the Dispensary, a boy named John B——, aged sixteen, the son of a groom residing in a poor part of the town. At the time of my visit he was lying on his back in bed, with his head thrown back on the pillow and his legs drawn up. His face wore an expression of suffering, he was troubled with severe frontal headache, and when touched or moved at all he cried out with pain, "Oh, my head!" The intellect was clear, and there were no other head symptoms. The skin felt harsh and dry, the temperature in the axilla was 100·2°; the pulse was remarkably slow, only 56 in the minute, full and at the same time easily compressible; the tongue was slightly furred, the bowels constipated, and there had been vomiting. I examined the chest with some difficulty, owing to the pain caused by moving him, and ascertained that in front there was some dulness on the right side; no crepitation, but the breath sounds were harsh and the expiration prolonged; behind the dulness on the right side was specially marked at the base. The urine was not examined.

The following day we saw him again. The pain in the head was even more acute and incessant, otherwise his condition was about the same. The pain was constant, always referred to the frontal region. The intellect was quite clear; he was able to read books and answer questions; beyond a sluggishness of the pupils to light there was nothing to indicate any impairment of function in the cranial nerves. He was able to take his food, and there had been no vomiting since our last visit. The pulse was still very slow. The position of the head was most remarkable, thrown back on the spine as in tetanus, and on making an examination we discovered that he was actually resting on the occiput and sacrum, and that the hand could be easily passed under the arch of the spine. On calling that evening to take his temperature, I found this opisthotonos even more marked; it was constant, and entirely unaccompanied by convulsive attacks or other tetanic symptoms.

On the next day his condition was about the same, and it being quite impracticable to have him properly nursed at his own home, it was considered desirable he should be moved into the General Hospital. This was accordingly done the same afternoon. His death took place on the next day, Saturday, August 28th.

Mr. Anderson, the resident surgeon of the hospital, has kindly furnished me with the following notes of the post-mortem examination:—On removing the skull-cap slight congestion of the membranes was noticed, and when the brain was removed a distinct swelling was observed on the under-surface of the right temporo-sphenoidal lobe, which had been noticed when removing this lobe from the middle fossa. Fluctuation could be very distinctly felt at this spot. On making a section, an abscess was found, which contained about an ounce of thick creamy pus. It had burst internally into the right lateral ventricle, which was also found filled with pus. The brain-substance around was so softened as to be diffluent, and in the neighbourhood were some small red spots from extravasated blood. The abscess had not given way in any other direction. The membranes at the base of the skull were normal; there was no disease whatever of the petrous bone, or any of the other cranial bones. There was nothing abnormal about the heart. A number of pleuritic adhesions were found on the right side of the chest. There was congestion of both lungs at the base; otherwise the organs appeared healthy. The liver, spleen, kidneys, and intestines were all normal.

The above is a brief account of the case as it came under my notice. I will now proceed to give such facts relating to its history as I have been able to ascertain after careful inquiry, together with a few observations on the points which appear to me most striking.

J. B——'s father and mother are living and well; his eldest sister died at the age of nine; he has one other sister and a brother living, both of whom are in good health. He had measles when a child, and is said to have had an attack of modified small-pox about seven years ago, but he showed no marks of it. He never had scarlet fever or any other illness, nor did he at any time in his life suffer from earache or discharge from the ear. Until a little more than a twelvemonth back he may be said to have enjoyed very good health. He was a bright and diligent scholar, and his attendance at school was never interfered with by illness. At that time his health began to fail. Some three or four months before he had entered upon a situation as stable-boy in a gentleman's house at Sneinton, near Nottingham, and after a little while they noticed that he was disinclined for work, low-spirited, given to sleepiness, and that he frequently complained of headache; his appetite also was poor. It was supposed, however, that these symptoms were attributable to his having overgrown his strength, and as his work was by no means of an arduous nature, and his mistress took a very kind interest in him, he was allowed to continue his employment, and, in fact, remained in the situation until three months before his death. There is no account of his having been laid up with any chest affection, but his aunt, with whom he lodged, says that last autumn he complained a good deal of his chest being tender and that his breath was short. During the time he was in service as stable-boy there is no hint of his having received any blow on the head, though I have questioned everyone who had to do with him closely on the subject. Previous to this he was under the observation of his father, who says most positively that he never suffered from any accident except a very slight one four years ago. The details of this he gave me. The boy was in a cart on his knees, leaning against the back board; it gave way and he fell with it, but saved himself from tumbling out by catching at the side. He was struck in the mouth and cut his lip, but there could have been no loss of consciousness, even of the most temporary kind, as after washing his face he went on as before. It would be unnecessary to mention this apparently trifling circumstance except to show the extreme improbability of his ever having received a blow on the head sufficient to produce concussion. It has already been said that he never had any earache or discharge from the ear; it should be also mentioned that he never had a whitlow, glandular suppuration, or abscess of any kind.

---

[12] Med. Chir. Trans., 1879, p. 327.

So much for the previous history. Coming now to the circumstances of his illness, which terminated fatally on August 28th, the onset of the more serious symptoms may be said to have dated from the beginning of June. He had been ailing before in the way above described and doing but little work, but now the headache became more constant and severe, and he had to lay up a good deal, though he was not altogether absent from work. The pain in the head was chiefly through the temples; he was attacked with giddiness occasionally, but he does not seem to have had any fit or loss of consciousness; drowsiness was also a prominent symptom, and there was a good deal of difficulty in arousing him from sleep.

On July 15th (six weeks before his death) he had very decided rigors, so marked that his mistress thought he was suffering from the ague. Very shortly after this he was sent to the Convalescent Home at Mablethorpe, in Lincolnshire; and whilst there Mr. Campbell, the medical officer to that institution, informs me that he was very apathetic, suffered severely from headache, accompanied by constipation and occasional vomiting, the sickness always being checked as soon as the bowels were cleared out. He returned from there to his father's home in Nottingham on Thursday, Aug. 19th. It is noteworthy that he made this long and fatiguing journey alone, and that at the end of it he was able to walk part of the way from the station, a distance of about half a mile. Greatly fatigued, however, with the exertion, he stayed in the whole of the next day (Friday). On Saturday he felt better, went out a little way, and spent some time talking to a friend in the market-place. On the Sunday evening, while sitting at tea, there was a sudden accession of pain to the head which obliged him to take to his bed, and which remained constant until death took place with the symptoms detailed above.

There are several features of interest in this case both from a pathological and clinical point of view. In the first place, there seems to have been no adequate cause for the abscess; no affection of the internal ear, no fracture of the skull, no thrombosis or diseased condition of the dura mater of the sinuses, no concussion (at least, no evidence of such), no pyæmia or suppuration in other parts of the body. Unless, indeed, the pleurisy, from which he appears to have suffered about a year before, may have had some connexion with the formation of the abscess (a thing difficult to conceive), here is a case in which, to say the least, there is no assignable cause. If there be such a thing as idiopathic cerebral abscess, this surely is one! Then, again, the absence of cyst wall, and the diffluence of the brain-substance around, clearly indicate that the abscess was of recent formation, while the occurrence of distinct rigors on July 15th would seem to point to that date as the period at which suppuration took place. If this be so, we must assume that the obscure head symptoms which had shown themselves for about nine months before the onset of the last illness, were not symptoms of the abscess, but simply evidence of the unhealthy condition of the brain-substance preceding its formation.

Clinically, the most remarkable feature of the case was the occurrence of opisthotonos—a symptom which is noted in only one of the cases tabulated by Sir William Gull and Dr. Sutton in "Reynolds's System of Medicine." In this, the sixty-second case, which is recorded by Dr. Ogle, there is said to have been "a slight attack of opisthotonos."

Nottingham.

A Cottage Hospital was opened last week at Keith. The institution, the erection of which has cost about £1500, is to be known as the Turner Memorial Hospital, in memory of the late Dr. Turner, its originator.

ON SOME POINTS IN THE
PATHOLOGY AND TREATMENT OF ACUTE RHEUMATISM AND DIABETES.

By P. W. LATHAM, M.A., M.D., F.R.C.P.,
DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE, PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

(Concluded from p. 48.)

Having suggested the common origin from which glucose and lactic acid may be derived, I will not here stop to consider how they produce their effects, but on the hypothesis that they result from an enfeebled action of the "coördinating chemical centre," proceed to consider whether any remedies can be administered which, combining chemically with their antecedents, will put a stop to their formation, and produce innocuous compounds which are speedily eliminated from the system.

There are two remedies which have a marked effect in lowering the temperature in pyrexia: quinine and salicylic acid. How do they act?

We know that quinine (1 part in 1000) will stop the amœboid movements of the white blood-corpuscles; it will check inflammation and the resulting out-wandering of these white blood-corpuscles.[1] If in the febrile stage, when the size of the red blood-corpuscles is diminished, quinine be administered, the globules resume their normal size.[2] This is due, however, to the fall of temperature, for the same thing occurs whenever the fever heat is lowered by the action of external cold.

If ozonised oil of turpentine be dropped into an alcoholic solution of guaiac resin, no alteration of colour occurs, but if a drop of blood be added, the blue appears at once—i. e., the blood acts as a carrier of ozone from the turpentine to the resin. Professor Binz has found that quinia, even in so small an amount as one part in twenty thousand, has a perceptible influence in preventing this. Similarly when into a dilute watery solution of the sulphate of indigo carbonate of sodium is thrown until the reaction is decidedly alkaline, and a little blood, and subsequently ten drops of ozonised turpentine are added, a green colour begins at once to develop, and in a little while passes into the clear yellow of isatin. In this case also the blood acts as a carrier of ozone, and Binz and his pupil Ransoné have found that quinia also inhibits this action, one part of it added to a thousand of the mixture delaying the change of colour for an hour. That the action of the alkaloid was on the blood, and not on the indigo and guaiac solutions, was shown by the fact that when similar solutions without the blood were shaken in the air and absorbed ozone, the characteristic colourations of its action were produced just as readily when quinia was absent as when it was present. Binz also proved that the red corpuscles were the portions of the blood affected.[3]

It would seem, then, that when quinia is administered internally it acts as an antipyretic simply by inhibiting the action of the red blood-corpuscles, and preventing the transference of ozone or oxygen by them from the lungs to the tissues. By its action in this way, it produces a great decrease in the elimination of uric acid and urea; it prevents therefore the oxidation of living sarcosine. After a thirty-eight-grain dose, Dr. G. Kerner[4] found the urea was diminished one-fourth, and the uric acid about four-fifths.

Quinia passes through the system unchanged, and is eliminated chiefly by the kidneys. Dr. L. Thau in three experiments out of 4·4586 grammes of the alkaloid given, recovered from the urine passed during forty-eight hours, 4·3 grammes, so that only 0·1586 gramme remained unaccounted for.[5]

By its presence therefore in the blood quinia may prevent the oxidation of the various normal or morbid products in the tissues, and so reduce the temperature, but it does not favour the elimination of those morbid products; they still exist in the tissues, and must be eliminated before the part is restored to a healthy condition. As an illustration of this, I may mention that on two occasions I have seen attacks of gout developed whilst the patient was taking small doses of quinia as a tonic; in one case the patient actually predicting that as I had given him quinine, it would certainly induce an attack.

The action of bark differs in some respects from that of quinine. It has been found by clinical experience that in ague 200 grains of bark produce an effect equal to fifteen grains of quinine, that quantity of bark containing less than five grains of quinine. Is this due to the quinic acid which bark contains, the dry distillation of which produces either benzoic acid (Zwenger and Himmelman) or salicylous acid (Wöhler)?

The other remedy to which I have referred—namely, salicylic acid—when introduced into the system must enter into chemical combination with some of the constituents of the tissues. After its administration it appears in the urine partly as salicylic acid, but also as salicyluric acid; in the same way as hippuric acid, after the administration of benzoic acid, is found in the urine.

By combining one molecule of living sarcosine with two molecules of salicylic acid we obtain the elements of salicyluric acid, and oil of gaulteria or winter-green.

$$\underset{\text{Sarcosine.}}{C_3H_7NO_2}+\underset{\text{Salicylic acid.}}{2C_7H_6O_3}=\underset{\text{Salicyluric acid.}}{C_9H_9NO_4}+\underset{\text{Oil of wintergreen.}}{C_8H_8O_3}+H_2O$$

And oil of wintergreen, when acted upon by soda (in the blood), is resolved into sodium salicylate and methyl alcohol.

$$\underset{\text{Oil of wintergreen.}}{C_8H_8O_3}+\underset{\text{Soda.}}{NaHO}=\underset{\text{Sodium salicylate.}}{NaC_7H_5O_3}+\underset{\text{Methyl alcohol.}}{CH_4O}$$

This action, dependent upon the constitution of living sarcosine, may not be impossible, the salicyluric acid and sodium salicylate being eliminated by the kidneys, and the methyl alcohol inducing that diaphoresis and cerebral disturbance which are often associated with the administration of salicylic acid.

But the following hypothesis seems more reasonable. Salicylic acid when taken into the stomach will be absorbed, and pass directly by the portal vein into the liver. What will it meet with there? If we turn to the list of substances in Tables I. and II. about to be hydrated in the liver, we find at the end glycogen and either allanturic acid or alloxan. Alloxan, when acted upon by acids (HCl or H_2SO_4), is, we know, decomposed, the resulting products being alloxantin, oxalic acid, oxaluric acid, the last being transformed into oxalic acid and urea, and this last again into carbonic acid and ammonia. Taking, then, two molecules of glycogen and two of alloxan, we may have under the influence of salicylic acid—

$$\underset{\text{Glycogen.}}{2(C_2H_5O)_2C_2O_3}+\underset{\text{Alloxan.}}{2(CN)(NH_2)(C_3O_4)}+3H_2O$$
$$=\underset{\text{Carbonic ether.}}{(C_2H_5)_2CO_3}+\underset{\text{Cyanic ether.}}{2(C_2H_5O)(CN)}+\underset{\text{Oxaluric acid.}}{(NH_2)_2(C_3O_4)}+\underset{\text{Oxalic acid.}}{3C_2O_3.H_2O}$$

Now, salicylic acid and salicyluric acid both decompose carbonates.

$$\therefore \underset{\text{Carbonic ether.}}{(C_2H_5)_2CO_3}+\underset{\text{Salicylic acid.}}{2C_7H_6O_3}=\underset{\text{Ethyl salicylic acid.}}{2(C_2H_5)C_7H_5O_3}+\underset{\text{Carbonic acid.}}{H_2CO_3}$$

And ethyl salicylic acid, when treated with soda, is decomposed into sodium salicylate and alcohol.

$$\underset{\text{Ethyl salicylic acid.}}{(C_2H_5)C_7H_5O_3}+\underset{\text{Soda.}}{NaHO}=\underset{\text{Alcohol.}}{C_2H_6O}+\underset{\text{Sodium salicylate.}}{C_7H_5NaO_3}$$

Cyanic ether is decomposed by water, assisted by an acid into alcohol and cyanic acid:

$$\underset{\text{Cyanic ether.}}{(C_2H_5O)(CN)}+H_2O=\underset{\text{Alcohol.}}{C_2H_6O}+\underset{\text{Cyanic acid.}}{CNHO}$$

Again:

$$\underset{\text{Alcohol.}}{C_2H_6O}+\underset{\text{Cyanic acid.}}{2CNHO}=\underset{\text{Allophanic ether.}}{C_2H_3(C_2H_5)N_2O_3}$$

And

$$\underset{\text{Allophanic ether.}}{C_2H_3(C_2H_5)N_2O_3}+\underset{\text{Salicylic acid.}}{2C_7H_6O_3}=\underset{\text{Salicyluric acid.}}{2C_9H_9NO_4}+\underset{\text{Water.}}{H_2O}$$

Consequently, according to these formulæ glycogen and alloxan combine to form carbonic and cyanic ethers, urea, and carbonic acid. The carbonic ether is then transformed into salicylic ether, which, passing into the blood, is decomposed into alcohol and sodium salicylate. The cyanic ether is transformed into alcohol and allophanic ether, the last (or it may be some compound metameric with it, and bearing the same relation to it that the isocyanates bear to the cyanates) combining with salicylic acid to form salicyluric acid and water. Consequently, from four equivalents of salicylic acid we have three equivalents of alcohol set free in the blood, and to this, in some measure at least, must be due the diaphoresis and cerebral disturbance. The sodium salicylate and salicyluric acid pass off in the urine.

These formulæ will explain the difference of the action of salicylic acid in diabetes and in acute rheumatism. Alloxan is the first necessary factor, and in acute rheumatism, as there is increased oxidation going on in the muscular tissue, abundance of alloxan is formed. This, decomposed by the salicylic acid, converts the glycogen into the ethers, which are then eliminated as salicyluric acid, and the formation of glucose and lactic acid is prevented.

If in diabetes the coördinating chemical centre is only weakened to such an extent that, though glucose appears in the blood, alloxan is still formed and appears in the liver, salicylic acid will combine with it, decompose the glycogen, and so prevent the formation of sugar. But if the centre is further weakened, so that $(CN)(NH_2)(CO)_3$ the antecedent of alloxan in the muscular tissue is decomposed in the tissue, forming other products, such as oxamide, urea, &c., which escape into the blood, then the salicylic acid alone can no longer decompose the glycogen, and the amount of sugar eliminated from the system would be unaffected by this remedy. In diabetes, therefore, dependent upon organic change in the nervous system, and of some considerable standing, little benefit would probably result from salicylic acid administered alone. A diet rich in nitrogen must be given, in order to produce excess of uric acid, which, oxidised perhaps in the blood, would then furnish the requisite material for the salicylic acid to act upon—

$$\underset{\text{Uric acid.}}{(CN)_2(NH_2)_2(CO)_3}+O=\underset{\text{Cyanamide.}}{(CN)(NH_2)}+\underset{\text{Alloxan.}}{(CN)(NH_2)C_3O_4}$$

Caffein in such cases may theoretically be worth a trial in combination with salicylic acid, since with hydrochloric acid and chlorate of potassium it is converted into alloxan.

If alloxan is formed in sufficient quantity to combine with the glycogen and prevent the formation of glucose, oxalic acid would be formed and appear in the urine; and as regards this, I may mention that in the case of a patient who came under my care in Addenbrooke's Hospital many years ago, suffering from diabetes, and who recovered under a restricted diet, I noticed that whenever his symptoms were improving oxalates appeared in his urine, but disappeared when the sugar increased. I then thought their presence due to the oxidation of the glucose, but the above formula shows that this is only partially the case. The fact appears to have some clinical significance.

As regards the appearance of uric acid and urates in the urine, it may, I think, be shown that if the disintegration of the muscular be in excess of that of the nervous tissue, uric acid will be formed in excess and pass into the blood. If the contrary condition exists there will be excess of some of the biliary secretions and of phosphates in the urine, but this must form the subject of further investigation. Salicylic acid, then, in acute rheumatism and in diabetes enters into chemical combination with the antecedents of lactic acid and of glucose, and so prevents their formation; and in acute rheumatism, by preventing the formation of lactic acid, there is no longer that dilatation of the minute arteries and consequent hyperoxidation of the muscular tissue, producing pyrexia and increased formation of urates, which are accompaniments of the disease. But to effect this purpose the dose in this disorder must be large enough to produce some decided effect upon the system, such as copious diaphoresis, noises in the ears, or difficulty of hearing, and put a stop to the formation of lactic acid. Salicylic acid that has once passed through the portal system has probably comparatively little effect after it gets into the general circulation. Why this is the case does not seem very clear, but in experiments that have been made with benzoic acid, it was found that when the substance was injected into the circulation alone it appeared as such in the urine, and not as hippuric acid. When two grammes of benzoic acid and 30 cc. of bile (which contains glycocine) were injected into the blood of a dog or cat the urine was found to contain a considerable quantity of hippuric but no benzoic acid; with a larger proportion of benzoic acid the excess passed into the urine together with the hippuric acid.[6] Simultaneously with the appearance of the physiological effects will come relief to the joints and muscles. The dose necessary to effect this is rarely less than

---

[6] Kühne and Hallwack's Jaresbericht, 1859, p. 638.

60 or 70 grains, it may be 100, 120, or more. The plan I adopt is to give the true salicylic acid in hourly doses of 20 grains until 60 grains have been taken, and then 10 or 20 grains every hour, watching its effect until the symptoms are relieved, and the patient's joints can be moved without pain. I give it in the form of pills (20 grains mixed with a little pulvis acaciæ and glycerine can be made up into six hard pills). And during the last four years, though I have given it to patients with all forms of heart disease, I have never seen any bad results follow its administration. Given in the form of pill it is, perhaps, absorbed less quickly, but more uniformly, into the circulation. But I have been careful not to use the artificial salicylic acid. This is made by passing carbonic acid into carbolic acid, and is therefore, unless very carefully prepared, liable to contain carbolic acid. "When six or eight grains of carbolic acid are taken in a wineglassful of water a sense of numbness is felt on the lips and in the mouth, followed by a sensation of coolness. Then if the stomach is empty slight nausea and an uneasy sensation in the abdomen follow, with vertigo, ringing in the ears, and slight deafness. The pulse falls in frequency and force, as does also the cardiac impulse, and diarrhœa sometimes occurs."[7] Similar effects to these have been ascribed to the use of salicylic acid, but, I believe, unfairly.

Whilst the remedy appears to relieve and cure acute rheumatism, it is an unquestionable fact that relapses are extremely liable to occur. These, I think, are explainad by the supposition that whilst the formation of the *materies morbi* is prevented, owing to the decomposition of its antecedents, by the remedy; this has no effect in improving or restoring the tone of the "coördinating chemical centre," and in a short time, if the remedy be discontinued, the morbid products are again formed. But give the remedy in much smaller doses two or three times a day until the "centre" has recovered its tone, and then relapses need no longer be feared.

In diabetes large doses of the remedy have been given, but in favourable cases I have found one or two doses of twenty grains reduce the amount of urine one-half in twenty-four hours without raising the specific gravity, the diet remaining unchanged. I give this quantity twice a day, and a third dose at bedtime if the remedy produces no fulness at the back of the head nor buzzing in the ears, and allow the patients plenty of meat, tea, or coffee, and a moderate amount of wheaten bread and milk.

In pyæmia, typhoid fever, or other zymotic disease, where the poison is acting on the blood itself as well as affecting the various nervous centres, salicylic acid (if the theory I have advanced be approximately true) can have comparatively little beneficial effect.

Cambridge.

IVORY EXOSTOSIS IN BOTH EARS SUCCESSFULLY REMOVED BY OPERATION.

By GEORGE P. FIELD, M.R.C.S.,
AURAL SURGEON TO ST. MARY'S HOSPITAL.

(Concluded from page 46.)

THE next case I have to mention is one of true ivory exostosis in both ears, similar in almost every particular to the one I have published.[1] That patient, Dr. G. M——, can now, Oct. 1880, hear perfectly well in both ears, and has never had any trouble with his hearing for the three years since the operation. Moos of Heidelberg has recorded a somewhat similar case. In an excellent book published this year[2] the author, after stating that these growths do not return when removed (Rindfleisch), goes on to say "that the ivory exostoses of the skull, owing to their hardness, are generally excised with extreme difficulty by means of saw and chisel,[3] and the violence involves very great danger." This, I think, is self-evident. I hope in the next edition he will be able to mention the operation by means of the drill, of which the following is another example.

A. S——, aged thirty-one, a gentleman in good health, came to consult me, Dec. 1879, by the advice of Dr. Symes Thompson, complaining of severe deafness, attributable to a compact growth of bone filling up both ears. He stated that as long as he could remember he had suffered from ear-ache from time to time. In 1866, when a midshipman in the Royal Navy, he first observed he was becoming deaf, and began to suffer increasing pain in the ears, but does not remember ever having any discharge from them. He attributes his deafness to sea-bathing, and states that at times in hot climates he "almost lived in the water." In 1870 he came home from China and consulted various medical men for his deafness, whose general opinion seemed to be that he would "grow out of it." Year after year he gradually became more deaf, till at length his "ears almost closed up," and, thinking nothing could be done for them, he was compelled to retire from Her Majesty's service. On Dec. 16th, 1879, he placed himself under my care. Both ears were closed by a bony growth, which was found to be a large ivory exostosis, and in each ear they arose from the posterior wall of the external auditory meatus. He heard the watch only when in contact with the right ear and about two inches from the left. My colleague, Mr. Edmund Owen, saw the case with me the next day, and agreed in thinking that the only chance of his ever hearing fairly well again depended upon an operation for the removal of a portion of the bone. The case presented exactly similar features in almost every respect to the one I have already published. In each instance the disease was not hereditary, and there was no history of gout or syphilis; there was no pain, but a most distressing feeling of fulness and pressure in the ears was experienced, causing great discomfort and uneasiness, together with tinnitus aurium. The growth filled up both ears; the tumours arose from the posterior wall of the meatus; they were of ivory consistence, adamant-like growths of the petrous bone, and extended from about a quarter of an inch from the orifice to within a short distance of the tympanic membrane. I therefore decided to operate with the American dental engine. This instrument can be used with comparative safety even on a tumour thus awkwardly situated, but it can readily be understood that, from the narrowness of the canal and from the close relation of the brain and other important structures, great care is necessary. Mr. S—— postponed the operation for a month, in order, as he expressed it, "in case anything went wrong, that he might have a merry Christmas first."

On Jan. 29th the patient was placed under chloroform, and I proceeded to drill through the growth in the right ear. Here let me state that to perform the operation I have found that it is necessary to have the help of three assistants—one to give chloroform, one to work the treadle of the engine, and one to hold the steel guard in the ear, which I use to prevent as much as possible any risk from the slipping of the drill when in motion.[4] Help is required also to sponge and to syringe with cold water, to keep away the blood which fills up the meatus with great persistency, and often prevents, for a time, a view of the bone. I worked away steadily for fifty minutes, and at last succeeded in getting a fine drill through the growth. For the reasons before assigned, the greatest caution is necessary, and the operation would require considerable time, even if the part to be pierced proved to be less solid. On Feb. 11th I enlarged the opening, the patient being forty-five minutes under chloroform. On March 2nd I operated for fifty-five minutes on the left side in a similar way, and in this ear I found two subsequent operations necessary—one on March 24th, lasting forty minutes, and one on April 17th, half an hour.

I will describe as shortly as possible the operation. The patient is placed on a high couch four feet from the ground, with his head resting on a pillow, and the side to be operated on must be well propped up towards a good light. It is necessary to have the patient placed as high as this, as the dental engine is adapted to a high chair, and so consequently the drill will not reach anyone placed on an ordinary sofa. The handle of the drill or the holder of course might be made longer, but that would involve constant stooping on the part of the operator, which in such a long operation is best avoided by this high position of the patient. Chloroform is then administered, and an assistant holds a steel guard in position round the growth, the guard having been made beforehand to fit the exostosis. Messrs. Weiss and Son made me for my first operation, and which answered admirably, a soft metal guard of copper, very thin, and small enough to pass between the growth and the anterior wall of the meatus. In fitting it, I bend one end to the exact shape to pass behind the growth on the right side, and the other end to pass behind and exactly fit the left exostosis. When I have thus got the shape of both growths, a guard exactly corresponding to the softer metal is made of steel, which at the time of the operation can be readily placed in position, and prevents danger in no small degree. I generally begin with a small drill, and subsequently enlarge the opening with a larger instrument.

---

[1] THE LANCET, July 20th, 1878.

[2] The Principles and Practice of Operative Surgery, by Stephen Smith, M.D., of New York.

[3] Heinecke of Erlangen has successfully operated by gouge and mallet; but in that case there were suppuration and granulations on the membrana tympani.

[4] Made by Weiss and Son, already described in THE LANCET, July 20th, 1878.

I have not found it necessary to cut through the skin first, before using the drill. I proceed at once to make a small hole by the side of the steel guard, avoiding the base of the tumour, as there is nothing to indicate the direction, and a slip would be attended with the utmost danger to the life of the patient. It must be remembered that very often the operator is working in the dark, for whatever means he may adopt blood will be sure to fill up the meatus. If he succeeds even in making a way through the base of the growth, he may find himself in a very unexpected and unenviable position. With the steel guard firmly fixed in place, I have found it best to work very slowly, constantly taking out the instrument to sponge or syringe away blood, and thus for an instant or so get a view of the bone. The operation, necessarily very tedious, is by no means an easy one, and even with much care and caution bestowed upon every detail, unforeseen *contretemps* may arise.

I have just stated that I consider the help of several assistants necessary; an accident occurred to impress this on my memory. In the last operation on the left ear one assistant was absent, and the consequence was I had to hold the guard and work the drill myself. Unfortunately, somehow or other, the guard slipped and I injured the membrana tympani, and set up slight facial paralysis. This facial paralysis, what did it mean? I at first thought I had touched the chorda tympani nerve, which is a branch of the facial; it winds forwards above the tendon of the tensor tympani, between the malleus and incus escapes through the Glasserian fissure, and descends to unite with the gustatory nerve, and terminate in the tongue. One or two cases have been related (see Burnett, p. 506) where irritation of the chorda tympani has been said to cause facial paralysis. In my case I may have touched the chorda tympani, but then it seems to me that the tongue alone would be affected, and not the muscles of the face. In my patient the mouth after the operation was drawn slightly over to the unaffected side. A sure sign of injury to the facial nerve. The patient confirmed this view by saying next day, "What I complain of most, doctor, is that I can't whistle." I feel sure that I must have touched the inner wall of the tympanum and the aqueduct of Fallopius, which covers the facial nerve, and wounded or slightly grazed the latter. And this was done when the guard slipped, notwithstanding I was working with the greatest care, proceeding very slowly and holding the drill so firmly that I thought it impossible I could go wrong, but an eighth of an inch was sufficient to pierce the membrana tympani and touch the opposite wall. Luckily, I had great power over the instrument; my arms ached from the constant and firm grip I had used in holding the drill. It was the least touch, and that was all, and I knew at once the mischief I had done.

I am happy to say that, by the help of galvanism and careful treatment, the patient recovered from the effects of the paralysis, and the perforation in the membrana tympani closed. The operation itself is one of extreme difficulty, and any serious complication in carrying it out adds largely to one's anxiety. The patient afterwards did remarkably well, and regained his hearing in both ears.

I think that in all communications of this kind every detail should be recorded and every mistake fairly acknowledged. Accidents, however careful the surgeon may be, must occur occasionally; if they are admitted unhesitatingly good may come, for it renders others less likely to fall into the same error.

In conclusion, I am thankful to be able to record a most satisfactory result.

Lower Seymour-street, W.

DR. JAMES WEAVER has, we regret to learn, been compelled by failing health to resign his appointment as medical officer of health to the Longton Corporation.

TREATMENT OF EMPYEMA BY IRRIGATION AND ASPIRATION.

BY W. W. MOXHAY, M.R.C.S. ENG.,
SURGEON TO THE ROYAL BERKS HOSPITAL.

I WISH to place on record a case of empyema treated by a combination of irrigation and aspiration, with perfect Listerian precautions, according to Fraentzel's description at page 717 of the fourth volume of Ziemssen's Cyclopædia. It may be that mine is the first so operated on in England, and Fraentzel himself only quotes eleven.

My patient, a boy aged eight, was operated on on July 16th. His pleura was washed out twice a day until Aug. 19th, then once a day to the 22nd, and on the 29th the wound was healed, and the lung had expanded well all over. The respiratory murmur came close to the ear on every portion of the surface of the chest on this (the left) side, and there was barely a quarter of an inch of difference in the measurement of the two sides. There had been no fetor all through. At first simple distilled water was used, then a weak solution of iodine, and latterly carbolic acid solution (two grains to the ounce). The fluid used was always of the temperature of 100° or 103° Fahr. By a Nélaton's tube, with several apertures, the fluid was let into the posterior part of the cavity of the pleura from a glass funnel somewhat raised above the level of the wound, which was near the mammillary line between the fifth and sixth ribs, and by another tube also going to the back of the cavity, and attached to a cross-acting syringe, the fluid was drawn out and discharged into a basin until cleared from all pus or lymph.

I should just like to remark that in trying to get up some statistics, I was foiled by the curious mixing together in various writings of cases of serous, fibrino-serous, and purulent effusions, under the heading of empyema. Should such things be?

This case was three miles from my house, and I never should have been able to carry out the details, which took up much time, without the kind and able assistance of Mr. B. Brookes of Sonning.

WESTMINSTER HOSPITAL.

PNEUMONIA; EXTREME PROSTRATION, WITH LOSS OF CONSCIOUSNESS; CRISIS ON THE EIGHTH DAY, AND CONVALESCENCE ON THE TWELFTH; TREATMENT BY ALCOHOL; REMARKS.

(Under the care of Dr. STURGES.)

THE notes from which the following is abstracted were taken by Dr. Gristock, medical registrar.

William E——, aged twenty-five, warehouse porter, a stout muscular man, of temperate habits and good personal and family health, was admitted on Dec. 7th, 1880. For some six weeks he had been under treatment for enlarged tonsils, but his general health had not suffered, and he had kept at work as usual. On the evening of the 4th, and again on the 5th, he had had repeated rigors, together with cough, stitch in the right side, and difficult expectoration of hitherto uncoloured mucus. He had now kept his bed for three days. His aspect was depressed; respiration 34; temperature 104°; pulse 132, full and compressible; tongue moist and red. There was still severe pleural pain. The sputum was rust-coloured, viscid, and scanty. The base of the right lung yielded the usual consolidation signs, with as yet very limited area of percussion dulness;

moist râles were audible throughout both lungs. On the second day dulness at the right base, reaching upwards nearly to the lower angle of the scapula, together with œgophony and distant yet still distinctly tubular respiration indicated some pleural effusion on the affected side. The general condition was more depressed: there was still much pain from stitch, with absolute sleeplessness; respiration 44, temperature (midday) 104·6°, pulse 132, urine of sp. gr. 1024, containing distinct trace of albumen, with no marked deficiency of chlorides. There was great difficulty in getting the patient to take nourishment, excepting milk; beef-tea he altogether declined, and mutton broth was substituted. He was treated with ammonia salines, and, fomentations and poulticing failing to relieve the chest pain, five leeches were applied to the seat of it, followed by hot fomentation. By these means this particular symptom was in great measure removed. On the third day, however (being the fifth from the first rigor), the patient was notably worse. He had been restless and delirious during the night, utterly sleepless, and breaking into sweats. At the time of the visit the face was bluish; the lips and ears were distinctly cyanotic; signs of general bronchitis were still very distinct, the râles in places approaching the subcrepitant; pulse was 144, and respiration 44, temperature at midday 103·8°. It was now deemed necessary to give brandy, and during this day four ounces were taken. That night was restless and sleepless, like the others. Delirium was sufficiently active to make a special nurse requisite; the temperature, meanwhile, continued to fall, and this midnight (of Dec. 9th, or the fifth day) was 100°. He was now given bark and ammonia in place of the saline draught. Passing over the 10th (or sixth day of this disease), during which he continued in much the same state, still wholly without sleep, delirious, and with trace of albumen in urine, the 11th of December found him semiconscious, passing urine in bed, much cyanosed, moving about restlessly, not answering, and hardly to be recalled to himself. The tongue was now dry, and sordes were collecting on the teeth. There was much sweating; the temperature was 101·8°; pulse 140; respiration 46, at the time of visit, but both pulse and breathing varied much from hour to hour at this period. In this extreme condition he was ordered half an ounce of brandy every half hour (thus taking twenty-four ounces of brandy during twenty-four hours). Directions were given that in case of increased difficulty, or rate of breathing threatening death by apnœa, he should be at once bled to from six to eight ounces. During the night of this seventh day this condition actually occurred, insomuch that preparations for bleeding were made. Owing, however, to the circumstance that the lancet is less accessible now than formerly, some delay arose, the urgency became less, and bleeding was not actually performed. On the 12th, the eighth and, as it presently appeared, the critical day of the pneumonia, the patient was delirious and irresponsive. Respiration was 34; pulse had fallen to 126; and temperature to 99·4° He still passed urine unconsciously, and the symptoms of typhoid sinking were hardly less; the physical signs had not changed. He had now been five days in hospital entirely without sleep; but on this afternoon, at the time of the visit, was observed to be drowsy. The half hour doses of brandy were thereupon suspended. He fell into his first sleep, and, as may truly be said of cases like his, awoke safe. The change was at once recognised in his aspect and manner, and even the precise hour of this critical change. On the 13th (the ninth day of illness) it was reported that he had had a quiet night, sleeping well; his pulse was 100; temperature 99·4°; respiration 26; urine free from albumen. He was rational, and drowsily answered questions. The next day redux crepitation was heard, and the tubular was exchanged for bronchial breathing. The bronchitic râles were now but partial, and over portions of both lungs respiration was free and natural. It was now obvious that the active stage of disease was over. All medical treatment, including brandy, was stopped by the 14th, and by the 16th, the twelfth day of illness, the man was convalescent, and almost all signs, whether of lung consolidation or bronchitis, had passed away. It was observed, however, that for several days longer the face remained somewhat dusky, and that what may perhaps be called without objection the severe shock of the disease was not recovered from with quite the same celerity which marks the return to health after a pneumonia of ordinary character. Still, on the seventeenth day from his first rigor, being the ninth from the extremest severity of his illness, the patient was up and about almost in his usual health.

Remarks by Dr. Sturges.—We have here an example of pneumonia of unusual severity, yet which in the end underwent its critical change with remarkable suddenness, eight days being occupied by the advance of the disease, and hardly four in reaching convalescence. Two points especially call for short notice—(1) The delay and the manner of crisis, with the sudden termination therewith of the bronchitis, no less than of the pneumonia; (2) the indications that the case afforded for prognosis and for treatment.

1. The area of lung consolidation was not large, nor did it notably spread. But the accompanying bronchitis was much more extensive than is usual in pneumonia, implicating both lungs, and reaching in places to the smallest tubes. Nevertheless, the onset, the course, and the termination of the affection were such as belong to pneumonia, and not such as belong to bronchitis. Especially was this shown by the fact that when the crisis came the lung recovered at once and altogether, the signs of bronchitis disappearing almost as soon as the signs of consolidation. It is true that we have bronchitis more or less in every pneumonia, and that the physical signs of the two are apt to disappear almost together; but in a case like the present, where bronchitis is exceptionally extensive, and in both lungs, while there is but a single patch of consolidation, there is room to question whether we have not a secondary or bronchial and not an idiopathic pneumonia; whether, in other words, we are not to expect a lengthened course and gradual changes such as bronchitis shows, rather than a limited course and sudden amendment such as pneumonia shows. In such circumstances a consideration of the origin and general features of the illness is all important. If in these respects the case conforms, as it did here, to the well-known pattern of true pneumonia then, however extensive the bronchitis, there is yet ground not only for expecting crisis at the usual period, but also for hoping that with this event the bronchial affection will disappear along with the pneumonic. *Bronchitis when coupled with pneumonia in this wise departs from its own rule of gradual recession, and conforms to that of its associate.*

The crisis was late—namely, on the eighth day,—and the fall of temperature was gradual: "a defervescence by lysis." According to some definitions, therefore, there was no crisis at all. The temperature on the morning of the eighth day, when the man was unconscious and threatening to die, was not appreciably lower than on the same evening when he awoke from his first sleep, and it became certain that he would live. For three days, indeed, the body heat had been falling, while all the most ominous symptoms—the prostration, the passing of urine unconsciously, the drying of the tongue and teeth—had been accumulating, and the physical signs had shown no change. We may get just such a fall of temperature when death is impending, and this might seem to be the case here; yet never was there a more sudden arrest of active symptoms. We could tell the very hour when the fever left him, and the transition from immediate present danger to the mere exhaustion of a past conflict was seen first in his face. It is most common, indeed, for the temperature to fall suddenly through several degrees at or about the time of crisis, but we see that this is not always so. *The temperature chart may sometimes give no indication at all of the most marked crisis.*

2. What should have been the prognosis in such a case as this, and how far was it influenced by the treatment? It happens sometimes that with just such general symptoms as those we have here there is not merely a patch of consolidation, but a whole lobe or more is solid; or, otherwise, that the consolidation is not towards the base but at an apex. In such cases, while we wait and hope for the crisis, we are fearing all the while that the actual condition of the lung may be one of rapid disintegration unrecognisable as yet by any physical sign. There is less room for such fear in a case like the present. Let the hepatisation be of small area, at the lower rather than the upper part of the lung, and not spreading, the illness new and sudden, and the patient temperate, of good general health, and not an infant or an old man, and however grave the general symptoms the natural tendency to recovery is so strong that we can hardly place a limit to it. Where else in disease is there anything like it? We are sometimes struck with the sudden termination of a specific fever, but there still remains the prolonged convalescence of such fever. Where but in

true pneumonia do we find a patient blue and gasping and insensible one week and well the next? Such being the nature of the disease, nothing can be more hazardous than the drawing of conclusions as to the results of treatment. The most we can say for certain is that pneumonia, on the whole, has fared better since we have ceased to treat it with remedies. Suppose this man had been bled at the time when bleeding was actually proposed, how admirable an example would he have seemed to furnish of the good of bleeding? And so of the alcohol. It is easy to attribute too much to it. Yet two things may, perhaps, be safely said under this heading. One, that in most cases of pneumonia of this gravity some substitute or other for food is urgently needed, since food itself, in whatever form, can no longer be taken; the other, that the stimulation of alcohol pushed just so far as to produce its earliest toxic effect of narcotising seems to meet the needs of a prostration happening on the very eve of crisis, and which is wakeful and actively delirious. At the same time the nature of this need for alcohol, liberally administered for a short period, in an emergency like this, whether as medicine or as the best substitute for food, would imply the needlessness of it in all cases of pneumonia where suitable nourishment can be given in sufficient quantity. It is quite certain that ordinary pneumonia recovers perfectly well without a drop of alcohol.

NEWARK HOSPITAL.

HYSTERICAL SPINAL AFFECTION OF TWO YEARS' DURATION; CURED BY CORRIGAN'S IRON.

FOR the following notes we are indebted to Mr. J. D. T. Reckitt, house-surgeon.

Alice D——, aged twenty-five, dressmaker and single, was first seen on May 20th, 1878, when she stated that until two years before, when she had a fall, spraining her back a little, she had always enjoyed good health. She was first attended at her home. She kept her bed, but had a healthy appearance, though the expression of her countenance was melancholic. She had been treated in the hospital, and had also been under treatment at home for what she stated was spinal disease, the treatment including blisters to the spine, various liniments, and, lastly, crutches; but all to no purpose. The nature of the case was suspected to be hysterical, and in answer to inquiries the patient said she had severe pains almost everywhere, not excepting even the ends of the finger-nails, and added to this, a sympathising mother dilated very largely upon the extreme suffering the patient underwent. She had not been able to walk for several months, but her appetite had continued pretty good. She slept badly, and had much headache. It was therefore determined to apply the actual cautery, and the patient was assured that she would be able to walk in two months' time.

On May 25th, assisted by Mr. J. Sheppard, Mr. Reckitt made six impressions—three on either side—in the spinal fossæ, from the commencement of the dorsal region downwards. The patient complained of considerable pain, and she nearly fainted. It was decided to reapply the iron in a week's time if there was no improvement.

On June 2nd she appeared so depressed and reluctant to have a reapplication, that it was deferred a week; and accordingly, a week later, six more impressions were made on either side, but below the former. She was ordered to get up.

On the 16th she felt a little better, but still had a little pain and slight headache. She was ordered to try to walk with help.

On the 23rd she said she was improving slowly. She was told that probably another application would be necessary.

On July 7th she was downstairs, and had walked several times with help.

On August 20th she presented herself at the hospital, having walked up a distance of half a mile with her sister's aid. Much better, and walked fairly.

On the 30th so much improved that she was discharged.

Remarks.—The apparent total inability of the girl to walk when first seen, and the rapid effect of the heroic measure adopted, would appear to prove that hysteria—or rather, perhaps, malingering in a hysterical subject—was the main feature in the case; and also that the treatment, though somewhat cruel, was the only means to make such an obstinate individual use her ambulatory powers, and to assure her of her ability to do so.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

A Series of 172 Antiseptic Abdominal Sections.—Radical Cure of Varicocele.

THE ordinary meeting of this Society was held on the 11th inst., J. E. Erichsen, Esq., F.R.S. President, in the chair. The subject of antiseptics as applied to peritoneal surgery—principally ovariotomy—was again under discussion, a paper by Mr. Knowsley Thornton being read; and Dr. Bantock took the opportunity of once more urging his objections to the "Listerian" method. A short description of a new method for the radical cure of varicocele, by Mr. Henry Lee, was also read.

Mr. KNOWSLEY THORNTON read a paper "On 172 Antiseptic Abdominal Sections, with remarks on the causes of death in the fatal cases," of which the following is an abstract. After some remarks as to the details given in the printed tables which accompanied the paper, the author pointed out certain further information which it is desirable should accompany statistical tables of operation cases. First: an account of all cases of abdominal tumours seen during the time covered by the tables, but not operated upon, with the reasons why no operation was performed. Second: the highest temperature and pulse, with the day of the operation upon which they were respectively recorded. Such additional information is necessary in order to show the success of the individual surgeon in dealing with ovarian or other similar disease, and the general progress in this branch of surgery, and also to show the well- or ill-doing of the cases which recover after operation. The fact that all the cases had been treated on Lister's method, and nearly all by the complete intra-peritoneal ligature, was dwelt upon. Common methods of treatment in a large series of cases being especially useful in extending knowledge by affording material for comparison with other methods, the importance of accurately following the teachings and practice of Lister, to the exclusion of so-called "modified Listerism," was insisted on. In the author's hands the *pure Listerism* had reduced the mortality in the most common operation in the tables—ovariotomy—from 23·94 per cent. to only 4 per cent., a result altogether beyond the mere improvement to be expected from increased experience in performing the operation. The question of drainage, by means of Keith's improved form of Koeberlé's glass tube, was then discussed, the small mortality in the last 75 ovariotomies (4 per cent.) being claimed as a proof that drainage is unnecessary if Lister's method be perfectly carried out in abdominal section, comparative statistics being given to prove the same conclusion. The question of selection of cases was alluded to in relation to two of the three deaths in the last series of 75 cases; both were apparently hopeless, but were given the last chance; and both, though open to question as to completion, were included among the complete operations. The question as to what cases should be called complete or incomplete was then discussed. A comparison of the mortality in simple and difficult cases (it is *nil* in the author's hands in the former), in the cases tapped and not tapped, and in those which had only one or both ovaries removed was also given. The causes of death in the fatal cases were then given in some detail, and the bearing of the antiseptic method on the mortality was illustrated by a division of these cases into *three* groups. The danger arising from the transfixion or opening of a diseased Fallopian tube was pointed out as a possible cause of septicæmia—a question also important in dealing with uterine fibroids. The incomplete ovariotomies and other operations in the tables were discussed, and, passing to the treatment of uterine tumours by abdominal section, the author pointed out the difficulties in the application of Lister's method to those cases in which the uterine cavity is opened, and showed from his own statistics that, whereas in cases in which the cavity was not opened the mortality was only one in eight (and that one a very exceptional case in many respects), in cases in which the cavity was opened three out of four died. The general conclusions drawn from the whole 172 antiseptic cases were as follows: 1. Simple cases recover under Lister's method, with a certainty previously unknown. 2. There is less fever, and convalescence is more rapid, than under the old method. 3. The success obtained in the more complicated cases is in proportion to the exactness with which the antiseptic method can be applied to the individual cases. 4. The accidents and complications occasionally following operation, such as hæmorrhage, for example, are more easily overcome in aseptic cases. 5. There are difficulties and some dangers in the application of the method, and the more experience the individual surgeon has in it, the more readily he foresees and avoids these, and the more complete becomes his success in applying it. In a few concluding words the author pointed out how much peritoneal surgery owed to Mr. Lister, and how much more to Mr. Wells; without the untiring energy and success of the latter it would never have been in the position to benefit by the method of the former.—The PRESIDENT, in inviting discussion, drew attention to the introduction into this paper of the subject of removal of the uterus, which opened up a new field of inquiry into the claims of antiseptics, the views held on their merits and disadvantages in ovariotomy being almost irreconcilable.—Dr. BANTOCK began by referring to the debate which had taken place at the last meeting of the Society, and criticising the remarks made by Mr. Thornton on that occasion. He maintained that his own experience, though comparatively small, was sufficient to prove the inefficiency of Listerism. Mr. Thornton's reference to his (Dr. Bantock's) hospital statistics before they had been published was unusual, and if, instead of quoting the last year's figures, he had given those of the previous year, he would have found that the rate of mortality as between his cases and Mr. Thornton's was reversed. The opinion he held that carbolic acid was injurious was shared in by many, for some of the most eminent Continental surgeons had attributed fatal results to its use. In considering the subject of drainage it must be remembered that drainage is always applied to the most severe cases, and to say that in such cases death is due to the use of the drainage-tube is to beg the question. In his own practice the daily diminution of the discharge showed that the drainage-tube did not excite suppuration; and the specimens of fluid he showed on the last occasion proved this, for they were perfectly aseptic. He believed tapping to be most injurious, and would say that it should never be done unless the operator were prepared to follow up the procedure by removal of the cyst. It was harmful, not because of its liability to cause septic poisoning, but because of its leading to inflammatory changes in the cyst. He had removed a cyst (not previously tapped) where the fluid was putrid; the drainage-tube was used, and the temperature fell at once after the operation. He did not believe at all that septic matter could be introduced through tapping. That suppression of urine was more frequent since antiseptics had been used was shown by the fact that it was only once met with by Mr. Spencer Wells in 800 cases; and he himself (Dr. Bantock) never had a case of suppression until he adopted the Listerian method. Dr. Keith's statistics, showing a mortality of 1 in 26 without antiseptics and 1 in 24·5 with antiseptics, were significant. Dr. Bantock concluded by showing that the consumption of ice at the Samaritan Free Hospital had risen considerably since Mr. Thornton's introduction of the ice-cap and his employment of Listerism, and he thought this fact was opposed to Mr. Thornton's statement that there was less fever since the adoption of Listerism than before.—Mr. HULKE asked Mr. Thornton if he would state precisely what he meant by Lister's own method. Mr. Lister had, no doubt, greatly modified his method, and it would be satisfactory to know exactly the details as now carried out.—Mr. THORNTON said the procedure was as follows:—The abdomen is washed by the nurse before the operation with a 5 per cent. solution of carbolic acid, and a cloth soaked in this solution is lightly bandaged on until the operation begins. All the instruments, ligatures, &c., are placed in trays containing this solution, which is diluted with warm water to 2½ per cent. shortly before the operation. The strength of the solution in the spray bottle is also 5 per cent., which is diluted by the steam of the spray-producer to about 2½ per cent. The sponges (always well cleansed after each operation by ammonia and by sulphurous acid—1 in 8) are kept in a 5 per cent. solution, and during the operation are washed in warm water, and then in a 2½ per cent. solution. Gauze is applied directly over the wound, is strapped on, and not removed until ten days after the operation, by which time the wound will (in 99 cases out of 100) be found healed by the first intention, so that it is not necessary to use the spray in removing the ligatures. Gauze is again put on, and the patient goes out with the wound quite healed.—Mr. HEATH congratulated Mr. Thornton upon the plain way in which he had given the facts of all his operations—especially for including his uncompleted operations in his tables. But why were no cases given beyond June last? Ten years ago he held office at the Hospital for Women and performed and witnessed many ovariotomies. He had been pleased to find that Mr. Wells and his colleagues at the Samaritan Free Hospital had come round to the views which were then held at Soho-square—viz., that preliminary tapping was bad, and that ligature was the best method of treating the pedicle. The results they then had were very good. It was remarkable that in all Mr. Thornton's fatal cases there were adhesions; for this proved the truth that if the case be a simple one it does well. Ovariotomy might be compared with lithotomy, where, if the stone be a large one, the chances are against recovery. So in ovariotomy, if the cyst be very adherent, the chances of a fatal result are the same whether the case be treated by drainage or by antiseptics. Therefore he believed that as good results might be expected without the use of the spray as with it; and in his own experience the wounds healed readily; far different from the cases where the clamp was used, when patients used often to go out with the wound unhealed.—Dr. HEYWOOD SMITH, alluding to the removal of uterine fibroids, especially of the intramural class, when symptoms are more urgent, asked whether in such cases oöphorectomy should not be practised, as it seems to give some hope of the arrest of growth of such tumours. The introduction of antiseptics had certainly reduced mortarity in cases of old vascular adhesions, which before the days of antiseptics were often a source of danger from the oozing of blood into the peritoneum.—Dr. CHAMPNEYS pointed out that statistical tables dealing only with ovariotomy were somewhat misleading, for they take no account of those cases which are passed over as unfit for operation, and which by rights should be placed on the side of the fatal cases. Every encouragement should be given to surgeons to operate in all doubtful cases, disregarding the influence this might have in raising the rates of mortality; for cases were met with in which after death it was seen that the tumour could easily have been removed.—Mr. THORNTON disclaimed any intention of entering into a repetition of the debate which took place at the last meeting. The statistics he then quoted from Dr. Bantock's practice had been mostly published by that gentleman in a letter to one of the medical journals. The apparently excessive consumption of ice, on which such stress had been laid, arose from the great waste due to the storage of ice at the Samaritan Free Hospital; and it was not found to be necessary to keep such a supply now, for the ice-cap was very rarely used. He did not think anything would be gained by entering into controversy on the matter after the exhaustive debate at the last meeting, but preferred to wait until fresh facts were brought before the Society. If the fluids shown by Dr. Bantock were really aseptic it would prove that the air of the hospital—and, indeed, the air of London—was purer than the air of Mont Blanc when Professor Tyndall made his experiments. He no longer used any "protective," for Mr. Lister does not use it for wounds of which the edges can be kept in apposition. The reason why the tables included no cases of the past six months was simply that the paper had been written for some time, and included other abdominal sections up to that date (June). He did not imply that all the bad cases died—indeed, under antiseptics a large percentage of bad cases recover. He agreed with Mr. Heath as to the inutility of tapping, and the value of ligatures, and had early come to that conclusion when seeing cases treated by tapping and by the clamp. He hoped that some day the subject of operation for uterine fibroids would be discussed. He had avoided mention of oöphorectomy—an operation which he was sorry to see was being coupled with ovariotomy, whereas it was a far simpler measure, and the indications for its performance had yet to be defined.

The following is an abstract of a paper, "On the Radical Cure of Varicocele," by Mr. HENRY LEE:—The operation advocated in this paper is that of removing a portion of the anterior skin of the scrotum, and subsequently dividing the veins which are to be obliterated. All the steps of the operation are conducted through the wound made by the removal of the skin. The veins are compressed temporarily, so as to prevent hæmorrhage, and then divided. The cut orifices of the veins are sealed with the black hot cautery, which, if of proper temperature, is allowed to adhere to them for five or six seconds. The ligatures and needles used in compression are then removed, and the edges of the skin brought into apposition from below upward by carbolised sutures. Union by first intention takes place more or less perfectly, and the patient is allowed to follow his usual avocations in three or four days.—Mr. PEARCE GOULD described an operation that he had performed for the radical cure of varicocele during the last two and a half years. It consisted in passing a loop of platinum wire round the spermatic veins subcutaneously, and then connecting it with a galvanic écraseur, and making it burn its way through the veins. In all he had performed it eleven times, two of the cases being incomplete, the other nine having resulted in cure without accident. The advantages he claimed for it were its safety, simplicity, painlessness, and efficiency, and the fact that the operation is limited to the diseased parts. He considered Mr. Lee's operation as more complicated, and held that the wound of the scrotum was liable to œdema, and even suppuration; and being closed by the continuous suture, there was no outlet for any effused serum. The removal of part of the scrotum has been shown to be ineffectual for the cure of varicocele, and he doubted if it were needful if the occlusion of the veins were satisfactorily secured. He thought it hardly safe to allow patients to get up and move about so soon as three or four days after such operations on veins, but preferred to wait until the clots were firmly adherent, and the divided ends of the vessels securely closed.—Mr. LEE, in reply, said that although he had now employed the actual cautery in a very large number of cases, he had never had a case of septic poisoning following its use. He attributed this to the complete closure of the veins—the small as well as the large—effected by it. It also effectually sealed the arteries; and if the operation is fairly done there is no oozing whatever. The wounds heal without any sloughing. His object in interfering with the scrotum was to prevent any return of the varicocele.

At the close of the meeting Dr. Heywood Smith exhibited a new apparatus for actual cautery just brought over from Matthieu of Paris, the invention of a M. de Carter, a great improvement in some respects on Paquelin's. There was no bottle to carry about, which not only required the aid of a second person, but was liable to be upset and to give rise to an inconvenient flare, the temperature could easily be regulated by a screw attached to the instrument, and there was also no need for a spirit lamp. The whole apparatus itself was more portable and also less costly.

Reviews and Notices of Books.

Report on the Scientific Results of the Voyage of H.M.S. "Challenger" during the years 1873–76, *under the command of Capt. Geo. Nares and Capt. Frank Thomson.* Prepared under the superintendence of Sir C. WYVILLE THOMSON, F.R.S. Zoology I. Published by order of Her Majesty's Government. Longmans; Macmillan; Simpkin, Marshall, and Co.

THIS magnificent volume contains the first instalment of the Reports on Zoology, which are the results of the expedition of the *Challenger*, and the plan adopted is undoubtedly that from which the greatest benefit can accrue to science. The *Challenger* was sent out with Sir C. Wyville Thomson in charge of a civilian staff, by whom the specimens captured were, as far as possible, preserved, classified, and arranged. The *Challenger* was a corvette of 2306 tons, fitted with engines of 1206 horse power. The guns she formerly carried were for the most part discarded, and she was modified to suit the special requirements of the expedition. Three gentlemen were associated with Sir C. W. Thomson—Mr. H. N. Moseley of Oxford, Mr. J. Murray, and Dr. V. Willemoes Suhm, a young naturalist of great promise, who appears to have won the esteem and regard of his colleagues, and who unfortunately died from an attack of acute erysipelas on the voyage home. Subsequently considerable assistance was obtained from the services of Mr. F. Pearcey.

The voyage lasted three years and a half, and on arriving at home or previously, as opportunity offered, the immense accumulations of material were placed in the hands of experts to arrange or distribute when old, and to name and classify when new. In this way it is obvious every advantage will be taken of the stores obtained. The work is expected to extend to ten or twelve volumes of zoology, to which will be added an introduction containing a narrative of the voyage and all necessary hydrographical details, and a volume devoted to an account of the meteorological observations taken by the naval scientific staff on board. In the present volume the general introduction to the Zoological series of reports has been undertaken by Sir Wyville Thomson himself, and occupies fifty-nine pages. It is succeeded by a Report on the Brachiopoda obtained during the voyage by Thomas Davidson, which occupies 67 pages, and is illustrated by 4 plates. Then follow in succession a Report on the Pennatulida by Albert Kölliker (41 pages and 11 plates); the Ostracoda by G. Stewardson Brady (184 pages and 44 plates); the Bones of the Cetacea by William Turner (45 pages and 3 plates); the Development of the Green Turtle by W. K. Parker (58 pages and 13 plates); and, lastly, a Report on the Shore Fishes collected during the voyage by Albert Günther (82 pages and 32 plates).

The first and most interesting fact that has been established by this expedition is that in corroboration of what had been previously ascertained from the cruises of the *Lightning* and of the *Porcupine*, and in opposition to the views entertained by even such eminent naturalists as Forbes, there is no actual depth-limit to animal life, but that at depths of upwards of three miles, under a pressure of two and a half tons to the square inch, with a temperature close upon the freezing-point, and probably in utter darkness, animal life is still abundant, and all the principal types of marine invertebrata are represented. Wallich has even shown that the much despised Bathybius, when brought up from these great depths, exhibited signs of motion. The area of the great ocean basin is enormous, and is estimated by Sir W. Thomson at one hundred millions of square miles; and he is satisfied that the nature and distribution of the special fauna of this area may be brought with comparative ease within the limits of human knowledge.

The implements employed in the dredging operations were an ordinary dredge with wire rope, which was connected with india-rubber accumulators, to relieve sudden strain, and a donkey engine to haul it up. Sometimes a well balanced trawl, fifteen feet in beam, was used instead, and with great success. The pressure was so great that the wood of the beam was materially affected. In one instance when a pine beam was used, the wood was compressed till the knots stood out a tenth of an inch beyond the general surface, and on another occasion the beam was crushed as if it had been passed between rollers. The quantity of wire rope of various sizes taken out was very great. They had 10,000 fathoms of 3-inch rope on board, and expended 4200 fathoms; 31,000 fathoms of 2½-inch rope, of which they expended 27,100 fathoms; and 15,000 fathoms of 2-inch rope, of which they expended 10,860 fathoms. They were supplied with 22 trawls, and expended 16. The greatest depth dredged on any occasion was 4575 fathoms. The proceedings adopted were very regular and systematic. A single dredging operation occupied the whole day. Steam was got up at daybreak (the ship running under sail during the night), and the ship was hove-to during the morning watch, and a sounding taken. The exact depth, the nature of the bottom, and the bottom temperature having been thus ascertained, and a sample of the bottom water procured, the dredge (or trawl) was put over after breakfast, and the line slowly veered to about 4000 fathoms. In from two to three hours the movements of the accumulators indicated that the dredge had reached the bottom, and it was allowed, with all precautions, to drag for an hour or two. The operation of heaving-in then commenced, and continued for four hours or more, according to the resistance from the weight of the dredge or the state of the weather, the usual rate being about one foot a second. When the number of 100 fathom marks on board indicated that the dredge was nearing the surface the naturalists congregated on the bridge, and preparations were made for its reception. As it was usually in the afterpart of the day when it arrived, lanterns were sometimes required. Sieves were used to separate the animals of various sizes, and in hot climates the specimens brought up were at once registered, and put into spirit, though by so doing many opportunities of observing in detail the colours, structure, and consistence of the tissues of the animals were lost. Animals brought up from great depths were always dead. The ship was fitted with an excellently arranged naturalist's room, with an almost unlimited supply of instruments, many thousand wide-mouthed phials, and thousands of gallons of pure spirit; and, as occasion offered, large quantities of material were sent home from distant stations, as from Bermuda, Halifax, the Cape, Hong Kong, and Japan, and yet several thousand specimens in bottles, cases, casks, and jars were brought home, each specimen having the number of the station at which it was obtained, written indelibly on parchment, dropped into the same jar. The breakages were extraordinary few in number, only four vessels being broken out of 5000.

It would appear that the food of many of the groups of the abyssal fauna is the globigerina ooze, which constitutes the floor of the ocean through a large area. This globigerina ooze is so named because the foraminifer named globigerina enters largely into its composition, but with it are associated members of the group of Orbulina, Pulvinulina, Pullenia, and Sphæroidina. All these animals live near the surface of the ocean, but after death drop to the bottom, the organic matter contained in their tests constituting the chief part of the food of the creatures living at great depths. The abyssal fauna living at depths below 500 or 600 fathoms is remarkably uniform; all the classes and most of the leading orders of marine invertebrata are fully represented, but their representation is not in the same relative proportion as near the surface. Thus, the Gasteropoda and Lamellibranchiata are rare. An order of Rhizopods closely allied to the Radiolaria are largely represented, and have been named by Haeckel the Phæodaria. A large series of starfish related to Archaster are found, which recall many fossil forms; also a prominent family of regular urchins, the Echinothuridæ, exist, long known only by an obscure fossil from the chalk. A group of the Holothuriadæ, named the Elasmopoda, is very conspicuous. There are also many crustacea and many fishes, the latter presenting peculiarities in structure that enable them to be easily distinguished from shore fishes, and being especially characterised by the delicacy of their tissues, which easily break down on dissection, and either by the largeness of their eyes or the absence of these organs.

A general examination of the geological evidence, coupled with an examination of the fauna of the abysses of the ocean, has led Sir W. Thomson to the conclusion that the great meridional depressions of the earth's crust now occupied by the ocean date from the period of its original cooling. From the Silurian period up to the present time there has been a continuous ocean with mean bottom temperature oscillating about the freezing-point; and during all this time an abyssal fauna, of whose existence we have evidence in every rescued page of geological history, must have migrated continuously, becoming slowly changed during the lapse of immeasurable time, with the slightly altering phases in the distribution of sea and land. Slowly, very slowly, movement takes place in the vast masses of water. From the polar regions a stream runs constantly towards the equator, displacing the warmer water of the tropical regions, which is driven with equal slowness towards the poles, and owing to the southern pole being colder than the northern, the chief mass of cold water is supplied from this hemisphere, which correspondingly affects the fauna, the majority of the animals supplying evidence of their derivation from a southern source. In the last paragraph of his preliminary observations, Sir W. Thomson states that the study of the abyssal fauna refuses to give the least support to the theory which refers the evolution of species to extreme variations guided only by natural selection—a remark that Mr. Darwin has criticised severely, as being not only a misrepresentation of the view generally understood by the term "theory of evolution," but also as being in opposition to the entire results of the expedition, which seem if anything to establish the continuity of animal life.

Of the several reports we have little to say, since their interest lies in the description and representation by means of lithographs of new or rare species. The figures are beautifully executed, and no expense has been spared to make them complete. The descriptions are of course technical, and as each series has been placed in the hands of the most distinguished naturalists, they will constitute the types to which all specimens in future obtained will be referred.

Dr. Davidson remarks that although the number of Brachiopods brought home was great, only thirty-one species are represented. The greatest depth at which any living Brachiopod was obtained was 2900 fathoms, but they do not abound at depths beyond 500 fathoms. The new species obtained appear to have been few; though one, the Terebratulina Wyvillii, is the finest and largest species of the subgenus Terebratulina hitherto discovered, either in the recent or fossil condition. Professor Kölliker, in describing the species of Pennatula submitted to him for examination, refers for anatomical details to his own classical work upon them, but gives a new classification, which has been rendered necessary by the examination of the new species discovered.

Dr. Stewardson Brady's report on the Ostracoda is very complete. He finds that they are very rare or absent when the ocean bed consists of red clay or globigerina ooze. Fifty-two species were obtained in all, nearly all of which are represented in the forty-four plates which accompany the memoir, and which are most beautifully drawn and printed.

The memoir of Professor Turner gives, in short compass, the characters of the bones of the various skulls, teeth, vertebræ, and other parts of the osseous skeletons that were captured in the course of the expedition.

The account of the development of the Green Turtle given by Mr. Kitchen Parker is of course perfection, and the plates illustrating the paper are coloured in the effective manner familiar to all who have seen his drawings in the Linnæan and other Transactions.

We have so recently drawn attention to Prof. Günther's study of Fishes that we need only say that the present memoir is the well from which his more general description has been drawn, and that it supplies the facts on which his generalisations rest.

In looking over the pages of this volume, and remembering that it is the first instalment of the results obtained during the voyage, we cannot but feel satisfied with the work done. It reflects the highest credit on all concerned. The liberality of the Government (for such an expedition costs many thousand pounds), the excellent appointments of the vessel for the purpose intended, the judicious selection of the staff, both civil and scientific, the unanimity and harmony with which all the required observations were carried out, and, lastly, the interest and value of the results obtained, are all points on which the organisers of the expedition may be sincerely felicitated. Sir Wyville Thomson may be especially congratulated on having secured the services of such able and willing collaborateurs, and on the rapidity with which he has brought the first results under the notice of the scientific world. We hope soon to have the opportunity of examining the second volume.

WITH the close of 1880 the *Revue Mensuelle de Médecine et de Chirurgie* (Paris: Germer Baillière) completed its fourth year of publication, and the number declaring this fact announces also the separation in future of the *Revue* into two parts—viz., a *Revue de Médecine* and a *Revue de Chirurgie.* Each journal will appear, as heretofore, on the 10th of the month. The *Revue de Médecine* will be edited by MM. Landouzy and Lépine, the "direction" consisting of MM. Bouchard, Charcot, Chauveau, Parrot, and Vulpian. The *Revue de Chirurgie* will be under the direction of MM. Ollier and Verneuil, the acting editors being MM. Nicaise and Terrier. In their remarks upon these changes the editors state that they believe the interests of science will be best served by the alteration. The *Revue Mensuelle* took a high position from its first appearance, and it has been the medium of publication of many important memoirs, as may be seen by reference to the index covering the whole period of four years, which is appended to the last number.

PILGRIMS AT MECCA.

ACCORDING to the report of the Turco-Egyptian Sanitary Commissioners at Mecca, the number of Mahomedan pilgrims collected in and about the holy city (Mecca) during the pilgrimage just ended, amounted between the 3rd and 16th November to two hundred thousand persons; composed of natives of Turkey, India, Egypt, Morocco, Arabia, Syria, Persia, Java, &c. The greatest mortality amongst them after their first arrival in Mecca, about 4th November, was twenty-one daily. During the sacrifices on Mount Arafat the maximum mortality reached thirty-one daily, and in Mecca after their sojourn on Mount Arafat it reached thirty-seven daily; the total deaths from 4th to 19th November being set down at two hundred and ninety-six.

The number of animals—sheep, camels, and other beasts of burden—collected in the neighbourhood of the pilgrim encampment is estimated at a figure far exceeding the number of the pilgrims; and when we remember that this enormous host of people and animals are collected together in one vast encampment without any organized sanitary police to compel compliance with the orders of the sanitary authorities, the number of deaths is not surprising.

The same report states that during four days no less than a hundred thousand sheep were slaughtered in the valley of Mouna, and that, notwithstanding the establishment of thirteen slaughter-houses, fourteen trenches for the interment of the carcasses of the slaughtered animals and the débris, five hundred and five public latrines, the sanitary authorities found themselves utterly unable to enforce their use for want of a proper sanitary police.

The diseases given in the report as the cause of death in the above two hundred and ninety-six cases are rather vaguely stated as fever, diarrhœa, and small-pox; fever, one hundred and eighty-three; diarrhœa, sixty-four; small-pox, forty-nine. As a simple mortality statistic, this statement is perhaps satisfactory enough; but as a scientific medical sanitary question, it would be interesting, and perhaps useful, to have a little detailed correct information on the supposed causes, exact nature, and characters of the fevers and diarrhœa prevailing in such a vast encampment of people of so many different ages and nationalities; also of the amount of sickness and its nature, means of treatment, &c., as the report gives merely the number of deaths.

The crowd is now dispersed, and the pilgrims are on their homeward voyage, about six thousand having passed by way of Suez up to Dec. 4th for Egypt, Morocco, and other places in the Mediterranean and Levant, and, so far, it is gratifying to learn that the general health is satisfactory. About half this number, according to official accounts, has been carried by British steamers—making an average of from 500 to 600 passengers per vessel—five British vessels having arrived at Suez with pilgrims up to the above date, one French, three Turkish, and one Egyptian.

With regard to the utter want of any organised force, and the supineness of the Government to grant proper assistance to the sanitary delegation to enforce attention to hygienic rules, the commissioners say:—"We have had on former occasions to urge a reform of the existing system, and we again bring forward our proposition of last year—viz., to prohibit all sacrifices among the masses of pilgrims in camp; to transfer the slaughter-houses and ditches for interment and débris from the Valley of Mouna to Wady-el-nar; to establish a military cordon outside the camp; to prohibit the introduction of living sheep among the pilgrims. Our conviction is that without some reform such as this we shall have to report in the next few years a lamentable amount of sickness in this valley (Mouna), as the pilgrimage will soon take place during the hottest months of the year."

It is evident from this report that the sanitary commission which, we are told, is sent yearly to Mecca to superintend the sanitary condition of the pilgrims, to prevent the development and propagation of contagious disease, is entirely unsupported, and utterly helpless to perform the work for which, we are told by the Turkish and Egyptian Governments, it is sent. Their faith is not in prevention—not in hygiene, but in quarantine! Instead of organising and carrying out effectually measures to prevent the outbreak of disease, nothing is done till some contagious disease becomes rampant—then is raised the cry of the slothful "quarantine," bringing with it unhealthy lazarettoes, huddling together of ships' cargoes of pilgrims, amongst whom disease already exists, or if not will soon be propagated from an infected lazaretto, vexatious taxes on shipowners to meet extravagant quarantine dues, questions of litigation, sacrifice of life, health, and money, interruption of commerce, and trouble to everybody, while all might probably be prevented.

As the European powers have interested themselves in ameliorating the internal administration of Turkey and Egypt, a little active interference, to introduce properly executed hygienic reforms for the two hundred thousand pilgrims of different nations who collect annually at Mecca would seem to be urgently required, to prevent disease among them there, and its propagation by them to other countries. It will do little towards that to learn that official letters have been sent from one foreign-office to another, to say a sanitary commission has been sent. A commission of five Turkish and Egyptian medical men was sent last year, but with what result their report shows, entirely without an executive under their own control.

THE DEAF AND DUMB ASYLUM.—The annual meeting of the governors and subscribers of this charity was held on Monday at the Cannon-street Hotel, Mr. Charles Few, the treasurer, presiding. The report of the committee stated that they had decided to give a specific trial to the pure oral system for educating the deaf and dumb, as resolved upon at the recent congress at Milan. With that view they purposed to elect an increased number of boys and girls at their election this month, and to form classes so as to give the new system a complete and fair trial with an entirely fresh arrangement of teachers. The expenses for the year were £11,291, being £289 in excess of the receipts. The report was adopted.

THE LANCET.

LONDON: SATURDAY, JANUARY 15, 1881.

IT is to be hoped that the metropolitan public have read rightly the moral of Dr. BREWER'S letter as Chairman of the Metropolitan Asylums Board, reprinted from *The Times* in our columns last week. He told us what indeed ought to have been ascertained long ago, to the saving of no little misapprehension, that the Hampstead Hospital difficulty not only has deprived the Board of the use of a large hospital which might have been invaluable for cases of small-pox in the present crisis, but also stands in the way of the Board acquiring new hospital sites and of erecting new hospitals while the difficulty lasts. In other words, the Metropolitan Asylums Board, as at present circumstanced, cannot do more than make the best use possible of its existing accommodation for small-pox cases, and this is practically exhausted, and the present hospital sites it has the possession and use of admit of very little additional accommodation being placed on them for the disease. The hospital accommodation for small-pox which the Board now possesses has exercised little if any appreciable influence upon the progress of the growing epidemic, is wholly insufficient to compete with the epidemic as it stands, and will be altogether swamped as the epidemic approaches its acme. So far as the arrest or sensible limitation of this outbreak is concerned, it must be understood that as regards the isolation of cases in hospital there will virtually be no check. This is greatly to be regretted, but it will do no harm in the long-run if it serve to fix upon the mind of the metropolitan population that, at the best, isolation can but be a measure of protection subsidiary to vaccination—a truth which there is good reason to fear has been largely forgotten from the prominence which of late years has been given to hospital accommodation for isolation of cases of small-pox. Isolation has its place, and a singularly important place, in the measures for dealing preventively with small-pox; but it can never supply the place of vaccination; and, moreover, while isolation in hospital must of necessity be of limited application, vaccination may be and ought to be of universal application. While, therefore, we are, by a series of unfortunate circumstances, deprived for the moment, in face of a growing epidemic, of the important assistance to be derived from ample accommodation for the isolation of cases of small-pox, the more important means of vaccination remains to us, and if it be diligently and duly made use of, may justify us in looking upon the growing epidemic with little anxiety. This is the moral which should be derived from Dr. BREWER'S letter.

The "if" we have made use of above is a terrible word, however, and includes within its two letters all the difficulties of the situation in regard to vaccination. *If* the local vaccination authorities, where small-pox appeared in the east of London, had followed up the individual cases as set forth in the instructions for their guidance in such circumstances by the Local Government Board; and *if* the sanitary authorities had freely co-operated with them, we should not now be in fear of an epidemic of small-pox. *If* the vaccination authorities of the west and centre of London, learning a lesson from the shortcomings of their brethren in the east, would set themselves diligently and fully to carry out their functions, either with or without the help of the sanitary authorities, there need not be the least alarm of the extension of small-pox in any great degree into the central and western districts. But the vaccination authorities are the Poor-law authorities of the several districts, and we know how difficult they are to move unless operated upon strongly by the public opinion of the ratepayers. Hence the "if," under these conditions, becomes a word of very dubious import. Nevertheless, upon the due exercise of the powers as to vaccination possessed by these authorities the safety of the uninfected districts of the metropolis as to small-pox depends, and the arrest of the disease in the infected districts also depends. This should, above all things, be clearly understood. They are responsible for the primary vaccination of infants, and have powers of revaccination, free of cost to the public, of older children and persons of mature age. *If* all the vaccination authorities of the metropolis could be imbued with a just sense of their responsibility, and be brought at once duly to exercise the powers which have been entrusted to them by the Legislature, London might be saved from the small-pox epidemic at the last hour.

But since the great epidemic of small-pox in 1871–72 *revaccination* has assumed an importance in the question of vaccination it had not before possessed, particularly on account of the great number of persons who have been seized with small-pox beyond the age to which the compulsory clauses of the Vaccination Acts apply. It is to this class of persons that the present condition of things in the metropolis has peculiar importance. Their safety rests wholly with themselves, and, assuming that they have all been vaccinated in infancy, an effective revaccination will make them more certainly proof against the disease than if they had previously suffered from it. It is, perhaps, unfortunate that, in view of these older persons, the Local Government Board has not completed its arrangements for the issue of vaccine lymph from the calf (although it is doubtful whether this lymph would be issued for purposes of revaccination alone), but as this lymph can be purchased in the market, it is for the individuals interested to decide whether they will set off personal safety as to small-pox against the price of a charged tube or an ivory point. But one thing is clear, that persons who ought to be revaccinated will act unwisely if they are not revaccinated as early as practicable, not waiting until the full swing of the epidemic (if it is to come) be upon us, when an abundant experience has taught us that it is not always easy to secure an efficient revaccination, partly from a deficient lymph-supply, and partly from the condition of performance of the operation not always being the best.

◆

NOTWITHSTANDING the loss of the Parliamentary Select Committee by the dissolution of Parliament, it may be doubted whether the question of Medical Reform ever stood better before the public or the Legislature than it does today. Changes more or less affecting old corporations are not made in a day. A case has to be made out, and often it takes a ten years' conflict to determine very simple questions. This is more especially true when the questions are more or less technical. Such is the case of Medical Reform. It was natural that statesmen and legislators should have considered that in surgery there was no authority like that of the College of Surgeons, and that in general medical politics all wisdom was to be found gathered round the table of the Medical Council. This delusion has been nearly dispelled. And the public now sees that the College of Surgeons is a corporation and the General Medical Council a corporation of corporations, and that nothing worse can be devised for such bodies than to leave them in undisputed possession of ancient privileges or vague powers without making them responsible in some degree to the profession they represent, and without bringing them into vital co-operation with that profession in its growth and its activity. This is the meaning of the demand that has been so strenuously made for more than ten years for Medical Reform. The inefficiency of the present Medical Council has been most painfully and completely demonstrated. The number of representatives of separate corporations in the Council has been shown to import into debates rather a care about financial matters than about the interests of the public. We notice in another place the action of certain Corporations that practically sell their highest qualifications, and what ought to be their greatest honours, in a way that will be thought almost incredible. Some of the licensing examinations of our best Examining Bodies leave out the most vital subjects; many of these include only a most inadequate attention to the preliminary and general education of the student. In addition to these evils affecting the profession itself, there is great looseness in the state of the law as regards practice by unqualified persons, so that a large number of deaths occur in cases in which the deceased or his friends have been practically defrauded and made to believe that they were being served by a qualified practitioner, when in reality they were being attended by a totally unqualified one.

Such are the evils crying loudly for removal. The most of them have been practically admitted by the two Governments which preceded the present one. It is not credible that the present Government should be less ready to see the case for Reform, or less likely to entertain it. All impressions to the contrary we believe to be unfounded; and we shall continue to believe so until they refuse to bring in or to support a Bill honestly and earnestly dealing with these great evils.

One thing is wanted—a united Profession. And there are special reasons why the Profession should be disposed to act unanimously at the present moment. It is probable that before long the question of Medical Reform will be again before the House of Commons, and will only need the support of the Profession to commend itself to the acceptance of the Government.

◆

WE desire to cherish the hope that good may come out of the evil trouble at Guy's Hospital, not only as regards that institution but others. The question so painfully raised in connexion with the management of this particular charity for the sick poor has been much, and long, vexed elsewhere. There is one fundamental error underlying the widespread dissatisfaction, and it is the cause of all the worry and grievance. The lay committees and administrators of hospitals are jealous of the medical authority which must needs assert itself. In nominal connexion with the older endowed charities are men of the highest social distinction, who accept their position as trustees and governors as posts of honour. They know nothing of the inner working of the institution, and rarely interfere in the deliberations of its governing body, until one day some half-dozen respected members of the executive board appeal to its ornamental colleagues for support, and these personages come down in red-hot zeal to rescue them from a difficulty, or to resist what they are told is an attempted encroachment on lay authority. Matters can never go on prosperously while this system and method of government exist. The existence of an outlying reserve at the call of any party on the working board is a perpetual source of danger. There would be no objection to a tribunal of appeal in case of internal difference of opinion; but the honorary members of a hospital board do not constitute such a tribunal. They are simply voters who may be pressed into the service of the moment by personal influences. It is nearly always against the medical authority this outside might is invoked. There will always be jealousy—that is inevitable; but it would be better to leave the onus of maintaining its supremacy with the minority of any board than to give it the right of calling in special assistance when in difficulties. In these preliminary observations we are trying to get to the bottom of matters, and it is not too much to say that in nearly all the difficulties and differences which develop into scandals in connexion with hospital management the impracticable party—that is, the party which *will not* be constrained to act wisely—is originally in the minority, and would so remain but for the aid of the outsiders, who seem ever most ready to come to the rescue of the wrong.

As we have repeatedly insisted, the medical authority must be supreme in a medical charity. This does not necessarily mean that the governing body should be wholly composed of medical men, or even that the profession needs to be in a majority; but inasmuch as all the work and charity proper to the institution is medical, the chief actors in the benefaction ought to be largely represented on the Board of Management. The point to make good in order to sustain this view of the case is that a hospital is essentially a medical charity. Can this be seriously doubted? The only earnest objectors to the proposition we have just laid down are the religious enthusiasts and ecclesiastical propagandists who regard hospitals as promising spheres for the carrying out of their purposes. With these persons we join issue. Let the preacher occupy his pulpit, and the polemical disputant select any appropriate platform for his work; the hospitals are simply houses of medical treatment for the sick. The spiritual needs and desires of the patients should be simply satisfied by ministers of their own persuasions. A sick chamber is not the place for preaching or teaching. Priests, teachers, and "ministering sisters" are out of place in such an institution, the latter more particularly, because under cover of services to the body they do not scruple to attempt what they are pleased to regard as "service to the soul." It is, in our judgment, wholly foreign to the purposes of a hospital to carry on missionary work within its walls. Medical men attached to houses-of-cure for the sick should make this understood. Nothing can, or must, be allowed to interfere with the effort to cure disease. If the patient desires to see a minister of his own denomination he should have a perfect right to do so; but the sick Churchman should not be irritated by the efforts of the Roman Catholic or Dissenter, or the Catholic be exposed to the zeal of the Protestant, still less should the "Evangelical" be annoyed by the parade of Ritualism, either in words or services, or a special garb worn by the nurses. A hospital is an essentially secular establishment, and it should be conducted by men who are prepared to regard it in this light, and not in any other. With a Committee so constituted there would be little difficulty, because men of business not imbued with any non-natural idea must perceive that a hospital is a medical institution, and can only be rightly administered as such. Take the medical element out of the establishment and nothing remains. This is so obvious that only a preconceived notion of the "opportunity" could possibly induce any sensible person to overlook the consideration, and to give it full effect.

What we mean by the claim of *supremacy* for the medical element is simply that the medical requirements of the sick shall be fully recognised by the Committee of Management. This, of course, implies that there shall be medical men on the board, and in sufficient number to make their influence felt. There is no desire on the part of the medical profession to overstep its province. We do not wish to see physicians and surgeons, as such, entrusted with governing powers. The utmost we ask and claim is that the medical men entrusted with the duty of curing the sick in an institution set apart for that purpose, shall be the judges of what is necessary to render their practice successful. This is surely a very reasonable and simple demand. The house exists for the cure of disease, and the medical staff is appointed to carry out that intention. It follows that the medical staff must select its tools and materials, and generally determine the domestic conditions under which the task confided to it is to be performed. It were idle to argue in support of a proposition so self-demonstrative. Either the claim should be admitted or the enterprise must be abandoned.

The question of the moment is how to secure that the demand we make shall be enforced on those who, having other views of the hospital question than those common-sense enjoins, and looking upon these institutions as "fields" and "mission-houses," are striving to subvert the medical charities of the metropolis and the country generally to their own narrow purposes? A Royal Commission has been suggested. If this can be obtained, good may undoubtedly result from an inquiry. There are, however, certain preliminary considerations which ought to be made plain. First: the Commissioners must include medical men of repute, recognised and trusted by the profession at large. It is vain to hope for a satisfactory issue to any inquiry which is not conducted by men who have a full knowledge of hospital business and the conditions on which alone it can be successfully carried out. There are men in our midst who have had ample experience in hospital service, and yet neither provoked the active antagonism of lay governors nor sacrificed the principle of hospital government on medical principles. Such men have given proof of their discretion and tact, and these are the qualities which it is most necessary, at this conjuncture, to bring conspicuously to the front. Second: any inquiry to be effectual must be exhaustive, and include all the leading hospitals which have large endowments, whether in the metropolis or the provinces. It is especially desirable that the area of the inquiry should be extensive, because while the trouble is widespread, there are scattered throughout the land institutions which thrive and are pervaded by a spirit of contentment, and it is important that the secret of this success should be elicited. To allay all anxiety, give general satisfaction, and make the utmost of the opportunity for the collection of valuable information the field of investigation must be fully covered by the inquiry. Third: the search for evils and causes of friction in the working, and failure in the extended success of medical charities, must be uncompromising. It is as established agencies for the relief of physical suffering, and the cure or amelioration of bodily disease, hospitals require to be scrutinised. No phase of their constitution should be allowed to escape the scrutiny. The method of raising and administering their funds, the mode of selecting their officers, the arrangement of offices and the appointment of persons to fill these offices, with the functions and power of each, require to be studied at close quarters, and in their practical relationship as links in the succession of causes and sequences by which the purpose of the charity is to be carried into effect. If a Royal Commission, constituted in a manner likely to secure these results, and properly furnished and empowered for the business in hand, can be secured, it will do good, but nothing short of a complete fulfilment of the conditions we have advocated can be reasonably trusted, or would be worth the trouble and cost of a trial.

◆

IN the usual acts of volition the mental process is entirely concerned with the results obtained, and takes no heed of the action of individual muscles. In raising a cup to the lips the attention is fixed on the elevation of the hand by the flexion of the elbow, not on the contraction of the biceps, brachialis anticus, and other flexor muscles of that joint. But it is well known that the will can exert control not only over groups of muscles acting together, but upon individual muscles, and, by practice, can cause contraction of muscles formerly not under the direct control of it. Thus, by practice, the biceps can be contracted alone without any other of the flexors of the elbow-joint, each one of the facial muscles can be separately contracted to show its individual action, the scalp can be moved to and fro, or one or other of the muscles of the soft palate can be put into use as desired, and thus its individual action verified. For the most part this power of contracting single muscles independently of the common purposive movements of the body is in abeyance, and cultivated by a few as a study, and by others as an amusement. But it was reserved for a Dr. KJOELSTAD of Christiania to make use of it as a curative agent in certain cases of deformity of the spine, especially lateral curvature. Dr. TIEDEMANN has developed the treatment still further, and Dr. ROTH has recently called attention to it in this country. It is stated that by making patients with lateral curvature of the spine examine their deformity by the aid of a reflecting-glass, a contraction of the muscles which are weakened, and which by their relaxation permit or even cause the deformity, can be excited by the will. By practice these contractions can be made of longer duration, increased in strength, and excited independently of the aid of vision, so that by a simple act of volition these weakened muscles can be set in action, and the deformity corrected or lessened. It is easy to see how the cure of this affection can be thus expedited and aided—for it is not suggested that it is able alone to cope with severe deformities,—and it indicates a direction in which those who have such cases under treatment may derive help. It is in strengthening the weakened structures and exciting to tonic contraction the relaxed muscles that the true cure of scoliosis lies. Spinal supports may assist by rendering such a return of the normal condition more easy of attainment, but alone they are not calculated to prove curative, and there is ample experience to show that when trusted to for more than accessory aid, they not only disappoint, but may even exaggerate the evil they are designed to benefit.

THE annual Report on the Health of the Navy for the year 1879 has just been presented to Parliament. It has undergone some change in form compared with preceding reports, in conformity with the views "expressed by the Parliamentary Committee on Official Statistics," the tables in the Appendix showing the cases, deaths, and invaliding by classes of diseases only, instead of by each disease as formerly, and the professional details in the Report being curtailed as much as possible. It is stated that "it is proposed, as occasion offers, to ask their Lordships' permission to publish any reports of sufficient professional interest which may be received in office." In the meantime these annual reports lose much of their importance to the profession generally by the changes thus introduced, and are of comparatively little value for the study of the geographical distribution of diseases, and of the causes of sickness and mortality in our Navy. During the year 1879 the cases of sickness in the service generally amounted to 1117, the deaths to 8·58, the proportion invalided to 32·96, and the mean number constantly sick to 44·98 per 1000 of the average strength. These ratios are all lower than in 1878, but the reduction in the mortality occurred in that from accidents which in 1878 had been very high owing to the loss of the *Eurydice.* The death-rate from disease in 1879 was ·91 per 1000 above that of the preceding year. In all these particulars, however, there is a reduction upon the average of the preceding ten years. The cases ranged between 856 in the Home Force and 1620 per 1000 in the East Indies; the mortality between 5·37 on the Australian Station and 22·91 on the West Coast of Africa and Cape of Good Hope; and the invaliding between 15·05 from Australia, and 42·42 from the Mediterranean. The cases were under the average of the preceding year on all the stations except the South-East Coast of America, where there was a very trifling excess, and the West Coast of Africa and Cape of Good Hope, where they were 340 above it, but even there the ratio corresponded closely with that of the average of the last ten years. This excess appears to have been to a great extent the result of the service on shore of the Naval Brigade during the Zulu war. Unfortunately "separate returns, distinguishing the sickness of the crews afloat from that of the men employed on shore, have not been furnished," and it is therefore impossible to state with accuracy the influence of this duty upon the health of the men employed. The mortality was higher than in 1878 on all the stations, except the Home, Pacific, and Australian, and in the Irregular Force, but the excess was very marked only on the West African and Cape of Good Hope stations, where it was in a great measure due to the occurrence of small-pox on board the *Boadicea* on the West Coast. The disease appears to have been introduced into her by some Kroomen shipped at Sierra Leone, of whom twelve took the disease and ten died; twenty-four cases and two deaths occurred among the Europeans. Only one of the Kroomen bore marks of vaccination, and he recovered; the Europeans had all been vaccinated. The deaths from continued fever and dysentery were also considerably above the average, and occurred chiefly among the men serving at Fort Chelmsford, Fort Ekowe, and the Lower Tugela. These diseases were attributed to malaria, and to the impurity of the drinking-water, and the dysentery also to the presence of intestinal worms.

We observe with regret a remark at page 3 of the Report which throws a certain amount of doubt upon the perfect accuracy of the returns as regards the causes of death. It is stated that "there appear in the returns 201 entries for tubercular diseases, while 189 were invalided for and 45 died of them; this apparent anomaly is due to the cause, that the men who were first entered sick for other complaints of the respiratory organs were eventually invalided for or died of phthisis, which developed while they were under treatment." Surely this indicates neglect on the part of medical officers, and perhaps also inefficient supervision, as we presume that in the regulations of the Naval Medical Department care has been taken to lay down rules for such an obvious and frequent occurrence as the change in the returns of a patient's disease, either from a correction of the diagnosis, or from the development of another disease during the progress of, or convalescence from, that for which he was originally placed under treatment. We would call the attention of the new Director-General to the necessity for an inquiry into this matter, and the adoption of measures to ensure accuracy in the future.

Tables are given in the Appendix, showing the influence of age, in four decennial periods, on the prevalence of the various classes of diseases, and on the mortality and invaliding caused by them. The following are the results as regards the service generally. Our space will not allow us at present to enter into the details of the various stations and the different classes of diseases.

	Per 1000 of mean strength.		
Ages.	Cases.	Deaths.	Invalided.
Between 15 and 25	1321	6·7	31·01
,, 25 ,, 35	963	9·41	30·75
,, 35 ,, 45	708	12·75	41·03
Above 45	567	18·91	63·96

This shows that the younger men furnish much the highest proportion of cases, while there is a marked progressive increase in the mortality with the advance of age. The proportion invalided is nearly the same in the first two decennial periods, after which, as might be expected, there is a marked increase.

Numerous detailed tables are also given in the Appendix, to illustrate the operation of the Contagious Diseases Acts, not only during the year under review, but also for the whole period during which they have been in operation.

A CORRESPONDENT puts to us a very proper question. It will appear simply incredible to most people that a Medical Authority within the meaning of the Medical Act, and among the bodies privileged to be included in Schedule A of that Act, virtually sells its highest qualification. It is very natural, therefore, that we should be asked if such is really the case. The press of this country has been for some years loud and unanimous in its denunciations of some obscure colleges in the United States—where colleges rise up as mushrooms or as Jonah's gourd, but, alas! do not disappear so quickly—which have carried on a thriving trade in Degrees in all Faculties, selling them to persons who had a few pounds to give in exchange for titles which they were not likely to acquire in the ordinary way. Our own notice of this subject was slightly less loud because of our knowledge that some of our own medical corporations do virtually sell their highest qualification. It is now some years since one of them made, it is said, £10,000 in one year by the virtual sale of its lowest qualification. But the question put to us to-day by a correspondent has reference to the sale of another and much more serious qualification—that of the Fellowship of the Royal College of Surgeons of Edinburgh. In answer to his question we have simply to say that the Edinburgh College does virtually sell its Fellowship. That is to say, if any person already possessed of a licence in Surgery from any Licensing Body in the United Kingdom applies to the Edinburgh College for a Fellowship, and can accompany his petition with testimonials showing that he has not broken any of the lesser commandments, the constitution and custom of the College are such that he will receive its Fellowship on the payment of a certain sum. There is no doubt or mystery about this. It was frankly admitted by Dr. ANDREW WOOD before the Select Committee of the House of Commons. But it is a very discreditable state of the law, and should bring the Scottish corporations into the very front of the army of medical reformers, instead of being, as alleged, in the ranks of the principal opponents. In the medical world a Fellowship of a College of Surgeons implies merit. It implies in the English college an extended education and the passing of a very severe examination. It implies probably a pecuniary outlay of nearly £400, over and above the cost of an ordinary medical education. The possession of a Fellowship is a condition of obtaining office in metropolitan hospitals, if not in provincial ones. Can there be anything out of the region of sacred things more serious than to preserve the point of such a distinction? But here is a Royal College of great respectability and renown actually selling it! So that two men may be competing for an appointment of great responsibility, for fitness for which a Fellowship of a College of Surgeons is thought the best security, and yet in the one case the Fellowship is a real thing, in the other it is entirely unreal; in the one case it has been worked for and won, and in the other it has been—bought! Can there be a greater unfairness than for a Royal College to send a man into a community, to work among other men, with such a piece of tinsel to his name? We regret to say that the Fellowship of the Royal College of Physicians of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow, are to be had on the same easy and pecunious terms, without examination and *in absentia*, as in the case of the Edinburgh College of Surgeons! The working of this monstrous system has just received a startling illustration in the Report of the Sub-committee on Medical Education appointed by the Committee of Council of the British Medical Association. "We may mention the case of a student who presented himself at the Royal College of Surgeons, London, and was rejected. He immediately started for Edinburgh, where he was again rejected. Upon this he went to Glasgow, and passed. He registered as a qualified practitioner, forwarded certain sums of money to Edinburgh, and, as qualified practitioner, was made a Fellow, without further tests, by the very College which had, not long before, rejected him as unfit, by examination, for the licence!" Nothing can exceed the significance of this simple narrative, and it is to be hoped that the Edinburgh College itself — the college of many illustrious men — will take advantage of impending legislation to relieve itself from a position so discreditable and anomalous.

Annotations.

"Ne quid nimis."

PROPOSED AMENDMENT OF THE PHARMACY ACT.

THE Council of the Pharmaceutical Society have for some time been engaged in framing a draft of a Bill for the amendment of the Pharmacy Act, and have just published the result of their deliberations. The immediate cause of the proposed addition to the legislative regulation of the trade is apparently the decision of the legal tribunals by which the action of co-operative societies in dealing in drugs is declared not to be against the law. Its main object is evidently to render such action illegal, and the chief clauses are framed for the purpose of altering the wording of the Pharmacy Act on which the recent decisions were based, so as to exclude co-operative stores from the right of practising pharmacy. As the *Pharmaceutical Journal* remarks, "a challenge is thus thrown down to the several opponents of those interests which the chemist and druggist is convinced ought to be protected. It is a step which means war to the knife with co-operative stores and their stimulators, in regard to the practice of pharmacy."

Opposition to the Bill is anticipated, it would thus appear, by those who propose it, and that their anticipations will be verified is scarcely doubtful. The object of the proposed additions to the Act is, it is frankly admitted, to afford protection to the pharmacists, a protection which, it is urged, they may claim on account of the study and knowledge now demanded of them before they can engage in their occupation. But in their statement of the case and of their expectations one consideration is apparently overlooked. Neither the Pharmacy Act nor the Medical Act was intended for the protection of the class which it regulates; each was for the protection of the public. For the attempt at amendment of the Pharmacy Act in this particular to be successful, it will be necessary not merely to plead the claims of the pharmaceutical chemists to "protection," but to show that, in the practice of pharmacy at co-operative stores under the direction of a qualified pharmaceutical chemist, any danger to the public is incurred. This, we conceive, they will find by no means an easy task.

Some other clauses of the Bill are likely to meet with little opposition, and may be regarded as real amendments. One of these provides that patent medicines containing poisons within the meaning of the Pharmacy Act shall be subject to the regulations as to labeling and otherwise now in force as regards the ordinary sale of such poisons; and it makes the sale of a patent medicine, whether by wholesale or retail, containing a scheduled poison, without due labeling, an offence punishable by a fine not exceeding five pounds on the first occasion, and ten pounds upon any subsequent occasion, upon summary conviction. This is a very desirable provision on account of the great number of fatal accidents which have arisen from the misuse of secret remedies containing poison. By another clause the onus of properly labeling these medicines is thrown upon the makers, not the vendors of them. Another provision exempts all chemists and druggists carrying on business on their own account from serving on juries, a just and reasonable proposal. Widows are left as under the present Act, but the time during which executors may carry on a business on behalf of widows is limited to three years, unless this period is extended by the Pharmaceutical Society.

INDIAN LIBEL CASE.

WE have received from India a detailed report of the judgment in the appeal from the conviction of the magistrate of Allahabad in the case of Hall *v.* McLeod and Wyman. It may be remembered that Surgeon-Major Hall brought a criminal action against the editor and publisher of the *Indian Medical Gazette* for defamation, in imputing to him untruthfulness in an advertisement inserted by him in the *Indian Herald*, soliciting contributions for the Allahabad Eye Hospital, and accusing him of unprofessional conduct in the publication of the advertisement. Judgment was given for the plaintiff in the Allahabad Court, and the defendants were sentenced to a fine, or in default to simple imprisonment. Against this judgment the defendants appealed, on the grounds that the article complained of was not defamatory, but was a fair criticism on Dr. Hall's advertisement, and that it came within the exceptions to Section 499 of the Indian Penal Code on the subject of defamation. It was also pleaded that the Court of Allahabad had no jurisdiction, and that the publication by the defendants had not been proved. The Chief Justice, Sir R. Stuart, gave judgment against the appellants on the two last pleas, but in their favour on the first and most important plea. The conviction, therefore, was quashed. The Chief Justice expressed his opinion that the prosecution had utterly failed, and regretted that it had ever been undertaken. He thought that if the defendants' conduct was made the subject of complaint at all, it should have been tried in a civil and not a criminal court. But while thus blaming Dr. Hall for the course he adopted in bringing a criminal action, and without any previous communication with the defendants, he exonerated him fully from the charge of unprofessional conduct. He says: "For myself, I am far from approving of this article [in the *Indian Medical Gazette*], and I differ in opinion from the writer of it. I think it shows bad taste on the part of the author, and that to some extent it casts a slur on the prosecutor and does him injustice. I consider that Dr. Hall was quite entitled to advertise the claims of the hospital as a public institution. ...... Dr. Hall could have very well afforded to have disregarded the unmerited attack, as perhaps it may be called. He is a gentleman well known and highly respected in these Provinces for his many good qualities and for his professional knowledge and skill, and I know of no officer of Government more worthy of esteem." The remarks of the Chief Justice appear fully to bear out the opinion we expressed when the report of the first trial was before us, that Dr. McLeod had placed himself in an unpleasant position in having made so serious a charge against Dr. Hall, apparently without sufficient inquiry; while Dr. Hall had been deficient in courtesy in having commenced a criminal action against a member of his own profession and an officer of his own service without having first afforded an opportunity of withdrawing the imputations which he had put forth, apparently from a misapprehension of the facts of the case.

PROFESSOR GAIRDNER ON POINTSMEN'S WORK.

PROFESSOR GAIRDNER of Glasgow, moved by recent railway accidents due to faults of pointsmen, publishes a letter in a Glasgow contemporary, in which he details the case which he had treated in the Royal Infirmary in 1872. This patient was a pointsman at Rutherglen station, where from 250 to 300 trains were due every twenty-four hours, or about one train, on an average, every five minutes. Though the intervals at night were long, in the daytime they were such that, in the man's own words, "trains would pass for an hour together as close as they could follow." The work was divided into a day and a night shift, the latter being thirteen hours, the former eleven. The pay was £1 a week. There was no time for meals, which had to be taken while at work. The wonder would be how any man so situated could escape giddiness or some break down in the nervous system. The fact that men do so so often is a wonderful testimony to the principles on which the nervous system is constructed. But, as it happened, this man came to suffer from a nervous complaint characterised by passing insensibility, of which the patient was sometimes quite unconscious. The man said that when his duty was most anxious the disorder was at the worst. Dr. Gairdner thinks the public are to be congratulated on that man having come under treatment. It seems highly probable that in this way an accident was averted. Since then Dr. Gairdner has taken pains to ascertain the rules of French lines, and finds them much more considerate of the limitations of human faculty. On the Scotch line the hours have been reduced to eight, but without special intervals for taking food. The patient got well after two or three months' hospital rest and treatment. Dr. Gairdner sets a good example in publishing this case. By itself it shows the need for more consideration of responsible railway servants. If any of our readers have similar cases in their clinical books they will do well to publish them. It must especially be remembered that in the worst attack in the hospital the patient had no memory of what had occurred. It will be necessary to examine pointsmen for something more than mere colour-blindness.

"SPERMATIC CRYSTALS."

FURBRINGER has examined the composition of the contents of the seminal vesicles and prostatic fluid from fifty bodies, and the prostatic secretion from twenty healthy individuals, and has found that the "sperm crystals" described by Bottcher occur exclusively in the prostatic secretion. They appear to be identical with the so-called Charcot's crystals (which were really discovered by Robin), and which are said by Schreiner to consist of a phosphate of a new organic base. In the secretion of the prostate gland this organic base appears to exist in combination with some other than phosphoric acid, and, for the formation of the crystals, the acid must be furnished either by the secretion of the testicles or by post-mortem decomposition of the walls of the ducts. The clinical significance of the discovery of these crystals in secretions which come out of the urethra is that there is an abundant secretion from the glands of the prostate.

SERIOUS CHARGE AGAINST A MEDICAL MAN

At an inquest held on the 8th inst., at Whitchurch, near Bristol, before Mr. Biggs, Deputy-Coroner for Somerset, a very serious charge was brought against a medical man. According to the evidence, the deceased was a married woman, forty-seven years of age, who for ten years had needed no medical advice. On the 29th ult. she complained of a sore-throat; and as more serious symptoms soon developed, Mr. Lodge was sent for. He promised to come in the evening, and meantime sent a bottle of medicine. As he did not attend, repeated messages were sent to him representing the urgency of the case; and when at length, on the afternoon of the 1st inst., he reached the house, the woman was dead. It appeared that she had been unconscious for some time before death, and that there was suppression of urine. In spite of the fact that Mr. Lodge had not attended the deceased during life, he gave a certificate of death from enteritis. Meantime the case had been reported to the coroner, who decided that an inquest was necessary, and directed Mr. Crisp of Keynsham to make a post-mortem examination. Mr. Crisp, who was assisted by Dr. Roué of Clifton, gave it as his opinion that death had occurred from arrest of the action of the kidneys, probably from exposure to cold. The kidneys were found to be markedly contracted and cirrhotic, and there was no urine in the bladder; the heart was fatty. There was no trace of enteritis. The coroner, in summing up, regretted that Mr. Lodge had not seen fit to be present at the inquest, although he had been informed that it was to be held. He said that a medical man could not be compelled to attend a patient, but that Mr. Lodge should have stated that he was unable to visit the deceased, and thus have enabled the friends to obtain other advice. With reference to the certificate of death, he said that "an act had been done which, if not illegal, approached so nearly the borderland of what was legal and illegal as to be stigmatised as irregular in the strongest sense of the word. If there was one law more than another whose objects were to preserve life and to prevent abuses, it was that law of registration of deaths; and if medical certificates were to be given in this way, it went very far to defeat the whole reason for registration. Such a course was grossly irregular and in the highest degree improper; and if it were passed by in silence it would open up abuses which he hardly dared to contemplate." The jury, in bringing in a verdict in accordance with the medical evidence, expressed their regret that Mr. Lodge did not attend the deceased after promising to do so.

The evidence summarised above appears to set out two charges against the medical man implicated; the first, that although repeatedly sent for, he delayed his visit until the woman was dead; the second, that, although he had never seen the deceased during life, he gave a certificate as to the cause of death. It is a minor point that the post-mortem examination revealed no trace of the certified cause of death. We shall be glad to hear what Mr. Lodge may have to say in defence on both the issues raised.

THE ORGANS OF TOUCH.

M. Ranvier has communicated to the Académie des Sciences a note on the structure of the organs of touch. The study of the exact structure of the tactile organs is a matter of considerable difficulty. Hence some observers have found only nerve-fibres rolled in a spiral, while others have discovered terminal structures, more or less complicated, and Merckel even believed that he had discovered terminal sensory cells. M. Ranvier has found that much light is thrown on the subject by the examination of the structures in newly-born children and young infants. At birth, the nerves of touch may be found to pass into certain papillæ on the palmar aspect of the fingers, immediately beneath the cells of the mucous layer of Malpighi. There they form a network of which the ramifications, although distinct, are closely pressed together. At this time the terminal network which represents the future tactile corpuscle presents no admixture of cellular elements; but, beneath it, there exists a small collection of round cells. By examining the changes of structure in children of different ages, the successive phases of evolution of the tactile corpuscles can be traced. Gradually the cells, at first collected beneath the ramification of nerve-fibres, surround it, and pass in among its branches. The whole soon becomes limited, and thus a tactile corpuscle is formed. Sometimes the corpuscle remains unilobar, but more frequently other lobes form in the same manner as the first, and are joined to it. Hence it is that in young children, as Langerhaus has stated, the nerve-fibres which enter into the composition of the tactile corpuscles are separated by layers of cells. In the course of development these cells become pushed to the periphery of each lobe, and most of them undergo a considerable atrophy. This fact alone suggests that they are not nervous in nature, since the nerve-cells, so far from undergoing atrophy during growth, gradually increase in size up to their full development. Ranvier has never been able to see any communication between the nerve-fibres and the cells in the tactile corpuscle; the ramifying branches of the nerve-fibres, after a tortuous and usually complicated course, end by free flattened knobs.

SALT AND SNOW.

When next a storm of snow falls in the metropolis it may be well to remember that the device of scattering salt on the whitened ground with the view of causing the deposit to melt is simply that of making a freezing mixture. In the rapid change of form from solid to liquid the snow absorbs—to use an obsolete expression—a large amount of heat, no inconsiderable part of which may chance to be appropriated from the extremities of passing foot-passengers. The soles of boots and shoes are not improved by being saturated by the saline mixture, and "the cold strikes" very perceptibly. The police regulation which requires that householders shall clear the snow from the pavement in front of their houses is sufficiently ridiculous, leading, as it does, to the production of such a slippery footpath that those who would walk safely must walk on the road. It will be making confusion worse confounded, and intensifying the nuisance created by a casual fall of snow—not now-a-day a very common infliction—if the thoroughfares are to be converted into baths of "freezing mixture," to the detriment of health and the injury of shoe-leather. It would be worth something to be rid for a while of the incubus of "science applied to health," and the astute refinements of a labouring and laborious civilisation.

NIGHT-WORK AT HOSPITALS AND THE HOSPITAL SATURDAY FUND.

It is reported that the collection of the Hospital Saturday Fund for last year reaches £6604, of which £1598 was raised by street collections, and £5205 by means of *employés*, shops, &c. The total was an increase of £452 on the previous year. This is so far satisfactory, but we agree with the recommendation of the president, Mr. Morley, that the efforts of the Fund should be directed to increasing the amount of the collection in workshops. £5205 is a very inadequate contribution from the working men of London to institutions which exist very largely for their benefit and those of their families. The expenses of the movement have fallen from 27 per cent. to 14 per cent. This, too, is satisfactory. We cannot endorse the suggestion made by the President that the Fund should urge on the hospitals the propriety of opening their gates at night, for the convenience of men employed during the day. At the very least this suggestion requires a good deal of consideration. For one thing, men employed during the day should not, as a rule, go to hospitals; they are not proper objects for hospital treatment, but for treatment by private practitioners or at provident dispensaries. Secondly, hospital work, like all other work, is best done in the daytime. Thirdly, for the run of patients night would be a bad time. On these and other grounds we do not see our way at all to approve of the suggestion, that hospitals should be open for night-work to all comers.

A CURIOUS FACT IN ANIMAL REPRODUCTION.

A CURIOUS fact has recently occurred which throws some light on similar cases reported of the human species, but which have been received with considerable doubt by some authorities. The *Journal de Médecine Vétérinaire de Lyons* states that last April, on a farm in the department of Isère, a mare about ten years old gave birth, at full time, to a foal. Soon after the throes of parturition recommenced, and with assistance another foal was brought into the world. Twin foals are sufficiently rare to cause astonishment at any time, but the astonishment of the attendants was changed into amazement when they discovered that it was not a horse foal they had taken from the mare, but an unmistakable mule. The little creature, unfortunately, and as is generally the case with twins in solipeds, did not long survive its birth. The veterinary surgeon who was subsequently called in made inquiry into the case, and as a result he gives the following explanation:—It is a very common practice in Dauphiné to present the mare, when in œstrum, twice to the stallion, and at a brief interval, believing that fecundation is more certain by this procedure. But, as it seldom happens that the villagers can obtain the services of a stallion which can serve the mare twice with only a few minutes between, or yet a second stallion, and as male asses are by no means scarce, they oftentimes employ one of the latter to succeed the horse. And this is what happened with the mare alluded to.

The case is not absolutely unique, even in equine physiology, however, for Fleming, in his "Text-book of Veterinary Obstetrics" (p. 152), gives six similar instances, and one in which a mare, put first to an English stallion and soon after to a Barb, produced twin foals—one resembling the first, the other the second stallion. It may be noted that, of all the domestic animals, the mare is the least disposed to multiparity.

THE INTERNATIONAL WATER SUPPLY REFORM ASSOCIATION.

ENGLISH travellers have so often denounced the dangers of drinking water in Continental hotels and towns, that the formation of an international society for the special purpose of calling the attention of the governments of Europe to the quality of the water supplied throughout each country, should meet with very general approval, at least among Englishmen. This society, though founded in Paris during the International Exhibition of 1878, may be considered to have only now commenced its first year of practical existence. The movement was originated by Mr. J. G. Jäger, director of the Amsterdam Water Company, who early secured for the association the patronage of their Majesties the Kings of Holland and Belgium. An international Committee was formed, a programme and set of rules drawn up and submitted to the approval of some five hundred delegates at the International Congress of Hygiene, held at Turin last September. Definite rules were then adopted, and the Association Internationale pour l'Eau Potable comes into actual existence with the advent of this year. The honorary presidency was offered to Sir Richard Wallace in consideration of the great services he has rendered in supplying drinking water to the public. The Prince of Wales has also been asked to patronise the association in consequence of the personal interest he has displayed in the question of water-supply. The head-quarters of the society are in Paris, and its organ, the *Revue d'Hygiène et de Police Sanitaire*, is edited by Professor Vallin. Dr. F. de Chaumont of Netley Hospital, and Mr. Edwin Chadwick, C.B., are among the members of the English committee. All persons interested in sanitary reform are invited to join this association. The subscription is fixed at ten francs per annum, half to be sent to the central committee, and the remainder kept for the purposes of local agitation, &c. It will be the business of each national committee to bring every influence to bear upon their respective governments, so that the central authority may exercise its full power in compelling local districts boards, &c., to provide suitable drinking water for the use of all inhabitants. Everyone who has travelled on the Continent, and visited even certain of the most fashionable health-resorts, will recognise the urgent necessity of some such action; while at home in England we are too well aware how much there still remains to be done to save the populations from the dangers of water contamination. For the present, however, it is among the smallest countries in Europe that the Association has met with the most success. We have seen that the King of Holland and the King of Belgium have lent their personal support, and now we learn that an influential Greek section has been formed under the Presidency of Dr. Bambas, and with the mayor of Athens as one of its active members. In France and Italy the Society has received a fair amount of support, but it still remains to be seen whether England will lend any efficient aid.

PHYSICIAN IN ORDINARY TO THE QUEEN IN IRELAND.

WE learn that Dr. Benjamin G. McDowel has been appointed as Physician in Ordinary to Her Majesty in Ireland, in the room of the late Dr. Alfred Hudson. Dr. McDowel is a graduate in medicine of the University of Dublin, a Member of Council and Fellow of the Royal College of Surgeons in Ireland, Physician to the Whitworth and Hardwicke Hospitals, and formerly Professor of Anatomy in the School of Physic, Trinity College, and Surgeon to Sir Patrick Dun's Hospital, Dublin. The appointment is one which is regarded with approval by the medical profession.

THE FIRST TO FEEL THE FROST.

THE first frost or fall of snow, leaving a slippery deposit on the ground, inflicts a fearful impost of toil and suffering on the horses. It does not need a highly sensitive development of the instinct of sympathy to be moved with compassion for the evident misery and injury, the fear and the muscular straining to preserve a footing, entailed on the animals harnessed to heavy omnibuses, and even between the shafts of cabs. Indeed, the cab-horses probably suffer the most, because they are constantly employed on the cross thoroughfares, whereas the main routes traversed by the public vehicles are more readily cleared, or reduced to a quagmire, which, however disagreeable, is not slippery. It is inevitable that there must be a heavy loss of property in horseflesh, as well as the suffering inflicted, due to every sudden frost, or fall of snow. The immediate results may not be great, but the violent straining of muscles which the horse undergoes is not without its persistent consequences. Can nothing be done to prevent this evil? It is strange that the extensive adoption of asphalte and wood pavings has not led to the invention of a shoe which, while affording that protection of the hoof which is supposed to be necessary, shall give the foot a secure hold on the ground. It would seem as if the solution of this apparently not very complex or difficult problem has defied the ingenuity of contemporary talent, as it defied that of our predecessors. We are, of course, familiar with the various devices which have been suggested; but, while looking at them practically, must confess to feeling convinced that not one is so complete a success as to warrant popular use. This is a matter in which medical men, who nearly all employ horses, and are compelled to expose them to heavy risks in all weathers, are especially interested.

TRICHINOSIS.

ACCORDING to a recent report to the Sanitary Committee of Massachusetts, it appears that of 2701 pigs examined during five months no less than 154, or nearly 6 per cent., contained trichinæ. The animals came from different and distant regions, but the majority were from the western States. The same report affirms that rats are affected with trichinosis at Boston to a much larger extent than in Germany. Of fifty-one rats caught in a Boston slaughter-house thirty presented trichinæ. On the other hand, twenty-eight fowls fed in the establishment were found to be healthy. Forty rats taken in another large slaughter-house all contained trichinæ; but of sixty found in different stables only six were thus affected.

In France little consideration has, until lately, been given to the danger of trichinæ in imported pork. At Lyon, however, inspection has been commenced, and has quickly born fruit. An enormous consignment of lard, amounting it is said to 120 tons, was lately received at Lyon from New York. Of fifty specimens examined immediately after arrival three were found to be infested with trichinæ. At Barcelona six cases of death from trichinosis have occurred in three months.

THE MEDICO-CHIRURGICAL SOCIETY.

THE last two meetings of this Society have been practically wholly taken up with papers and discussions on antiseptic ovariotomy, in a great measure travelling over the same ground. We notice that there is another paper announced on the results of 200 cases of this operation, and we are compelled to draw the attention of the secretaries and council of this Society to the serious inconvenience and waste of time entailed by such procedure. It might surely have been arranged for the three papers, if, indeed, they were necessary, to have been read on the same evening and discussed together. It is at least open to doubt how far such statistical papers meet the object held in view by the Society, but to deliberately and by arrangement assign three several sittings to three papers all running on the same lines, is a serious interference with the usefulness of its meetings.

A MEDICAL MINISTER.

THE portfolio of Public Instruction in the Cairoli Cabinet has, after due deliberation, been accepted by Dr. Guido Baccelli, the distinguished professor of clinical medicine in the Roman University. The Italian Legislature, both in the Chambers and the Senate, owes much to the physicians and surgeons who are so numerously represented in either House, but to none more than to Dr. Baccelli. *Sanitas sanitatum omnia sanitas* has been his watchword; and in every measure affecting, however remotely, the public health his voice has always been raised with power and effect. On other subjects he has signally exemplified the advantages which a mind trained in the medical *palæstra* can confer on the legislator, and more than once a ministerial crisis has been averted by the skill with which he brought back an agitated and mutually recriminating House to the merits of the question before it. His tenure of office will shortly, we believe, be marked by the introduction of measures for the improvement of University training in general and of medical qualification in particular—measures which cannot fail to interest those who are engaged in similar reforms among ourselves. Dr. Baccelli, we believe, has no thought of giving up his large consulting practice, but he has resigned the chair of Clinical Medicine, to which Dr. Panizza, his occasional substitute, has just been appointed his successor.

FOOT-AND-MOUTH DISEASE.

A SERIOUS invasion of eczema epizoötica, or foot-and-mouth disease, has taken place, after the country had been free from it for several months. The infection is supposed to have been conveyed by diseased cattle from the North of France, which arrived at Deptford Market some time ago. Thence it was carried in every direction, the fairs and markets being the chief sources of dissemination. It now prevails pretty generally over England, notwithstanding the efforts made to check its progress. It is to be feared that inspection of the cattle markets is often at fault. For the chief metropolitan market there is only one inspector, and as the number of animals crowded together is frequently more than two thousand, it is evident that they cannot be submitted to that careful examination which is so necessary for the detection of the disorder, particularly at its commencement, or in its milder form. The infection can be conveyed by all kinds of media independent of the living animal, and this certainly renders the extension of the disorder far more easy, and its suppression much more difficult, than some other transmissible diseases of animals. It must not be forgotten that the infection can be transmitted to other than the bovine species, and man himself is not proof against it. The milk is the chief vehicle of infection.

PATHOLOGICAL SOCIETY OF LONDON.

THE newly elected President, Dr. Wilks, will take the chair for the first time at the meeting of the Pathological Society on Tuesday next, and, according to custom, will deliver some introductory remarks before the regular business of the Society is proceeded with.

DEATH ON THE STAGE.

A TALE is told of an excited medical student who, while watching the final catastrophe of "Romeo and Juliet," and impatient of the supineness of those who discover the dead body of Romeo, called out, "Hold hard while I run and fetch a stomach-pump." A similar feeling must take hold of any medical member of the audience of the Prince of Wales' Theatre, while watching the death of Mr. Coghlan in "The New Trial." Mr. Coghlan (as Connaro) takes poison, and is some five minutes in dying; while a doctor of medicine (a modern scientific doctor, who has a microscope on his table) stands calmly by without attempting to interfere with the deadly draught, the nature of which we (and probably the doctor as well) were quite unable to diagnose from the symptoms of the patient—symptoms which were of the stage stagey, albeit that they caused no little sobbing and sniffing amongst the audience. Such exhibitions are not pleasing or instructive, and we think that a return to the usages of the ancients, in allowing all deaths to take place out of sight would be a distinct gain to the modern stage.

SEATS FOR SHOPWOMEN.

THE shopping season having recommenced we renew our appeal to the humanity of ladies, and request them to bear especially in mind the under-mentioned large establishments conducted by firms which have intimated their willingness to provide seats for their *employées*, and to sanction the use of them in all intervals of counter-serving.

INTESTINAL BACTERIA.

NOTHNAGEL of Jena has been investigating the organisms found in fæces, and has examined the microscopical characters of five hundred stools in health and disease. He found many microscopic organisms constantly present, but that which was found in greatest abundance was the Clostridium butyricum of Prazmowski (the butyric vibrio of Pasteur, the Bacillus amylobacter of Van Tieghem). It occurred in the fæces in which no starch could be demonstrated. It is probably this which has given rise to the statement that the yeast fungus is often present in the fæces; in point of fact it is very rarely found in the fæces. Riesenfeld and Brieger discovered butyric acid in both the intestinal contents and in stools, and the product is doubtless the result of the growth of these bacteria.

SOME dissatisfaction is naturally felt in Aberdeen at the action of the Endowed Institutions Commissioners in reducing the medical bursaries in the University from twelve to eight. At a meeting of the Aberdeen Town Council last week, Dr. Beveridge especially drew attention to the impropriety of this step, and thought the Commissioners must have misinterpreted the evidence placed before them in reference to the matter. It was ultimately understood that any representation made to the Home Secretary with a view of reversing the decision of the Commissioners upon the subject would have the support of the Council.

AT a meeting of the Norfolk and Norwich Medical Chirurgical Society at Norwich, on January 4th, 1881, the following resolution was moved by Mr. Alan Reeve Manby, seconded by Dr. Bateman and Mr. Cadge, and agreed to unanimously, "That this meeting, reprobating the systematic exclusion of the medical officers from the government of hospitals, tenders its sympathy to the medical staff of Guy's Hospital in the present crisis."

THE Marquis of Bute has expressed his willingness to defray the entire cost of construction and maintenance of a small hospital for Aberdare. The sole stipulation appears to be that the nursing shall be conducted by Sisters of Mercy.

MM. FOURNIER, GOUGUENHEIM, and KRISHABER are nominated as members of the organising committee of a Congress of Laryngology to be held in Paris in September, 1882.

SURGEON-MAJOR SIR SAMUEL ROWE, K.C.M.G., Governor of the West African Settlements, has been appointed Governor of the Gold Coast Colony.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

SMALL-POX HOSPITALS.

Mr. N. C. Collier, the medical officer of health of the Fulham District of the metropolis, has addressed a letter to the local authority protesting against a proposition of the Metropolitan Asylums Board to increase the accommodation for small-pox patients in the Fulham hospital by 250 beds. Mr. Collier disavows any sympathy with the opinion that small-pox is distributed from a small-pox hospital by atmospheric infection. His experience does not appear to lend any support to this view of the question; but he entertains no doubt of the exceptional prevalence of the disease in the neighbourhood of hospitals (meaning the metropolitan we presume), and he is equally convinced of the causes of such prevalence. He attributes this prevalence to the unusual opportunities of the indirect communication of the contagion by the conveyance of patients to the hospital, through carelessness of the carriers, the friends accompanying them, and the flocking of both relatives and friends into the district of the hospital from infected centres. He writes of the impracticability of getting rules for preventing this indirect communication of infection observed by sub-officials and others engaged in the conveyance of patients; of the impossibility of controlling the contagion conveyed in the movements of persons in the infected houses, and which may even attach to the money passed across the bar and counter of the tavern and refreshment house. It is obvious that the larger the number of patients accumulated at one spot the greater must be the multiplication of the chances of disseminating the contagion of the disease in this fashion. The true way to minimise this danger he holds is for each parish to provide its own hospital, and he points out that this was the original intention of the promoters of the Sanitary Act, 1866. Mr. Collier is generally right in this reference. Our present huge hospitals are outcomes of the wondrously incoherent state of the local government of the metropolis. They were devised for poor-law purposes, irrespective of medico-sanitary requirements or of their relation to the public-health generally. But the sanitary authorities of the metropolis ignored as a rule their moral if not legal duties under the Sanitary Act of 1866, and so it has come to pass that the Metropolitan Asylums Board has had to act as both sanitary and poor-law authority in the matter of hospital accommodation in infectious diseases. If each metropolitan sanitary authority had carried out frankly and fully the intention of the Act of 1866, it is probable the metropolis would have escaped its present difficulties as to infectious hospital accommodation, and that a much greater control would have been exercised over the spread of small-pox.

THE HAMPSTEAD HOSPITAL.

Mr. Pearson Hill and the solicitors for the plaintiff in this case have taken exception in *The Times* to certain statements in Dr. Brewer's letter, which we published from that journal last week. Mr. Pearson Hill writes of the "parish of Hampstead" as if it were situated in space and not contiguous to the parish of St. Pancras, and as if a parochial boundary were proof against infection. His letter, however, is chiefly interesting as giving a summary of the plaintiff's evidence in this case as set before the jury, and it may be assumed was accepted by them. A greater condemnation of the anomalous position of the Metropolitan Asylums Board in the case could not well be conceived.

The city of Rochester and the town of Chatham having combined to form a joint Hospital Board, application is to be made to the Local Government Board for permission to borrow money with the view of purchasing two and a half acres of land whereon to build a hospital for infectious diseases.

A farmer has been fined £6 17*s*., including costs, at the Leicester County Police-court, for mixing the milk of certain cows affected with foot-and-mouth disease with other milk, and selling the mixed milk for human food, contrary to the Order in Council of the 9th July, 1879.

The *East London Observer* reports that the Local Government Board have decided to call for the resignation of the two medical officers in St. George's-in-the-East, a disagreement between whom led to an official inquiry, conducted by Dr. Bridges, to which we referred a short time ago.

One of the poor-law medical officers of Whitechapel is held to have vacated his appointment for having removed his residence outside the limits of the district for which he was appointed.

The Halsted Rural Sanitary Authority have adopted the recommendations of a committee of their body to establish three cottage hospitals for infectious diseases in their district.

We understand that it has been decided to remove the sanitary offices of the Port of London Sanitary Authority from Deptford to Greenwich.

The Local Government Board has issued an important series of model by-laws on Houses let in Lodgings, under the 90th section of the Public Health Act, 1875.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Influenced by the continuance of mild weather, the rate of English urban mortality is still exceptionally low for the time of year. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5883 births and 3109 deaths were registered last week. The births exceeded by 698, while the deaths were 166 below, the average weekly numbers during 1879. The deaths showed a decline of 199 from the number returned in the previous week. The annual death-rate, which had been equal to 18·6 and 23·7 in the two previous weeks, declined again last week to 21·3. The lowest death-rates in the twenty towns last week were 13·7 in Portsmouth, 15·9 in Leicester, 16·4 in Bradford, 18·1 in Birmingham, 18·3 in Oldham, and 18·5 in Sheffield. The rates in the other towns ranged upwards to 24·3 in Manchester, Liverpool, and Bristol, 24·8 in Leeds, and 25·4 in Sunderland. During the thirteen weeks of last quarter the death-rate in the twenty towns averaged only 21·5 per 1000, against 25·0 and 24·2 in the corresponding periods of 1878 and 1879.

The deaths referred to the seven principal zymotic diseases in the twenty towns, which had been 342 and 398 in the two preceding weeks, further rose last week to 401; they included 105 from scarlet fever, 87 from measles, and 39 from fever, principally enteric. The annual death-rate from these zymotic diseases averaged 2·7 per 1000 in the twenty towns; it ranged from 0·7 and 1·0 in Wolverhamptom and Sheffield, to 3·5 in Oldham and Sunderland, and 4·1 in Nottingham. Scarlet fever showed the largest proportional fatality in Sunderland, Norwich, Nottingham, Oldham, and Bristol; and whooping-cough in Nottingham, Portsmouth, Sunderland, and Leeds. The highest death-rates from fever occurred in Plymouth, Leicester, and Leeds. The 17 deaths referred to diphtheria in the twenty towns included 11 in London. Small-pox caused 38 more deaths in London and its suburban districts, and 2 in Birmingham; no fatal case of this disease was recorded in any of the eighteen other provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 440 in the ten preceding weeks, further rose to 447 on Saturday last. The number of new cases of small-pox admitted to these hospitals, which had been 65 and 146 in the two previous weeks, were 85 last week. On Saturday last 24 patients were under treatment in the Highgate Small-pox Hospital, being 4 less than the number at the end of each of the two preceding weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 290 and 353 in the two preceding weeks, further rose last week to 363; these were, however, no less than 132 below the corrected average number in the corresponding week of the last ten years; 232 were ascribed to bronchitis, and 85 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 5·1 per 1000 in London, corresponding with the rate from the same diseases in Liverpool.

In the twenty towns last week the causes of 83 deaths were not certified, either by a registered medical practitioner or by a coroner, being equal to 2·7 per cent. of the total deaths. The proportion of uncertified deaths was equal to 1·9 per cent. in London, and averaged 3·4 per cent. in the nineteen provincial towns. No uncertified deaths were registered either in Brighton, Portsmouth, Plymouth, Nottingham, or Newcastle-upon-Tyne; while their proportion was largest in Salford, Sheffield, and Leeds.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 25·9 per 1000 last week, against 20·8 and 22·5 in the two preceding weeks; this rate exceeded by no less than 4·6 per 1000 the average rate last week in the twenty large English towns. The rates in the eight Scotch towns ranged from 15·9 and 21·4 in Greenock and Perth, to 30·6 and 36·0 in Aberdeen and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 92 and 93 in the two preceding weeks, further rose to 105 last week, and were equal to an annual rate of 4·1 per 1000, against 2·7 in the twenty large English towns. In the eight Scotch towns the zymotic death-rate last week ranged from 2·9 and 3·2 in Dundee and Greenock, to 6·1 and 8·5 in Leith and Paisley; no deaths from any of these zymotic diseases were registered either in Aberdeen or Perth. The fatal cases of scarlet fever in the eight towns, which had been 29 and 30 in the two preceding weeks, declined to 27 last week, of which 12 occurred in Glasgow, 9 in Edinburgh, and 5 in Leith. The 29 deaths from whooping-cough showed a further increase upon recent weekly numbers, and included 13 in Glasgow, 7 in Edinburgh, and 5 in Dundee. The 20 fatal cases of diphtheria also showed an increase; no less than 14 were returned in Glasgow. The 7 deaths from "fever" corresponded with the number in the previous week, and included 4 in Glasgow, 2 in Edinburgh, and 1 in Paisley. The annual death-rate from acute diseases of the lungs (bronchitis, pneumonia, and pleurisy) was equal to 6·3 per 1000 last week in the eight Scotch towns, against 4·6 in London; the increased fatality of these diseases in the Scotch towns was confined to Glasgow, but their death-rate was also exceedingly high in Aberdeen.

HEALTH OF DUBLIN.

The registered mortality in Dublin again showed a marked excess last week. The annual death-rate from all causes in the city, which had been equal to 27·0 and 35·8 in the two preceding weeks, was last week 31·8; and the death-rate during the thirteen weeks of last quarter averaged no less than 32·6 per 1000, against 20·9 in London and 21·8 in Edinburgh. The 203 deaths in Dublin last week showed, however, a decline of thirteen from those returned in the previous week; they included 28, or rather less than 14 per cent., which were referred to the seven principal zymotic diseases, showing an increase of one upon the number in the previous week. Of these 28 zymotic deaths, 13 resulted from fever (including typhus, enteric, and simple), 7 from scarlet fever, 3 from whooping-cough, 2 from diarrhœa, and one each from small-pox, measles, and diphtheria. The annual death-rate from these zymotic diseases was equal to 4·4 in Dublin, against 3·0 in London and 4·9 in Edinburgh. The deaths referred to fever in Dublin, which had been 7, 8, and 10 in the three preceding weeks, further rose to 13 last week, and were equal to a rate of mortality nearly eight times as high as the average rate from the same cause in the twenty large English towns. Fatal cases both of scarlet fever and whooping-cough in Dublin were less numerous than in the preceding week. The deaths both of infants and of elderly persons showed an increase upon recent weekly numbers.

PROGRESS IN REGISTRATION.

Ever since the Public Health Act of 1872 mapped out the whole of England and Wales into urban and rural sanitary districts, and provided each district with an authority which is responsible for its health condition and government, an increasing demand has arisen for trustworthy vital statistics relating to these sanitary districts. The registration system, however, which had for thirty-five years been accustomed to deal only with Poor-law unions or districts and registration sub-districts, did not kindly lend itself for the provision of the required statistics of sanitary districts. The boundaries of urban sanitary districts seldom correspond with those of parishes, townships, or registration sub-districts, hence it was next to impossible for medical officers of health, even if provided with copies of the Birth and Death Registers, to compile correct statistics for their district. Not only were the urban and rural portions of a divided parish undistinguished in the registers, but in the registration of deaths in public institutions (mainly workhouses, hospitals, and lunatic asylums), the previous residence of deceased inmates was not recorded. It is satisfactory to hear that from the beginning of this year both these defects in our registration system have been removed. Registrars have been instructed to distinguish in each case whether the birth or death occurred in an urban or sanitary district, and so to describe the place of birth or death in the register, that the entry may be referred to the proper sanitary district. Instructions have also been issued by the Registrar-General, directing that in future, when registering deaths in public institutions, the registrars shall ascertain and insert in the register the previous residence of the deceased inmates. These two instructions, if intelligently carried out by registrars, will most materially assist medical officers in their statistical duties, and may, it is to be hoped, pave the way in time for the publication of official vital statistics for sanitary as well as, if not instead of, registration districts, which consist for the most part of an arbitrary aggregation of parishes and places, fixed more than forty years ago mainly for poor-law purposes. At present the only urban sanitary districts for which the Registrar-General publishes accurate statistics are the twenty largest English towns, and it cannot be doubted that much good would result from the publication of uniform and trustworthy statistics for a far larger list of urban sanitary districts. This will now become possible, in consequence of the before-mentioned improvements in our Birth and Death Registers.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DUBLIN SANITARY ASSOCIATION.

The eighth annual meeting of this Association was held at the Molesworth Hall, Dublin, on the 5th inst. The annual report referred to the accurate as well as graphic description given by the Royal Commissioners of the tenement houses in Dublin, and made suggestions for periodical analyses of the Vartry water; the prevention of slaughter-house nuisances; the provision of public baths and washhouses for the working classes, and the inspection and surveillance of public laundries. Dr. Johnston, president of the College of Physicians, in moving the adoption of the report stated that both the College of Physicians and College of Surgeons were entirely in accord with the movement promoted by that Association; and they were preparing a report in reference to the death-rate of the city. They fully believed that the high death-rate of the city was owing to the state of the tenement houses. They should be closely inspected, and an officer should also be appointed to investigate the cause of sickness in the tenement localities. Mr. C. H. Meldon, M.P., remarked that the Association had done admirable service in educating the public mind on sanitary subjects; but they must go further than they had yet done, and educate the minds of the lower classes on these topics, otherwise it would be impossible to carry out sanitary laws. A source of great danger was the bad condition of the connecting sewers in many of the very best houses in the city. There ought to be an inspection of those sewers, and he also concurred in the recommendation that public laundries should be registered and kept in proper condition. The Recorder of Dublin moved a resolution expressing the satisfaction of the meeting with the recent inquiry by the Royal Sanitary Commission, as being of so searching and comprehensive a character, and trusting that the recommendations of the Commission would be energetically carried into effect by the sanitary authorities.

OUTBREAK OF FEVER AT TANDRAGEE.

An epidemic of fever has recently taken place at Tandragee, a town in Armagh, with a population of some 1500 persons. It is reported that about 100 of these have been attacked, but the affection does not seem to be of a very malignant nature, as but ten or eleven persons have died from the epidemic during the past three weeks; no death has been recorded this week up to Tuesday last. It is said that no fatal cases have occurred where the patient was attended by a medical practitioner, and strict attention paid to sanitary regulations. The cause of the outbreak, which is probably a form of typhoid fever, appears to be due to contaminated water from one of the pumps which supply the town. The village schools have remained closed since the Christmas vacation.

UNHEALTHY INDUSTRIES.

Our contemporary *The Queen* is, we are glad to see, giving its readers a very able series of articles on the "Health Aspects of Women's Industries." Hygienic knowledge, to be of any real use, must be popularised, and any effort to make the industrial classes, or those who are brought in contact with them (and probably no class has better opportunities of disseminating useful knowledge than those readers of *The Queen* who practise charity as well as fashion), really acquainted with the evils and dangers to health which we encounter in our daily life is one to be encouraged; and we trust that the editor of the "Ladies' Newspaper" will continue the good work upon which he is engaged.

YELLOW FEVER.

Yellow fever has been more or less prevalent among the French garrison at St. Louis, Senegal, said to have originated from the overcrowding of the troop-ships conveying the reliefs to the garrison. Seventeen deaths were recorded between Nov. 20th and Dec. 2nd, 1880, and on the latter date a civilian was attacked, and died.

Mr. Sergeant, the medical officer of health for Bolton, has been lecturing publicly in that town on the avoidance of disease. An excellent lecture now reported is devoted to personal hygiene, and we trust it will be presently followed by one on a public hygiene. Lectures of this class are admirably adapted to instruct the hearers, and secure the willing co-operation of citizens in the difficult duties which a medical officer of health and his local authority have to perform in ralation to the public health.

An order has been issued by the Privy Council, under the Contagious Diseases (Animals) Act, 1878, setting forth the regulations to be followed in localities (areas) infected with foot-and-mouth disease.

THE SERVICES.

THE TRANSVAAL WAR.

In addition to the reinforcement of medical officers for service at the Cape, which we announced last week, the War Office has decided to send out a full Bearer Company of the Army Hospital Corps under the command of Surgeon-Major William Johnston. The company will consist of 136 non-commissioned officers and men of the Army Hospital Corps, with the following officers:—Surgeon-Major Thomas Faris, M.B., second in command; Surgeons W. C. Milward, Alfred Peterkin, P. B. Conolly, H. F. Babington, M.B., W. H. Bracken, M.D., and W. Dugdale. Captain of Orderlies James Gordon, Lieutenants of Orderlies W. Pike and H. S. Webb are attached for duty. A detachment of the Army Service Corps, consisting of one officer and forty non-commissioned officers and men, will join the company at Aldershot for transport duty prior to embarkation. The Bearer Company will, we believe, go out completely equipped, taking out ambulances, surgery waggons, stretchers, cacolets, and litters, the latter for conveying wounded over mountainous roads, and with all the latest improvements and appliances for the special work of removing wounded from the field, dressing their injuries, and conveying them to the field hospitals. Surgeon-Major Johnston, who has been selected by the Director-General for the command, has recently returned from a tour of service in South Africa, and was present at the storming of Seccocoeni's stronghold in 1879, where the Bearer Company under Surgeon-Major Hector did excellent service.

Brigade-Surgeon Edward M. Sinclair, M.D., has been ordered to the Cape for immediate service in the Transvaal.

Deputy Surgeon-General Thomas William Fox, M.D., has been appointed Principal Medical Officer of the Chatham District, in succession to Surgeon-General Henry Kendall, M.D., who retires on half pay.

Surgeon-Major David Woods, half-pay Medical Department, has been permitted to commute his half-pay.

SCOTS GUARDS.—Surgeon William Campbell, M.B., from the Medical Department, to be Surgeon; Surgeon G. S. Robinson, from the Medical Department, to be Surgeon; Surgeon Robert F. Cumming, from the Medical Department, to be Surgeon.

ROYAL NAVAL ARTILLERY VOLUNTEERS (Liverpool Brigade).—The following appointments have been made:—Alfred Charles Edward Harris to be Surgeon; Peter Murray Braidwood, M.D., to be Honorary Surgeon.

MEDICAL EDUCATION.

To the Editor of THE LANCET.

SIR,—The perusal of your leader on Medical Education induces me to offer a few remarks on this subject, and I will confine what I have to say to one point, and that is the question of apprenticeship as the commencement of a medical career. When, in 1872, I had the honour of giving the introductory lecture at the Middlesex Hospital, I ventured to express my own doubts as to whether the abolition of the old system of apprenticeship had been an advantageous move in the cause of medical education. Since the date just named, my opportunities of observation among students when in course of training by lectures and when under examination have increased much, and certainly the conviction is now strong in my mind that the abolition of apprenticeship was a great mistake, and a move that was much to the disadvantage of the medical student. A young man goes from school to live with a medical practitioner, and there he learns to compound the medicines which his master prescribes in his book when he comes in from his rounds. He sees how the mixtures look when they are made, and if they are clear and pleasing to the eye, if not to the palate, of the patient; and while gaining knowledge on these points, he soon becomes ready at reading and writing prescriptions—matters in which the knowledge of even the advanced students of the present day is often strangely deficient.

Not to mention the treatment of small surgical cases that come at all times into the surgery, whereby manual dexterity and tact are early acquired and developed, the apprentice enjoys the opportunity of going out with the assistant to visit patients at their own homes, and so learns to speak with wisdom and judgment to those who are sick, so acquiring "the mystery of practice"; and while thus employed he finds out pretty soon, and in good time, how he really likes the actual practice of the profession; and if he does not take kindly to it he can withdraw and turn to some other way of getting his living, for none are to be so sincerely pitied as those who have been led to seek their bread by the practice of physic, while they have an innate loathing of their art. There can hardly be even tolerable success without might or earnestness; mind must be thrown into the work, and "there cannot be might or earnestness—of the best sort—in an uncongenial enterprise" (THE LANCET, p. 65, Jan. 8th, 1881).—Yours, &c.,

JOHN C. THOROWGOOD, M.D., F.R.C.P.

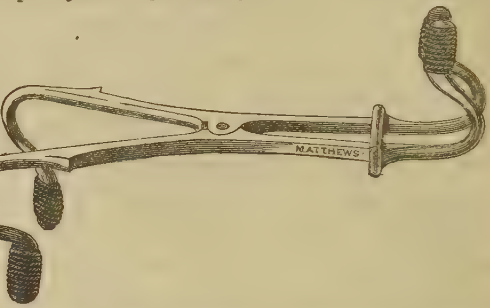
Welbeck-street, W., January, 1881.

THE NEW FORM OF GAG.

To the Editor of THE LANCET.

SIR,—With reference to Mr. T. Smith's letter on the above in your issue of last week, I wish to state, in fairness to Messrs. Matthews, that they were the first, about three years ago, to construct at my suggestion the double-ended gag *with the sliding ring-catch*, which Mr. Smith erroneously speaks of as an ingenious adaptation of Messrs. Mayer and Meltzer. In fact, it was at the request of Mr. Mayer that I lately sent him my gag to copy.

The addition of the tongue-plate, as suggested by Mr. Smith, will, in my opinion, be no improvement, as one of the great features of the gag (as shown in the illustration) is its simplicity and adjustability.



After considerable experience in operations about the mouth, where an anæsthetic is used, I have come to the conclusion that the tongue should be left perfectly free, and only occasionally depressed with a suitable spatula when dealing with parts which its presence obscures; for I have found that with the continuous pressure of a plate the tongue is always liable to bulge up behind it, and so impede or prevent respiration by pressing on the glottis, causing great danger to the patient and anxiety to the operator.

I am, Sir, yours obediently,

Welbeck-street, Jan. 10th, 1881. WILLIAM ROSE.

MAIN SEWER VENTILATION—CITY FILTH AND WATERCLOSETS.

To the Editor of THE LANCET.

SIR,—I suppose some people will say that an official ought not to waste his time by making any reply to adverse criticisms on his works and recommendations. This, no doubt, in a general way is true, but as there are special cases set forth in THE LANCET of the 8th inst., and replies to which may have general interest, I venture to break the rule.

At p. 70 of your last issue, under the heading "Sanitation in Leeds," the favourable returns as to the local health are commented upon. I beg to observe that in 1867, when making inquiry into rivers' pollution, I learned that the new sewers and drains were unventilated, and that the large main outlet sewer presented its open end unprotected for the wind to blow into, and so drive sewage gases, with increased force, to the upper portions of the town. There had been and were at the time many cases of fever throughout the town, but more especially in the new and better class of suburban houses, which had been drained to the new sewers. I obtained returns of the expenditure on these new sewers, and for the same period a return of the rate of local mortality; and I pointed out to the Chairman of the Works Committee that an increasing death-rate had followed closely the increasing main sewering and draining expenditure, and I put the question to him, "Do you think such result should be?" There was of course only one form of answer possible—namely, that the result ought to have been the other way. I then pointed out that the open-mouthed main sewer should be closed so as to allow sewage to flow out and prevent the wind driving in, that all the main sewers should be abundantly ventilated, and that house drains should be disconnected by external ventilation. These things have been done, and more, the local surveyor having gone a very wide step in advance, by untrapping all the street gullies, to the extent of some 20,000 in number, the aggregated area of the whole being about 3600 square feet. I do not know of any other town which has gone so far in main sewer ventilation. You give the results in your notice, as above quoted—namely, a local death-rate for the four weeks ending the 27th of November, 1880, not exceeding 19·9 per 1000, as against 25·6 in the corresponding period of 1879. There is no one thing connected with the main sewering and house draining so obstinately resisted as is main sewer ventilation. The engineers' inspectors, at their local inquiries for main sewering or sewers' extensions, stipulate, before promising to recommend sanction, that the sewers shall be fully and properly ventilated. The promise may be given, only to be entirely neglected, or most inefficiently carried out; and then, if there is defective workmanship in the sewer construction, in flushing, and, as a consequence, foul accumulations, the few small openings made at wide intervals apart become nuisances and are closed—so that main sewer ventilation ceases, excepting through the drains and into the connected houses, the results being malarious sickness. Half-informed men then, both at home and abroad, take up their parable and denounce main sewering, house draining, and waterclosets, as if these were mere inventions of the evil one to inflict sickness and misery on man. Let me repeat once again that house-drains which do not drain, and main sewers which do not sewer—that is, do not unceasingly transmit all sewage by an even and continuous flow to some common outlet—must not claim my parentage. The sewers and drains I recommend must have full, abundant, and free ventilation to the external air—every house to be so drained, ventilated, and connected with the main sewers, so as to be free from any possibility of scourge taint, as if standing isolated in the middle of a separate plot.—I remain, Sir, yours faithfully,

London, Jan. 11th, 1881. ROBERT RAWLINSON.

BOGUS DEGREES AT HOME.

To the Editor of THE LANCET.

SIR,—As the question of reform in medical education is coming more and more to the front, there are one or two questions which many who are interested in the subject would like to have answered.

It has been asserted that the Medical Corporations of Scotland have solved the whole problem. In view of this assertion, I ask—

(1) Is it true, as has been alleged, that the Fellowship of the Royal College of Surgeons of Edinburgh can be obtained *without examination*, upon the payment of the necessary fee?

(2) Is it a fact that the F.R.C.S. of Edinburgh is a sufficient qualification for the office of surgeon to any (or some) of the metropolitan hospitals?

(3) Can a candidate who has failed to obtain the double Edinburgh qualification (L.R.C.S., L.R.C.P.) obtain the L.R.C.P., or some similar licence, and then be straight away elected to the F.R.C.S.?

If these things indeed be true, then there is gross injustice and a glaring inequality between the Fellowship of the London College of Surgeons and that of the Edinburgh College. The F.R.C.S. Eng. requires an extended curriculum and a strict examination. If the Edinburgh F.R.C.S. can be bought, it is clearly a much lower title, while the public is under the belief that the two are of equal value. Well, if this be the solution that is satisfactory to the Scottish Corporations, it is certainly not so to those who, like myself, claim to be

A DISINTERESTED MEDICAL REFORMER.

Jan. 11th, 1881.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, Mr. P. A. Taylor again gave notice of his anti-vaccination resolution, which he subsequently put down for discussion a month hence. It is in the following terms: "That, in the present unsettled condition of medical opinion in regard to the safety of using ordinary humanised lymph, as also of the safety, effectiveness, and practicability of the use of animal vaccine, it is, in the opinion of this House, inexpedient and unjust to enforce Vaccination under penalties upon those who regard it as unadvisable or dangerous."

On Friday, Mr. Stansfeld reintroduced the Bill for the repeal of the Contagious Diseases Acts. The names on the back of the Bill are Mr. Stansfeld, Mr. W. Fowler, Mr. H. Fowler, and Mr. J. Cowen. Mr. O'Shaughnessy brought in a Bill further to facilitate the building, enlargement, and maintenance of reformatory institutions in Ireland. Mr. Hardcastle, in conjunction with Sir Trevor Lawrence and Dr. Farquharson, brought in a Bill to amend the Medical Act, 1858; and Mr. Gray, a Bill to provide for the better notification of infectious diseases in Ireland. Petitions were presented on behalf of Dr. C. A. Holcombe and Surgeon-Major T. G. Skardon for inquiry into their respective cases. A copy was presented of further correspondence respecting the manufacture of "oleomargarine" in the United States.

On Monday a return, ordered last August on the motion of Mr. Meldon, was presented of all medical officers of workhouses, &c., in Ireland who have resigned their offices and applied to their Boards of Guardians for superannuation. A return, ordered in the same month on the motion of Mr. Callan, of correspondence relative to the treatment of patients in Dr. Steevens's Hospital, was also presented. Mr. Dillwyn reintroduced his Bill to amend the laws relating to the custody and treatment of lunatics, and it was put down for second reading on Wednesday, May 25th. Mr. Errington gave notice that on Monday next he will ask the Vice-President of the Council whether he will agree to the appointment of a Select Committee to continue the inquiry commenced in 1878 into important questions of medical reform. Mr. Grantham asked the Secretary of State for India if he has inquired, in pursuance of his promise in August last, of the proper authorities in India, whether, by the report of a medical board dated September 5th, 1868, signed by Surgeon-Major Peskett, Surgeons Lowdell and Condon, and Assistant-Surgeon Walsh, at Nynee Tal, Capt. Chatterton was not recommended to take twelve months' leave of absence for the purpose of returning to England to undergo an operation—viz., the division of the left tendo Achillis—on the ground that it was not safe to perform the operation in India. Whether Surgeon-Major Powell, acting as garrison surgeon in Fort William, Calcutta, did not afterwards, in April, 1869, confirm the above recommendation on the same ground. Whether the only report on which the despatch of January 5th, 1869, ordering the compulsory retirement of Captain Chatterton, was founded, and which practically alleged that he was shamming, was not that made in Nov. or December, 1868, by Assistant-Surgeon M'Dermott, who was shortly afterwards removed from the medical charge of that and other cases previously under his care. And how it was that Captain Chatterton was dismissed the army in April, 1869, on the report of an assistant-surgeon, when Captain Chatterton was acting on the reports of more eminent surgeons made both before and after the report of the assistant-surgeon. The Marquis of Hartington briefly replied that he had caused inquiry to be made into the case, and was waiting the result. Mr. Parnell put a series of questions as to the treatment of certain members of the Land League in Tralee gaol. Mr. Forster postponed a detailed reply, but stated that instructions had been sent to Dublin, in reply to a complaint by the prisoners, directing that their personal requirements should be attended to.

On Tuesday, petitions for inquiry into the Indian Medical Service were presented on behalf of Matthew Moriarty and William Courtney. Mr. Errington gave notice of a Bill to alter the qualifications required for holding certain medical appointments.

On Wednesday a further petition *re* the Indian Medical Service was presented from James R. Jackson.

On Thursday, Mr. Dwyer Gray, ex-Lord Mayor of Dublin, questioned the Chief Secretary for Ireland as to an outbreak of fever at Tandragee. Mr. Forster said he was sorry there had been an outbreak of fever at Tandragee. It was caused, not by the importation of foreign flax, but by the impurity of water obtained from a well. The Local Government Board were doing all they could to prevent the spread of the fever. The well had been closed, a second medical officer had been appointed in the district, and one of the medical inspectors of the Board had been specially sent to Tandragee. The latest report said the disease was abating, and that the number of deaths up to Tuesday was seven, not eleven.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council, held on Thursday last, after the transaction of the ordinary routine business, the Committee on Preliminary Examinations, appointed on Dec. 9th, 1880 (see THE LANCET, Dec. 11th, 1880), presented their first report, dated January 10th. They recommended that the preliminary examinations for the diplomas of Member and Fellow, at present conducted by the College of Preceptors under the authority of the Council, should cease from and after the 31st of December, 1881, and that in communicating the decision to the General Medical Council, it should be intimated that the giving up of the College Preliminary Examinations renders it in the highest degree desirable that the General Medical Council should, so far as may be possible, require that examinations recognised in lieu of the College examination should be held at such times and places as may best suit the convenience of candidates who desire to enter the medical profession. With regard to the regulations relating to the several preliminary examinations recognised by the College, whether for the Fellowship or Membership, the committee recommended (1) that a certificate of registration by the General Medical Council shall entitle a candidate to commence his professional education at any time after the date of registration; (2) that the Council reserve to themselves the right of determining the conditions of admission to examination for the diploma of the College in the case of any colonial, Indian, or foreign student not registered by the General Medical Council; (3) that, in future, candidates for the diploma of Fellow be not required to undergo any preliminary examination beyond that required for the diploma of Member, and (4) that the regulations for obtaining the diplomas of Member and Fellow of the College be altered in accordance with these resolutions. The Committee has reserved to a further report the subjects contained in Dr. Haldane's communication respecting the desirability of candidates for the medical profession being required, before they enter on the purely medical curriculum, to have been instructed and examined in the rudiments of natural science, physical, chemical, and biological (see THE LANCET, Dec. 11th, 1880).

The Committee on the necessary arrangements for the institution of additional examinations for the diplomas of Member and Fellow, appointed on Nov. 13th, 1879 (see THE LANCET, Nov. 15, 1879), presented their second report, dated Jan. 6th, 1881. In their first report, dated May 10th, 1880 (see THE LANCET, May 15th, 1880), the Committee recommended that notice should be given to the several medical authorities concerned in "the conjoint scheme" of the intention of the College to withdraw from that scheme. This recommendation was adopted on June 10th in a modified form—namely, that "in view of the uncertainty which prevails as to the compulsory establishment of a conjoint scheme in each division of the united kingdom, the Council give notice to the several medical authorities in England, of their intention, whether alone or in conjunction with other bodies, to make arrangements for the institution of a complete examination to be passed by all candidates for the diplomas of Member and Fellow of the College." In their second (present) report the committee state that at their request the president addressed a letter to the President of the Royal College of Physicians of London, wishing him and other delegates from his College to meet the committee and confer on the practicability of making arrangements for a joint examination for qualification to practise medicine, surgery, and midwifery. That the invitation was declined on the ground that the Royal College of Physicians, being bound by the terms of the conjoint scheme, dated the 1st of May, 1877, could not take part in the formation of any other examining board until after the expiration of five years from the 1st of October, 1877, the shortest time fixed by the scheme for its duration; and that the President, on behalf of the Committee, pointed out to the President of the Royal College of Physicians that the interpretation thus put upon Section 12 of the scheme was at variance with that held by the College—namely, that the said section is binding on the several medical authorities only on condition that the conjoint scheme has come into actual force. To this objection the President of the College of Physicians has not yet replied. Having failed in their endeavours to bring about a conference with the Royal College of Physicians, the Committee entered without further delay into the consideration of the arrangements for the institution of further examinations for the Membership and Fellowship. The Committee has reserved any recommendations on the institution of examinations in chemistry, materia medica, medical botany, and pharmacy; but in regard to medicine and midwifery the Committee recommended the following resolutions for adoption:—1. That there be four instead of two examiners in medicine. 2. That the examination in medicine, both written and *vivâ voce*, be extended, and do include the examination of patients. 3. That on and after Jan. 1st, 1882, every candidate for the final Membership or Fellowship examination be required to pass an examination in midwifery, unless he shall possess a recognised qualification in midwifery, or, before obtaining the diploma, shall produce a certificate of having passed the necessary examinations entitling him to a recognised qualification in midwifery. 4. That there be two examiners in midwifery. 5. That the examination in midwifery be partly written and partly *vivâ voce*. 6. That candidates, having passed the examination in midwifery for the Membership, or any examination recognised as equivalent thereto, be not required to undergo any further examination in midwifery for the Fellowship. 7. A candidate for the Membership or Fellowship to be exempted from the necessity of passing an examination in medicine or midwifery—(*a*) if he possess any degree, diploma, or licence in medicine or midwifery, registrable under the Medical Act of 1858, as a legal qualification to practise in medicine or midwifery, as the case may be; (*b*) or any degree, diploma, or licence in medicine or midwifery, of a Colonial, Indian, or foreign university, which the Council may, on special application, consider to be sufficient.

The reports of both committees were adopted, and it was resolved that the recommendations contained therein should take effect at once, without waiting for the confirmation of the minutes.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners during the week.:—

J. England Walker and William Atkinson, University College; James Darbyshire and Benjamin Blakemore, Manchester; W. A. Winship, Newcastle-on Tyne; Henry Knowles, Leeds; Percy H. White, Edinburgh; James Cox, Melbourne, Australia; Herbert Ley, Walter F. Mitchell, and Bowen S. Mends, St. Bartholomew's Hospital; George Stoker, Joseph R. Lock, and Herbert C. Hodges, St. Thomas's Hospital; David P. Key, H. H. W. Button, and Thomas B. Winter, Guy's Hospital; Arthur W. C. Peskett, and Adolphus J. Richardson, London Hospital; Ithel P. Llewelyn, King's College; Reginal L. Huzzey, Charing-cross Hospital; James H. Daniel, John E. London, Thomas A. Guinness, Robert Cheyne, William S. Hayman, Samuel Camps, Samuel C. Philson, Charles H. Piesse, and Meryon S. Wilson, King's College; George F. Phillpot, Francis J. Lea, Frederick W. Cock, Hedley V. Drew, Donald S. Gunn, and Charles J. Lumpkin, University College; Robert Hall Wilkinson, Gaskion R. M. Wright, Philip T. Richards, William T. Partridge, Rhys S. Jones, William H. Clark, Francis Dean, St. Bartholomew's Hospital; Edgar Wakelam, Augustus L. Paliologus, Wilfred Howard, and Ernest D. Minter, Guy's Hospital; George Hessenaur, London Hospital; Charles H. Thompson, Dublin and St. Thomas's Hospital; Arthur J. Barnard, St. George's Hospital; Henry J. C. Godfrey, John A. Soothern, John E. Dunn, and Penn Furnivall, St. Thomas's Hospital.

Of the 146 candidates examined 66 were referred for three and seven candidates for six months further anatomical and physiological study.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Jan. 6th:—

Clarke, Fincastle Geo. Barlow, Upper Norwood.
Hodgson, John, Oldham, Lancashire.
Knaggs, Henry Valentine, Camden-road.
Prendergast, Joseph Moran, Melbourne, Australia.
Ross, Ronald, Southampton.

The following gentlemen also on Dec. 30th passed their Primary Professional Examination:—

John Hoole, St. Bartholomew's Hospital; Fredk. Hamilton Kenny, London Hospital.

[The address of Mr. Wordley, in the list published on Jan. 1st, should have been printed "Great Suffolk-street."]

BEQUESTS AND DONATIONS TO MEDICAL CHARITIES. Mr. J. F. Stanford, F.R.S., late of North Bank, Regent's Park, bequeathed £25,000 to St. Mary's Hospital, to build a new wing to bear the name of his mother, Mrs. Mary Stanford. The Gloucester Infirmary becomes entitled to £500 by the will of the late Mr. W. J. Holt, of Gorphwysfa, Carnarvonshire. As one of the residuary legatees of the late Dr. Scott, of Perth, the County and City of Perth has received £3603 9*s.* William Denis Browne has given £100 to the Meath Hospital, Dublin; and the Adelaide Hospital has received £100 under the will of the late Misses Adams. Mr. William Tattersall has given £1000 to the Blackburn and East Lancashire Infirmary, in augmentation of the endowment fund.

DEVONSHIRE HOSPITAL, BUXTON.—Dr. Robertson, Chairman of the Board of Trustees and Committee of Management of this charity, is able to give a favourable report of the institution, to which there has now been added a Samaritan Fund. A good feature in the administration of the charity is the issue of postal cards to in-patients on leaving the hospital, to be filled up and returned six weeks after discharge, and on which is to be stated the result of the treatment received. During the seven years this arrangement has been in existence 7695 of these cards have been returned; by these, 5579 patients are reported as improved, 2077 as no better, and 39 as having died.

THE Baxter Physical Science Scholarship of £116, conferred by the University of Edinburgh on the most eminent B.Sc. who has taken his degree during the present or the preceding year, has been awarded to Mr. D. Orme Masson, lecturer on Chemistry at University College, Bristol, who is prevented from accepting it in consequence of holding his present appointment.

UNIVERSITY OF DUBLIN.—The Board of Trinity College have granted the degree of Bachelor in Medicine (without fees) to Mr. John Charles Martin, for distinguished success in having obtained double first place at the recent examinations for medical and surgical degrees.

THE salary of the medical superintendent of the Three Counties Lunatic Asylum has been increased from £600 to £700, and that of the senior assistant medical officer £10 a year, up to £200.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund, Dr. H. J. Domville, C.B., Inspector-General, in the chair, the sum of £60 was distributed among the several applicants.

THE Hospital Sunday collection in Liverpool, made on the 9th inst., has realised, so far as is at present ascertained, a sum of £2871, against £2819 last year. At Aberdeen the collection amounted to £432 18*s.* 10*d.*

THE magistrates of Cornwall have sanctioned the expenditure of £20,000 for the enlargement of the County Lunatic Asylum, so as to provide accommodation for 150 additional pauper lunatics.

THE Duke of Connaught has consented to preside at the anniversary festival on behalf of the Hospital for Sick Children, to be held at Willis's Rooms on March 16th.

THE Local Government Board have made a first class grant of £10 13*s.* for efficient vaccination to Mr. Wm. Milligan of Wirksworth.

QUEEN'S COLLEGE, BELFAST.—Prof. Nesbitt has been appointed librarian to this institution.

DR. THOMAS O'SULLIVAN has been elected Lord Mayor of Limerick.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

BRITTON, T., M.D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Halifax Rural and Combined Sanitary Districts.

BUXTON, T., M.R.C.S.E., has been appointed Medical Officer for the Kingsbury and Fazeley Districts of the Tamworth Union.

COLLEDGE, L. R., L.R.C.P., M.R.C.S.E., has been appointed Assistant Surgical Registrar to St. George's Hospital.

DAWSON, W., M.B., M.R.C.S.E., has been appointed Medical and Surgical Registrar to the Victoria Hospital for Children, vice Dr. Beckingsale, resigned.

DUNSMURE, J., M.D., F.R.C.S.Ed., has been appointed Medical Officer to the Pensioners of Trinity College Hospital, Edinburgh.

EVANS, E. P., L.R.C.P.Ed., has been appointed Medical Officer for the Mountain Ash District of the Pontypridd Union.

HALL, R. S., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Ince-in-Makerfield Urban Sanitary District.

HANNAH, N., L.R.C.P.Ed., L.F.P.S.G., has been reappointed Medical Officer of Health for the Ashton-in-Makerfield Urban Sanitary District.

HASLAM, G. J., M.D., M.R.C.S.E., has been appointed District Surgeon to the Salford and Pendleton Royal Hospital, vice J. Newton, promoted to House-Surgeon.

HERMAN, G. E., M.B., M.R.C.P.L., F.R.C.S.E., has been appointed Physician to the Eastern Division of the Royal Maternity Charity, vice Roper, resigned.

HOLDEN, L., F.R.C.S.E., has been appointed Consulting Surgeon to St. Bartholomew's Hospital.

ILLINGWORTH, C. R., M.B., C.M., M.R.C.S.E., has been appointed Medical Officer for the Rishton and Clayton-le-Moors Districts of the Blackburn Union, vice Pilkington.

LEAHY, A. W. D., M.R.C.S.E., L.S.A.L., has been appointed Medical Registrar at Charing-cross Hospital.

MAHON, G. A. D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Eighth District of the Newport Pagnell Union.

MILNES, G. H., M.R.C.S.E., has been appointed Assistant House-Physician to St. George's Hospital.

NEWTON, J., M.R.C.S.E., has been appointed House-Surgeon to the Salford and Pendleton Royal Hospital, vice D. T. Evans, M.R.C.S.E., L.S.A.L., resigned.

PRICE, J. L., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Standish-with-Langtree Urban Sanitary District.

SHIVES, J., M.D., L.R.C.S.Ed., has been appointed Medical Officer of Health to the Liversedge Urban Sanitary Authority, vice Sykes.

SMITH, R., M.D., C.M., M.R.C.P.L., has been appointed an Assistant-Physician to Charing-cross Hospital.

Births, Marriages, and Deaths.

BIRTHS.

CAREY.—On the 8th inst., the wife of Richard John Carey, M.A. Camb., Medical Officer of Canning-town, E., of a daughter.

COTTON.—On the 9th inst., at Sloane-street, S.W., the wife of Holland J. Cotton, M.D., of a son.

JONES.—On the 4th inst., at Chesham-place, the wife of T. Ridge Jones, M.D., of a daughter.

KENDALL.—On the 28th ult., the wife of Surgeon-General Henry Kendall, M.D., Principal Medical Officer, Chatham District, of a son, who survived his birth only a few minutes.

MARRIAGES.

BEDFORD—DRAKEFORD.—On the 29th ult., at St. Bartholomew's Church, Sydenham, Walter George Augustus Bedford, M.B., M.R.C.S.E., of the Army Medical Department, youngest son of the late Vice-Admiral G. A. Bedford, of The Elms, Sydenham-hill, to Adelaide, eldest daughter of the Rev. D. J. Drakeford, M.A., of Elm-grove, Sydenham.

CARMICHAEL—BRIDGET-HAWES.—On the 29th ult., at St. Luke's, Redcliffe-square, Daniel Macrae Carmichael, M.B., M.C., of Portree, N.B., to Hannah Sarah, daughter of the late Mrs. Bridget-Hawes, of Priory-grove, South Kensington.

FROST—ANDERSON.—On the 8th inst., at St. Michael and All Angels', Paddington, William Adams Frost, F.R.C.S., second son of C. M. Frost, Esq., of Ladbroke-square, to Maria Deane, eldest daughter of W. J. Anderson, of Sans Souci, Cape Colony, and Westbourne-terrace, W.

HADDEN—LESLIE.—On the 11th inst., at the Parish Church, Alton, Hants, Martin Lindsay Hadden, son of the late James F. Hadden, Esq., of Union-grove, Aberdeen, to Alice, second daughter of Louis Leslie, M.D., of Amery House, Alton.

DEATHS.

ALCOCK.—On the 23rd ult., at his residence, Catherine-street, Waterford, Daniel Robert Alcock, Staff-Surgeon R.N. (retired), aged 43.

BAIN.—On the 8th inst., at "Balmoral," Bournemouth, Benjamin Bain, L.R.C.S.Ed., L.R.C.P.Ed., late of Birtley, co. Durham, aged 37.

BARFOOT.—On the 5th inst., at Freshwater Villa, Cadogan-road, Surbiton, Edward Wade Barfoot, M.R.C.S.E., in his 74th year.

DOWNING.—On the 7th inst., at Franklin-road, Brighton, the residence of his sister, Edward Hugh Downing, M.R.C.S.E., of Deptford, Kent, in the 32nd year of his age.

KNOTT.—On the 8th inst., at his residence, Harwich, and without any previous illness, William Knott, M.R.C.S.E., Half-pay, 6th (Inniskilling) Dragoons, aged 88.

WIGG.—On the 22nd ult., at King's Lynn, Norfolk, Eleanor Hart, wife of Thomas Carter Wigg, M.D., formerly of Ballarat, Victoria. (Australian papers please copy.)

WOOLLEY.—On the 31st ult., at Kent Cottage, Old Kent-road, S.E., Samuel Poole Woolley, M.B., M.R.C.S.E., &c., aged 36.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

Monday, Jan. 17.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

St. Mark's Hospital.—Operations, 2 p.m.; on Tuesday, 9 a.m.

Medical Society of London.—8½ p.m. Mr. John Brunton, "On a case of Nævus of the Scalp successfully treated by Sodium Ethylate"; Dr. B. W. Richardson, "On Sodium Ethylate in the treatment of Nævi and other forms of disease, with remarks on Potassium Ethylate."

Tuesday, Jan. 18.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Pathological Society of London.—8½ p.m. The following specimens will be shown:—Recurrent Multiple Sarcoma; Localised Scleroderma (living specimen); Acute Myositis; Abscess of Liver following Dysentery; Cirrhosis of Liver in a Child; Cystic Degeneration of the Breast; Two cases of Tricuspid Stenosis; Case of Chloasma (living specimen); Perforation of Septum Ventriculorum and Thrombosis of Pulmonary Artery (card); Thrombosis of Innominate Vein; Congenital Sacral Tumour (card); &c.

Royal Institution.—3 p.m. Professor Edward A. Schäfer, F.R.S., Fullerian Professor of Physiology, R.I., "On the Blood."

Wednesday, Jan. 19.

National Orthopædic Hospital.—Operations, 10 a.m.

Middlesex Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital. — Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ p.m., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ p.m.

King's College Hospital. — Operations, 2 p.m., and on Saturday at 1 p.m.

London Hospital.—Operations, 2 p.m., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital. — Operations, 2 p.m., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children. — Operations 2½ p.m.

Society for the Encouragement of Arts, Manufactures, and Commerce.—8 p.m. Mr. A. G. Lock, "On Causes of Success and Failure in Modern Gold-mining."

Thursday, Jan. 20.

St. George's Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital.—1½ p.m. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital. — Operations, 2 p.m., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 p.m.

North-West London Hospital.—Operations, 2½ p.m.

Royal Institution.—3 p.m. Mr. Francis Hueffer, "On the Troubadours."

Friday, Jan. 21.

St. George's Hospital.—Ophthalmic Operations, 1½ p.m.

St. Thomas's Hospital.—Ophthalmic Operations, 2 p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Royal Institution.—8 p.m. Mr. Warren De La Rue, "On the Phenomena of the Electric Discharge with 14,400 Chloride of Silver Cells."

Saturday, Jan. 22.

Royal Free Hospital.—Operations, 2 p.m.

Royal Institution.—3 p.m. Mr. Sidney Colvin, M.A., "On The Amazons: A Chapter in the Study of Greek Art and Mythology."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Venous Pulsation.

At a meeting of the Medical Society of the College of Physicians in Ireland last week the Vice President of the College (Dr. W. G. Smith) detailed a case of aortic and mitral valve disease in which a venous pulsation could be detected on the back of the hands. It occurred in a man aged thirty-seven, who had suffered from two attacks of rheumatic fever, and for about nine days, and until shortly before death, a venous pulsation on the back of both hands, and passing for three inches up the forearms, was apparent. There was an appreciable interval between the arterial and venous pulsation, and pressure stopped the pulsation between the part compressed and the heart, the venous wave being in the direction of the blood-stream. It was suggested that the pulsation was derived from the left side of the heart, being transmitted from the arterial system into the venous circulation through the capillaries. The heart weighed on removal 1 lb. 5½ oz.

SILICA AS AN ANODYNE IN CANCER.

To the Editor of The Lancet.

Sir,—At the present time, when new remedies are being anxiously sought in the hope of finding one that will alleviate the intense pain experienced by those afflicted with cancer, I think it worth while to submit to the notice of your readers the following particulars connected with a case now under my charge.

On November 5th, 1880, I was asked to see Mrs. S——, residing in this neighbourhood, and, by examination, discovered that she had malignant disease of the cervix uteri, from which she had been suffering to her own knowledge for the last six months.

Her condition was one of great mental distress and bodily agony. She had had no sleep of more than ten minutes' duration for three weeks before I saw her, and was never free from pain when awake. She described the pain "as if numbers of lancets were being stuck into the lower part of the body, and as if hooks were inserted into her hips, and then torn out; and as if the bottom of her back were being cut off from the rest of her body."

I ordered one grain of silica in the form of "silicon lozenges" three times a day, and to continue taking an anodyne mixture at night, which had previously been prescribed by another medical gentleman, to whom she could go no longer in consequence of increasing weakness.

On Nov. 8th I saw her again, and I found that she had suffered much less pain, and had slept on the night of the 7th for twenty minutes at a time. As the mixture produced constipation, I ordered her to discontinue its use, and to continue the lozenges.

On Nov. 11th I saw her for the third time, and found her moving about the house, comparatively cheerful, able to read with enjoyment, and that the pain had become, in her own words, "quite bearable," and was not constant. Sleep also had returned to a considerable degree, although taking no anodyne but the silicon lozenges, the intervals between waking being less frequent.

On Nov. 20th I visited her again, and found her more cheerful than before, and, as far as pain was concerned, she informed me "that she had no real pain, only an uncomfortable feeling about the lower part of the body." The lozenges, too, seemed to soothe her, and she could now sleep soundly for one hour, and believes she would sleep for longer periods but for irritability of the bladder, which wakes her at that interval. I may mention that the disease has affected the base of the bladder, and this I believe is the cause of the irritability.

I was induced to try the silicon lozenges from the fact that my father, Dr. R. F. Battye (who was the first to use silica in the treatment of cancer), had attended a patient in the same house who had died of cancer, but had suffered no pain after the first fortnight, and remained free from pain till her death, which occurred about a year after.

If not trespassing too much on your valuable space I will send you from time to time short notes of the progress of this case.

I am, Sir, yours respectfully,

J. H. Battye, M.D.

St. George's-road, London, S.W., Nov. 23rd, 1880.

P.S.—The formula for "silicon lozenges" is contained in the *Edinburgh Medical Journal* for November, 1874.

"SHAM DOCTORS AND UNQUALIFIED PRACTITIONERS."

To the Editor of THE LANCET.

SIR,—In your edition of January 8th, 1881, you report two cases of sham doctors in our neighbourhood. I am quite sure if you knew the facts of both cases you would have justly treated them in a different manner.

In the first case, on page 65, an old qualified man, who has a private income, I believe, derived from a patent medicine, has been able to compete with his brother practitioners by allowing people to run up bills for various periods varying from five to thirteen years, has had a mania for rushing in and out of people's residences, and at last, when worn out, employs a man, who has never studied at or entered any hospital, to do his work. With a dog-in-the-manger spirit, he has tried to retain his hold against his fellows. This man (the assistant), after a run of three years, is sued by the Medical Defence Association, and instead of their producing over seventy fraudulent death certificates (as can be proved by the registrar who holds them), he is only summoned upon three, and fined a paltry sum.

In the second case (page 67), Mr. Wordley, a gentleman who served five years as an apprentice to a legally qualified practitioner, then went to Australia, served as an assistant, returned to England in 1870, then again served as an assistant, and received good testimonials, opened a dispensary under my surveillance in Great Suffolk-street, Borough, and through his steady working has made it a great success—so much so as to create a jealousy amongst a clique. Acting upon my advice, he entered Guy's Hospital in 1874, at forty-three years of age, and so won the good opinion of several of the professors that they did not refuse to meet him in consultation. The dispensary mentioned was carried on in the most legitimate manner—no advertisements, no prices published. I attended at stated hours, and if any important case occurred I was sent for immediately at any hour.

On Dec. 21st, 1880, Mr. Wordley was called to see a poor woman at 10.30 P.M. He found she was an old sufferer from chronic disease; from her poverty he knew it would be useless putting them to the expense of sending for me, and as he had to present himself the next day for examination at the Apothecaries' Hall, he told the friends to send for the parish medical officer, and generously gave them the fee to get the poor woman nourishment. Five days afterwards he was surprised by the friends coming and asking him for a certificate of death, as they had not followed his advice. He declined to give them one, as he had only seen the case once, and censured them for not calling in the parish aid; but as the friends did not wish for an inquest, he wrote a certificate, stating what was the matter with the patient when he saw her, signed his name as A. W. Wordley, L.S.A., he having succeeded in obtaining his diploma, after six years' study, on Dec. 23rd, at the age of forty-nine.

I am quite sure that, after my knowledge of your impartiality during the past twenty-seven years, you would not have inserted the article you did if the facts had been known. The Apothecaries' Hall and the Medical Council can prove the veracity of my statement as regards his qualification, and I consider a man who will enter the hospital at forty-three years of age, go through the microscopical minutiæ required now by the Examining Boards, deserves the highest commendation, and I beg to suggest that it is quite time that the discretionary powers assumed (?) or given (?) to coroners, coroners' officers, registrars, &c., and the false and undignified position occupied by medical men in these cases should be looked into by the Medical Council, and in a future letter (with your permission) I can open the eyes of the whole profession to facts, and not fables.—I am, Sir, yours truly,

GEORGE DANIEL HARDING, L.R.C.P., M.R.C.S.

Lorrimore-street, Jan. 12th, 1881.

To the Editor of THE LANCET.

SIR,—In reference to the inquest upon Martha Lusty, will you kindly insert the following: The daughter requested me to see her mother at 7, Bancor-court, White-street (not Bangor-terrace, Southwark-bridge-road, as stated,) at 10.30 P.M. on the 21st ult., as she feared she would not survive the night. I did so gratuitously, and advised her removal to the Infirmary. I directed her daughter how to proceed, and she promised to see to it early in the morning. They appeared to be in great poverty, and depending entirely upon the daughter's earnings. Six days after she applied for a certificate (when I thought the woman in the Infirmary), and having seen her only once I did not feel justified in giving one—hence the inquest. The above is an illustration of the "fraudulent and dangerous practices" commented on by the Jury.

I am, Sir, your obedient servant,

A. W. WORDLEY, L.S.A. Lond.

Indicus.—Our correspondent will find the information he requires so far as regards the military service in the Army Medical Warrant of Nov. 27th, 1879, published in the Army Circular of Dec. 2nd, 1879.

Leo.—Dallas's Manual.

Librarian.—Messrs. Williams and Norgate, Henrietta-street, Covent-garden.

Læsus.—Next week.

Dr. John Davies.—We cannot advise. Consult a solicitor.

Dr. Lewins.—We are compelled to dissent from our correspondent as to the utility of further discussion in the matter, at all events for the present.

THE MEDICAL STAFF OF GREAT HOSPITALS.

To the Editor of THE LANCET.

SIR,—In the important and perhaps very best eclectic periodical of any in Europe, whose articles attract alike the serious attention of THE LANCET, the *Saturday Review*, &c., and of the more ephemeral journalistic sheets, the *Revue des Deux Mondes*, November 1st, 1880 (meaning the two worlds—*l'ordre moral et l'ordre* or *monde physique* I presume), Monsieur Léon Lefort, of the Academy of Medicine, has been enlightening the public as to the amount of administrative influence claimed and granted to civil hospital surgeons in a manner which seems to apply not inaptly to the present controversy at Guy's. A few translated passages will not perhaps be uninteresting to all of us.

"We are not, let the Secretary of State (M. le Ministre) know it once for all, subordinated to the administrative body of the hospital in the ordinary sense of the word. The doctor of a civil hospital claims the right to weigh with the whole influence of his scientific authority the direction of the hospital service, but he would not consent to be the manager (*directeur*) of the hospital." M. Lefort had stated previously that even in the army, "It could never be his (the surgeon's) province to conclude contracts and bargains or collect supplies. The question is not one of substituting the medical element for the administrative one, but to apportion to each his legitimate share of action and influence" (p. 186). The whole admirable article shows the terrible consequences of making a medical department subordinate to any authority but that of the general and his staff, the commanding officer, &c., as in all military affairs, and not, as still in the French army alone almost now, to what is called l'Administration Intendance, &c., neither, in fact, more nor less than our commissariat and its branches—transport train, purveyors' department, &c. Thus two thousand sick were crammed into the Péra Hospital in spite of the reiterated warnings of Baudens, Michel Lévy, and others, with the result of widespread and devastating pyæmia (*infection purulente*) and septicæmia. Michel Lévy, like our two distinguished men at Guy's, resigned in disgust. The essay "is extant, and written in very choice" French. It is already said to have engaged the serious attention of the Minister of War, General Farre. It does credit to Professor Lefort and to the great review which has welcomed him to its pages. It is impossible in a short letter to give more than a glance at the many good and outspoken things it contains.

I am, &c., yours most sincerely,

CAMERON MACDOWALL, F.R.C.S.E., &c.,
Bombay Army.

E.I.U.S. Club, 14, St. James's-square, S.W.

Studiens.—Application might be made to Moore and Co., St. Mary-axe, E.C.

J. S.—We regret that we cannot give our correspondent the information he requires. We believe the papers have not been published.

Mr. M. W. Hilles.—If our correspondent will forward a specimen of the instrument it shall have our attention.

Ne cede Malis.—The case is peculiar, and should be settled amicably. It is one for consideration on both sides. The terms should have been arranged before for an attendance so inconvenient to the practitioner. Abstractly his charge per visit is not unreasonable, but for a regular medical attendance it seems so.

THE PRACTICE OF MEDICINE AND SURGERY ABROAD.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers would inform me what qualifications are necessary for the practice of medicine and surgery in the United States, Canada, or Egypt.—I am, Sir, yours faithfully,

Jan. 10th, 1881. M.R.C.S.

Can Surgeons claim Midwifery Fees?—Certainly; but no legal qualification seems to be necessary to claim midwifery fees. The claim of a midwife would be recognised as simply based on contract.

Dr. Hawkes.—The paper will appear shortly.

ASSOCIATION OF TONSILLITIS AND RHEUMATISM.

To the Editor of THE LANCET.

SIR,—I am somewhat surprised at the association of tonsillitis and rheumatism being treated as a novelty. Dr. R. Liveing pointed it out to his clinical class at the Middlesex in 1874, but not as anything new, and he told us to give colchicum a good trial in all cases of recurrent quinsy. In a great number of cases I have been able to trace the connexion, quinsy seeming in certain members of rheumatic families to take the place of the articular affection, and I have had at least one proof of the danger of treating tonsillitis by an abortive process without due consideration, my patient as the result being laid up for sixteen weeks with subacute rheumatism. In many cases the connexion might only prove a parallel to gonorrhœal rheumatism as the result of an aborted gonorrhœa, but beyond that there is a decided association (of an almost hereditary character), which must be evident to anyone who has his attention drawn to it.

I am, Sir, yours, &c.,

Abingdon, Dec. 28th, 1880. GEORGE GOSSET.

THE "COMMERCIAL" ASPECTS OF MEDICINE.

To the Editor of THE LANCET.

SIR,—The suggestive article in THE LANCET of the 1st instant on the classing of the medical profession as "commercial" may receive a further illustration of the existing tendency in this direction. Some allowance may perhaps be fairly made for the compilers of a post-office directory in taking a too limited view of the proper relation of things; but what can be said for a leading college at Cambridge which, in the printed form sent at the end of each term to the parents or guardians of its students, places under the heading "tradesmen's bills" that of the surgeon? I give you privately the name of this college, not knowing whether or not a similar practice prevails at other colleges. That it should exist at all at Cambridge is perhaps the more remarkable since for several years past the medical department of the university cannot be said to have neglected any opportunity of advertising its desire to attract students to its teaching.

I remain, Sir, your obedient servant,

Jan. 8th, 1881. AN OLD SUBSCRIBER TO THE LANCET.

W. Y. Coombe.—There are several such institutions—e.g., Copped Hall Green, Waltham; Llanover-road, Sudbury; Box-grove, Tylehurst, Reading; Limpsfield, Surrey.

DISTRICT MEDICAL OFFICERS AS MEDICAL OFFICERS OF HEALTH.

To the Editor of THE LANCET.

SIR,—From time to time I have observed in your columns remarks deprecating the appointment of the same individual to the posts of district medical officer and medical officer of health. In your last week's issue you apparently assume that if the health officer be not also union medical officer, he will be more independent, and not in private practice. This is not so in many cases. I think your remarks are very theoretical, and display a want of information as to the inconvenience arising from divided authority and responsibility.

In several districts of this union both appointments have for many years been held by the same individual. The result has been very satisfactory in every way. In one unfortunate district, however, the reverse is the case. The result has been perpetual ill-feeling between the two officers for many years, which ill-feeling has been duly handed down to their successors.

The district medical officer in cases of small-pox, &c., visits and effects the removal of the patients, gives directions to the surveyor of the local authority as to disinfection and any other steps necessary. The officer of health never goes near the cases, but simply includes them in his fortnightly report to the local committee, together with information copied from the medical relief book. In other words, the district medical officer has the risk and responsibility, while the other useless mortal has the pay—pretty liberal, too—for the duties of a position which he himself once aptly described as "useless and anomalous," and a member of the Local Committee termed a sinecure.

This is, to say the least of it, unjust. I think your editorial opinion would undergo considerable modification if you could for a short time fill either of the above positions and feel the consequences of setting two men to worry each other, and at the same time deprive both of one-half of the power one would have if possessed of both appointments. I see no objection to the combined scheme with one officer of health not in private practice. Even then the individual cannot be ubiquitous, or so well acquainted with the districts as the union medical officers, or in a position to act so promptly. Then you have to compensate the present officers of health if they are to be superseded, especially our "useless and anomalous" friend above mentioned.

I am, Sir, yours faithfully,

Jan. 1881. PALINURUS.

*** We give space to this curious and inconsequent letter in illustration of our remarks last week. We are content with the recorded experience of the Local Government Board on the subject.—ED. L.

MEDICAL ADVERTISING AND THE SYDNEY INFIRMARY.

A most reprehensible practice of puffing medical men in connexion with cases in the infirmary of Sydney seems to prevail. An absurd instance is before us, in which "Dr. Marshall" is represented as exceeding all the surgery of Europe by curing a case of fistula. Who is to blame for this?

"*Aut viam inveniam, aut (Deo juvante) faciam.*"—Our correspondent acted rightly.

ABSTRACT OF A

Clinical Lecture

ON THE

DIFFERENTIAL DIAGNOSIS BETWEEN CERTAIN HYSTERICAL CONDITIONS AND MYELITIS.

Delivered at the National Hospital for the Paralysed and Epileptic, on Dec. 16th, 1880,

By THOMAS BUZZARD, M.D., F.R.C.P.

Gentlemen,—The subject of nervous mimicry of organic disease in general has been, as you are well aware, admirably discussssed by Sir James Paget. It is not my intention to take up your time by attempts to add anything of importance on the general question to the account which we owe to one whose unrivalled experience has been recorded with consummate literary skill. But I wish to bring before you to-day some cases of recent occurrence to illustrate the difficulties which often occur in distinguishing between certain forms of acute and chronic myelitis, and hysterical imitations of the symptoms belonging to such conditions. Opportunity will thus be given me for referring to points of diagnosis that may assist in preserving us from errors which are of very frequent occurrence. I may say at once that it is often extremely difficult, and occasionally for a long time impossible, to arrive at a confident opinion in cases of this kind. Yet, unless we can do so, should the case be one of hysteria, we stand little or no chance of curing our patient, and for obvious reasons it is a still more serious matter if we mistake a case of organic disease of the spinal cord for one of hysteria.

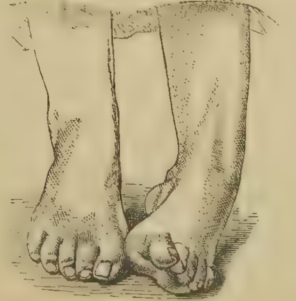
But, first, let me mention the forms of disease of the spinal cord which, according to my observation, are the most likely to be confounded with hysteria, and I will here refer to Grasset's classification. On the side of *systematic* myelitis there is first spastic spinal paralysis from sclerosis of the lateral columns of the cord, and next acute anterior polio-myelitis, that affection of the anterior cornua upon which I lectured last week. In my experience tabes dorsalis is rarely or never imitated by hysteria. I certainly did see not long ago a lady in whom a complete and temporary loss of the muscular sense in the lower extremities imitated one of the symptoms of locomotor ataxia, and produced a slight incoördination in the gait, but the diagnosis was easy, owing to the entire absence of any corroborative symptoms. On the side of *diffuse* myelitis—i.e., myelitis invading without distinction any or all of the regions of the cord,—two forms alone need special reference. Of the first, a circumscribed and subacute variety (most often perhaps when it attacks the dorso-lumbar region); of the second, that special form which we know as insular or disseminated cerebro-spinal sclerosis. Of this last I shall only say now that it is as regards this form of myelitis, and its imitation by hysteria, according to what I have seen, that an insuperable difficulty of diagnosis is very apt to occur. I propose to reserve this important variety for consideration in a future lecture. On the present occasion I shall refer to cases in which subacute myelitis, anterior poliomyelitis, and lateral sclerosis come in question.

Early in last summer a school-girl, aged fourteen, was admitted into the hospital unable to stand without support. She could not walk, but with a stick in one hand and an arm to lean upon, she would advance, like a kangaroo, by a series of springs. It was said she could spring up three stairs at a time. Her ankles were constantly kept bound firmly together, and with this arrangement she was comfortable enough. When, however, the bandage was removed there was sudden, instantaneous adduction and rotation inwards of the knees, and consequent separation of the ankles, each foot being at the same time turned strongly inwards. In its rapidity the movement resembled the action of a gunlock. The muscles would then be found rigidly contracted, and the girl would cry out with the pain which the spasm evidently occasioned her. The patellar tendon-reflex was in excess on each side, and there was also ankle clonus. From notes taken by Mr. Broster, it appears that about two years previously some water had been let fall from above on her head (just behind the right ear) as she looked out of window. This gave her a very great shock, and was followed by earache, headache, gradually increasing deafness, and in three months by a state of delirium and "childishness," with loss of sight, hearing, taste, and smell. The delirium lasted a week. After this there was great pain in the head, and the legs and arms used to be violently drawn and twitched. There was also from the description some opisthotonos. These symptoms continued for two or three months. The sight then returned suddenly, the spasms grew less, the hearing and sense of smell were restored, and she gradually got into the state exhibited on admission, in which she had then remained for a twelvemonth. The strongest faradaic currents producing a slight and only temporary relaxation of the rigidity, the girl, on the sixth day of her admission into hospital, was placed under the influence of ether, and as she became insensible the muscles relaxed. She was then allowed to recover; but when consciousness had apparently only half returned, the legs resumed with extreme suddenness their position of adduction and rotation inwards. They were not, however, now so rigid, and she was induced (intoxicated by ether as she still was) to stand and walk feebly. She was then again (and still more completely) anæsthetised, and whilst unconscious the legs were rotated outwards and abducted. This time they retained their new position when the girl recovered consciousness. The left foot was then perfectly straight, but there was still some inversion of the right. In this one ankle clonus could still be readily obtained by dorsal flexion, and also, though to a less degree, in the left foot. After this there was no return of rigidity, and on the following day she walked well. A week after the etherisation no ankle clonus could be induced. She was sent home perfectly well within a fortnight of her admission. I heard the other day that she is in excellent health.

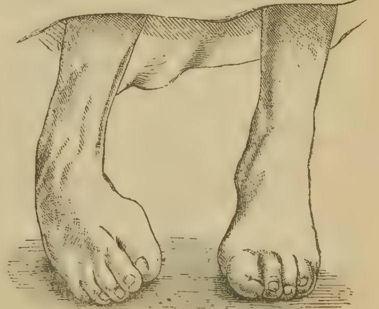
We had the advantage here of a *complete* history, and the diagnosis was easy. But I can quite understand that during the progress of this case there must have been difficulty especially in excluding cerebral and probably spinal meningitis, and that the rigidity with exaggerated reflex would have a *primâ facie* resemblance to that arising from sclerosis of the lateral columns secondary to a lesion above. But the course of the disease—and especially the opisthotonos followed by *sudden* return of sight—was conclusive of hysteria. Moreover, had the rigidity depended on bilateral sclerosis, the jumping feats would have been absolutely impossible. Added to this, the gluteus maximus, the most important muscle in jumping, is also a rotator outwards, and this movement had been in complete abeyance—an inconsistency of the most striking kind. Now, this girl recovered rapidly because we were absolutely sure of our diagnosis. You cannot cure a case of hysteria so long as you have any serious doubts about its nature.

In the diagram before us (drawn from photographs which Dr. Gowers kindly took for me) are two pairs of feet, which present a certain superficial resemblance. In each the inner border is drawn up into the position of a not severe varus. They are the feet of two young women who were in the hospital at the same time, and there is this special point of

B.



F.



interest about them, that F——, really a case of acute myelitis, had been treated as a case of hysteria, and B——, really a case of hysteria, came in as a paralytic. I show you the patient F——. This girl, aged sixteen, was admitted last April, on account of loss of power in both her legs, which had existed for three months. In the early days of her illness she had been treated by cold shower-baths administered daily, and strong currents from a magneto-electric machine to her legs, continued, she says, every day for a month. The history of her symptoms is briefly as follows. A feeling of pins and needles from the waist downwards was followed next day by weakness and pain in the legs, and on the following morning by total inability to move them, and complete anæsthesia. Some bladder trouble occurred for nine days, and want of control of bowels (from her account) for some weeks. Her description, however, is not very clear on this point. Two months after her attack she for the first time succeeded in moving her left leg. The right could not be moved till five weeks later; sensation returned in the left leg six weeks after the onset, and a week later in the right. When she came here she could lift the left heel two feet off the bed, and bend the knee. On the right side she could only make the faintest effort at flexing the hip and ankle-joint, and could not bend the knee. The right foot lay in a position of talipes varus, which could be reduced by the hand, but not by the patient's volition. The patellar tendon-reflex and sole-reflex were absent on the right side, feeble on the left. The electrical examination was most important. Whilst the muscles of the *left* limb responded to induced currents but little stronger than normal, the peroneus longus of the right side showed no reaction to the greatest strength of Stöhrer's two-celled induction-machine, and the anterior tibial group required much stronger currents than in health. The right quadriceps extensor failed to contract to either induced or voltaic current. At the present time the right peroneus longus reacts to interruptions of twenty to thirty cells voltaic current, the vastus internus to sixteen cells, the externus to twenty cells. None of these muscles react to faradaism, to which the tibialis anticus alone responds nearly normally. The tibialis anticus, which has all along been less affected than the other muscles, determines the position of the foot, its antagonist, the peroneus longus, which holds down the head of the first metatarsal bone being paralysed.

In this case the electrical examination alone is sufficient to exclude hysteria. Duchenne wrote that the electro-muscular contractility was normal in hysterical paralysis. According to my observations there are exceptions to this, which, however, is doubtless the rule. Occasionally there is a distinct, although slight, lowering of electrical excitability in the muscles in hysterical paralysis, where this has been of long duration. The lowering of excitability, however, applies to both forms of electrical excitation, and in that respect differs from the "reaction of degeneration" where the decrease in faradaic excitability is usually accompanied by increased excitability to the voltaic current. We *never* see in hysteria the various muscles of one limb showing differing degrees of abnormality of response to faradaism, from a condition of total absence perhaps in some, to nearly a natural state in others. Moreover, according to my observation, in hysteria applications of electrical stimulus (and especially of the voltaic current) on one or two occasions usually suffice to restore the natural excitability of the muscles (equally in all), which has simply declined apparently through disuse. A difficulty can only arise where the observer has but one opportunity of testing the electrical condition, and it is then quite possible to occur. It must be remembered that, as a distinct lowering of faradaic excitability almost invariably signifies organic change in a nerve or nerve centre, a diagnosis of hysteria can never safely be arrived at whilst that condition persists. On the other hand, I need scarcely remind you that the preservation of a completely normal faradaic excitability in the muscles of a limb does not show that that limb is not paralysed. It would be hardly necessary to refer to this, but that I once heard it stated in a court of law that the plaintiff was certainly not paralysed, since the muscles of the limbs contracted to electrical currents! In cases of paralysis, it is only when the integrity of the grey matter of the anterior horn is disturbed, or when there is some lesion of the anterior root of the nerve, that you find decided loss of electric excitability. You may have, and frequently do have, complete paraplegia with all the muscles responding normally.

As regards the patellar tendon-reflex, I have never seen it lost in a case which proved in the sequel to be hysterical, although I am not prepared to deny the possibility of its absence in such circumstances, if the muscle has suffered from lengthened disuse.

The other patient, B——, aged twenty-four, came in unable to stand without support. In trying to walk between two persons the left foot was seen to be in a position of varus, as shown in diagram, and as she lay in bed the foot occupied the same position, although it was not then quite so determined. Now, in her case the faradaic excitability of the muscles of both lower extremities was found to be quite normal. The patellar tendon-reflex was very excessive on both sides, and most marked on the left. There was no ankle clonus. The sole-reflex in the left foot appeared normal. In the right tickling was at first followed by no response, but being persevered in the limbs drew up strongly. After the daily use of the wire brush, with induced currents, for two or three weeks, and general treatment, the patient was able to walk round Queen-square without help; next day a still longer distance, and soon went out of the hospital recovered.

Now this patient had suffered for three years from convulsive fits, in which she was described as losing her consciousness. The occurrence of fits in such cases as these may materially aid our diagnosis, or, on the other hand, may lead us into error. Supposing that the patient who is apparently paralysed has attacks of typical hysterical eclampsia, we have in them a symptom which, when associated with others, may tend to render a diagnosis of hysteria certain. In the present instance, although the first fit occurred after the patient had been frightened by being locked up in a room, and was therefore presumably hysterical, the attacks, some of which were witnessed in the hospital, were of an epileptoid rather than hysterical character, and their occurrence lent us no aid. As I said just now, they may easily lead to error. About a year ago I admitted a young woman on account of paralysis in all four limbs. She was described by those who sought admission for her as a case of hysterical paralysis. Seven months before she came here the patient had complained of pain in her back, side, and head. The pain was very bad on the vertex. Next she became very weak on her legs, and moved them in an incoördinate manner. At this time there was great weakness of the right hand, and the right side of the face was paralysed. Soon she became unable to walk at all.

A month after she had begun to be ill this patient had a fit, and these had been repeated on five or six occasions before her admission. I have little doubt that it was the occurrence of these fits, associated as they were with paralytic symptoms, confined at first to the lower extremities, which gave rise to the diagnosis of hysteria in this instance. The apparent want of connexion between the two symptoms would be suggestive (unless the possible existence of multiple lesion were insisted upon) of the inconsistencies of certain forms of hysteria.

When we came to examine this patient with the ophthalmoscope (which we never omit doing), it was found that she had optic neuritis. This fact, of course, immediately carried us a long way on to a diagnosis of serious brain lesion. Moreover, in addition to this she had a bedsore, and the presence of this alone was significative of organic disease.

Let me call your attention to the note respecting the state of the muscles of this patient's legs on admission. "Lower limbs powerless; not the slightest power of movement; *no wasting*, no rigidity. No difference between the two limbs. The muscles respond to faradaic currents of somewhat higher strength than is required normally." (As the case advanced there was much wasting, and the legs were rigidly drawn up.) I shall have occasion to refer to the question of wasting of muscles and its diagnostic value. For my present purpose it is only necessary to add that this patient grew worse and worse, that in spite of the most diligent attention, her bedsores extended, and that she died some months after admission. The autopsy showed basilar meningitis and spinal meningo-myelitis, the cord being disorganised and softened throughout. The patient, it should be said, was the subject of inherited syphilis.

I lately saw in consultation in the course of a week three ladies, each of whom had been thought to be suffering from hysterical paralysis, although in two cases there had been some difference of opinion on the part of those who had seen the patient. The first proved to be a case of advanced

Pott's disease of the spinal column with paraplegia. The second was an example of anterior polio-myelitis. Three months previously this patient, a lady aged twenty-six, had been attacked with feverishness, pain in the back, and aching in the legs. The following morning she was weak in her legs, and next day had entirely lost the use of them. There was no affection of sensibility or of the bladder. I found the patellar tendon-reflex absent in each limb, the muscles of both thighs wasted and flabby. Powerfully supported she could move her legs a very little, but both feet were dropped. The cutaneous-reflex from the sole was good on each side. I learned from the gentleman in attendance, who (as it happens) is able to give skilled evidence on the point, that when examined electrically a short time previously to my visit, the muscles gave typical "reaction of degeneration" in varying degrees. I found that percussion produced contraction in the right tibialis anticus and peroneus longus, but not in the left. The "reaction of degeneration" and the varying degrees of response to mechanical and electrical stimulation showed conclusively that the case was not one of hysteria. It is an example of acute anterior polio-myelitis. The third patient had been paralysed in both legs for two and a half years, and in the left arm for nine months. Uterine troubles and pelvic cellulitis had preceded the paralysis, and an abscess had discharged through the bladder. The loss of power had been gradual, and took a few months to become complete. It was accompanied by cramps and some loss of sensation. The patient was in bed, and unable to move her legs at all, and the feet were dropped; the legs were wasted. There had never been bedsores. The urine (always acid) had been drawn off for two years, the use of the catheter having commenced, as I learned, in connexion with the local troubles of the bladder from the abscess. The patellar tendon-reflex was here distinctly present, but not strong, on each side. Tickling the soles was not felt, and produced no reflex. The legs were not contracted, but the joints were somewhat stiff. Strong induced currents were not felt, and there was not at first free response of contraction in the muscles. A strong constant current was then applied, and the interruptions of this the patient felt very much. A return being then made to faradaism the currents were now felt acutely, and the contraction of the muscles became nearly normal, in proportion to their wasted bulk. Moreover, the muscles of the thighs were now used in a quasi-voluntary manner to draw up the legs in an endeavour, as it appeared, to escape the painful application. The left arm, which lay across the chest, was neither rigid nor lax, but as if asleep. When the patient's attention was engaged in another direction the arm was held up, and being then let go, it subsided gradually and slowly. A strong opinion was expressed that the condition was hysterical, chiefly on the following grounds. The gradual loss of power, with loss of sensation if it were organic, must have been due to more or less diffuse myelitis, involving grey as well as white matter. The situation of this must have been either in the lumbar portion of the cord, whence the nerves proceed to the lower extremities, or at some point above this. Had it been in the former, the patellar tendon-reflex would have been absent, and the muscles would have lost their faradaic excitability. If it had been above there would necessarily have been by this time descending degenerative changes in the lateral columns, which would have shown themselves by more or less rigidity and exaggerated reflex. Had myelitis been so extensive as to involve the whole of the lower half of the cord in softening, there must have been bedsores and difficulties with the rectum. The result of the case has justified the opinion which was arrived at by those who consulted upon it. Under careful feeding, moral treatment, and faradisation of the skin with the wire brush, the patient speedily regained the use of the arm, was shortly afterwards able to walk to a certain extent, and is now, as I learn, quite recovered.

In this case, as I have seen in many belonging to the class of hysteria, the epidermis, which had arrived at extraordinary thickness, apparently from disuse of the limbs, offered great resistance to the passage of electric currents. In these circumstances a more than usual amount of care in thorough soaking and rubbing of the skin, as well as in selecting the motor point, is necessary in order to avoid fallacies.[1] This woman's legs were very thin. There is, I think, a very common notion that the existence of wasting negatives hysteria. But a disused limb is of course liable to emaciate. The only way to distinguish with certainty between this wasting and that which arises from change in the trophic centre in the spinal cord, or from disease of a nerve-trunk, is by observing the condition of faradaic excitability, and seeking for any qualitative changes on interruption of the voltaic current. I have reason to think that not a few cases of anterior acute polio-myelitis occurring in young females pass as examples of hysterical paraplegia, owing to omission to test carefully the state of the muscles by electrical currents. Such cases may sometimes recover in the course of several months, and then the result is supposed to prove the truth of the diagnosis.

Absence of reflex from the sole of the foot is a very constant symptom in hysterical paraplegia. Where this coexists with normal electrical contractility of the muscles of the lower extremities and normal tendon-reflex the case may be looked upon with suspicion, although this is not of itself sufficient to exclude organic disease. A persistence in the application of a stimulus to the sole will, in hysterical cases, frequently, but not always, succeed in a few minutes in provoking a response.

Preservation of the roundness and firmness of a limb is often thought to be incompatible with paralysis. This is a dangerous error. In the case of Pott's disease, which I have referred to (the patient died a few weeks afterwards), the lower extremities were rounded, well nourished, and firm to the touch. In cases of localised myelitis of the dorsal region of the cord, followed by descending sclerosis of the lateral columns, there is frequently unusual firmness and tonicity of the lower extremities, which may appear, indeed, to be models of muscular development. This is important to remember, as hysterical imitations of lateral sclerosis are not uncommon. The most frequent, however, and at the same time the most difficult of distinction, is a condition closely resembling disseminated cerebro-spinal sclerosis. This must be reserved for future consideration.

A HISTORY OF THREE CASES IN WHICH A WARTY GROWTH WAS REMOVED FROM ONE OF THE VOCAL CORDS BY THE AID OF THE LARYNGOSCOPE.

BY GEORGE JOHNSON, M.D., F.R.S.,
PROFESSOR OF CLINICAL MEDICINE, SENIOR PHYSICIAN TO KING'S COLLEGE HOSPITAL.

IN the 51st volume of the Medico-Chirurgical Transactions I have given the history of seven cases in which I removed warty or papillomatous growths from the vocal cords. In the present communication I propose to describe briefly three similar cases that have more recently come under my observation and treatment.

CASE 1.—Susannah M——, aged sixty-three, was admitted into Twining ward on Oct. 16th, 1875, on account of hoarseness and dyspnœa. The hoarseness began two years before, and had gradually increased up to the time of admission. About ten weeks previously she began to suffer from difficulty of breathing, especially on exertion. The breathing was attended with a rattling noise in the throat, and sometimes with a sensation as of something flapping about in the upper part of the windpipe. For some time the breathing had been more difficult when lying down at night, and her sleep had been much disturbed in consequence. There had been a feeling of uneasiness, but no actual pain in the throat. She had had but little cough, and no expectoration. There was no difficulty of swallowing. Since the breathing had been difficult she had lost flesh and colour. The voice was now (at the date of admission) reduced to a whisper, and both inspiration and expiration were attended with a moist, wheezy stridor. On looking into the larynx, the cause of the aphonia and dyspnœa was obvious. Attached to the anterior part of the left vocal cord there was a warty tumour of the size and shape of a small filbert. This wart-like tumour occupied at least two-thirds of the area of the glottis. Although it appeared to have a broad attachment to the vocal cord, it was moved by the current of air, so that it rotated in a downward direction during inspiration, and upwards in expiration. The left vocal cord was entirely concealed by the growth, but the right cord was plainly visible and appeared quite normal.

---

[1] As the motor point frequently varies as regards its position from that indicated in works on electro-therapeutics, I am in the habit of testing in the following manner: The limb having been very thoroughly wetted and rubbed with hot water, and the induction machine arranged to give a somewhat stronger current than is necessary in health, one rheophore is applied to an indifferent part of the body (as e.g. the sacral region), and the other is moved about the skin of the limb at the part where the motor point is expected to be found. It will soon be perceived, by comparison, at what point of application the most energetic contraction is excited. The skin is then marked at this spot with a wetted aniline pencil, and the operation is repeated on the opposite limb, as well as for other muscles. The motor points having thus been ascertained, it is easy, by graduating the machine, to discover the weakest current which will cause contraction and compare it with that required in health.

On the 26th October I made an attempt to remove the growth by the laryngeal écraseur, but the patient was nervous, and her nervousness was increased by seeing a crowd of students surrounding her while watching our proceedings; so after one or two unsuccessful attempts to seize the tumour I determined to wait for a more favourable opportunity. Two days afterwards, on the 28th, I obtained the assistance of the house-physician, Dr. Batterbury, who held the patient's tongue, and I soon succeeded in removing nearly the whole of the growth. First, with the écraseur I pulled off a piece nearly half an inch long; then two smaller pieces by the same means; after which, with the laryngeal forceps I removed a piece as large as a horse-bean. There was not much bleeding—these growths are not very vascular, and they never bleed much,—but the little bleeding that occurred after the removal of the first piece increased the obstruction of the glottis and caused some temporary dyspnœa. After the removal of the last large piece she expressed a feeling of relief, and the breathing ceased to be stridulous. On the following day she stated that she had slept better than she had done for some weeks past. On inspection we found only a small nodule of the warty growth near the ridge of the glottis. This was afterwards touched on three or four occasions with solid nitrate of silver by means of the laryngeal porte-caustique, and it entirely disappeared. Her voice was completely restored.

The laryngoscope enabled us in this case not only to make an exact diagnosis, but also to remove a disease which ere long would have caused a fatal impediment to respiration. A few years ago, before that simple instrument had been brought into use, we could only have guessed at the nature of the disease, and we should most likely have guessed wrong. The result would probably have been that when the growth increased until it threatened life, tracheotomy would have been performed, and for the rest of her days the voiceless patient would have breathed through the artificial opening in her windpipe. How much happier is the result obtained by the aid of the mirror, not only affording relief from impending suffocation, but complete restoration of the voice.

We know from our experience of similar cases that when a simple warty growth of this kind has been completely removed there is little or no tendency to a return of the disease. I have lately seen two of the cases recorded in my paper in the Medico-Chirurgical Transactions—Cases 4 and 7, one ten years, and the other more than seven years after the removal of the growth. In both cases the larynx remains healthy, and the voice is perfect.

CASE 2.—Mr. G. M. S——, aged fifty, first consulted me on Sept. 7th, 1874. His voice had been feeble since the beginning of the year, and latterly had become more and more so. At the time of his visit the voice was reduced to a rough whisper. A few days before I saw him he had been examined by a laryngoscopist, who told him that he had a growth in his larynx which, if not speedily removed, would increase until it suffocated him. I found a simple warty (papillomatous) growth, about the size of a pea, attached to the right vocal cord near its anterior end, and I advised him to have it removed. He was then living in Scotland, and he said that he must return home at once, but he would come to London in November and submit to the necessary treatment. He, however, did not present himself again until February, 1875, when he stated that five weeks before he had caught a severe cold, which had greatly increased his hoarseness. He was then suffering from bronchial catarrh, limited, however, to the larger bronchi. There was much congestion of the palate and fauces. Inspection of the larynx showed that the growth had now attained the size of a large horse-bean. The patient was very nervous and anxious about himself, and the more so as a most unfavourable opinion of his case had been given by a country practitioner; but he had now come to reside in London, and was prepared to submit to any treatment that was thought necessary. The treatment was rendered unusually difficult by the patient's nervousness, and the extreme sensibility of the fauces. By degrees, however, and after several sittings, the greater part of the growth was removed, partly by the forceps, and partly by the écraseur, but there still remained a broad base of attachment to the vocal cord. This I touched several times with solid nitrate of silver. Each touch of the caustic appeared to cause a shrinking of the remaining growth, until at length, after about three months' treatment, the cord was left smooth and healthy, and the voice was completely restored. This gentleman continues in good health. I have seen him during this present month (Jan., 1881). His voice is quite clear and strong, and inspection by the mirror shows a perfectly healthy larynx. While under treatment he took great interest in my proceedings, and suggested to me a very ingenious metal guard which I had placed on one side of the forceps so as to protect the side of the larynx opposite to the tumour from injury when the forceps are closed. The cure of the preceding case was more troublesome and prolonged, although ultimately complete, than that of any other similar case that I have met with. On the other hand, in the following case I succeeded in effecting an unusually rapid cure.

CASE 3.—The Rev. F. R——, aged about fifty, consulted me first on the 2nd October, 1880. For about a year there had been more or less discomfort in the throat, which was much increased by the excitement of the late election, during which he talked much in spite of the pain and inconvenience it occasioned. The result was, as he states in a written history which he gave me, that his "throat became painful and the voice cracky," and he "felt sometimes as if he was being half strangled." At the time of his visit the voice was rather feeble, and had a reedy sound. He had been told by a laryngoscopist a few days before that there was a small growth on one vocal cord, the removal of which was recommended, but pronounced difficult and doubtful on account of its small size. I found a bright-red wart, about the size of a No. 4 shot, attached to the right vocal cord at its anterior extremity. Although of small size it was sufficiently movable by the respiratory currents of air to fall below the glottis during inspiration, while it was driven upwards and interposed between the cords during vocalisation. The patient was very anxious to have the growth removed, and on October 29th he called to make an appointment for the following day, when the attempt for its removal was to be made. Accordingly he came on the morning of the 30th. It appeared to me scarcely possible to seize so small a growth with the forceps, and I determined to use the écraseur. The first attempt was a failure, but at the second introduction of the instrument I succeeded in seizing and completely removing the entire growth, much to the delight of the patient, whose visit did not occupy altogether more than a quarter of an hour. I last saw him on Nov. 5th, when he called and expressed himself much relieved, and as regarded his throat quite well.

With respect to the kind of instrument best suited for the removal of such growths. When the tumour is of large size and has a broad base, as in the first and second cases here recorded, the laryngeal forceps is perhaps a better instrument than the wire écraseur. I found the forceps very useful in the first two cases, but for the removal of so small a growth as that in the third case I much prefer the écraseur; and I doubt whether this small growth could have been safely removed by the forceps.

The écraseur has this obvious advantage over any form of laryngeal forceps, that, unlike them, it very rarely tears the mucous membrane or seizes any other object than the growth to be removed. It is a perfectly safe and harmless instrument, whereas with the forceps an arytenoid cartilage might be seized and broken or dislocated. The secret of success in using the écraseur consists in bringing the fine steel wire loop exactly opposite the wart at the time when the contact of the instrument excites the sudden closure of the glottis, by which means the tumour is driven into the snare and caught by the sudden retraction of the wire. I have always found that any portions of the morbid growths that are torn off have been tightly held by the wire, which, partially cutting them through and embedding itself in their substance, thus brings them away. I have no reason to suppose that any detached bits of tumour have fallen into the trachea. If, however, this were to happen no harm would result from it; they would probably be expectorated as readily as small masses of mucus are expelled.

Savile-row, W.

CASES OF LARGE CALCULI REMOVED FROM THE BLADDER BY BIGELOW'S OPERATION.

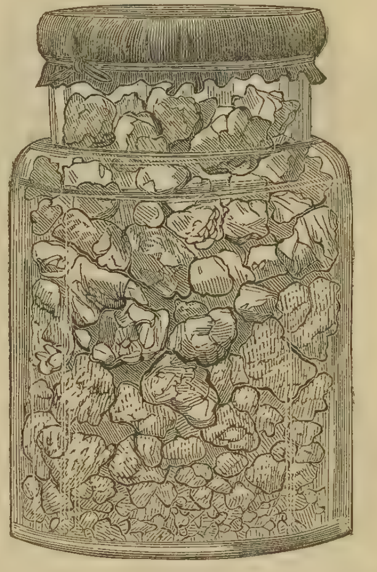
BY W. F. TEEVAN, F.R.C.S., B.A.,
SURGEON TO THE WEST LONDON HOSPITAL.

THE cases I am about to relate are, for many reasons, especially interesting, and prove what Bigelow's operation can accomplish even when the presence of stone is complicated by the existence of grave constitutional disease. The calculi were, I believe, the largest single ones recorded as ever having been removed in this country from the bladder by lithotrity at one sitting. If reference be made to the cases published by Sir Henry Thompson, it will be seen that the weight of the largest stone completely removed by him at one sitting was only 275 grains, whereas the calculi from my patients weighed respectively 486, 610, 880, and 890 grains. One of the patients was suffering from diabetes, another from paralysis. The youngest was fifty-six years old, the eldest seventy-seven. They all made good recoveries, which, with one exception, were very rapid.

I read the results of my first series of one hundred consecutive cases of operation for stone in the bladder at the annual meeting of the British Medical Association at Cork in August, 1879. That series did not include a single instance of Bigelow's operation, for I did not perform my first case of it till six weeks afterwards. Since the above date I have operated on twenty-six patients for stone in the bladder. One of them was a boy, whom I cut by the lateral method, and cured. Three of the adult males were submitted to fragmentation and median lithotomy. I should have preferred lithotrity and external urethrotomy, but the combination was not practicable. Of these, two gentlemen recovered, and one hospital patient, aged sixty-one, died three weeks after the operation from chronic interstitial nephritis. The remaining twenty-two adult males were all relieved of their calculi by lithotrity at one sitting. Of these two died. One of the deaths was that of a gentleman seventy-four years of age, a patient of Dr. Hubbard's, who died three days after the operation. I crushed the stone, which was not much larger than a hazel-nut, with a slender lithotrite, but was unable to pass any evacuating catheter over the very enlarged prostate. From the extent and nature of the hæmorrhage which occurred at times before the operation, and was started at it and persisted, I am led to the conclusion that there was a malignant growth in the bladder; indeed, a week before the operation I said to Dr. Hubbard that "I hoped there was nothing more than the stone." I have been informed by a hospital surgeon of a similar case in his private practice, terminating fatally. The other death was that of an emaciated, broken-down, dissipated man, sixty-nine years old, who died apparently from shock thirty hours after the operation. The post-mortem disclosed chronic cystitis and interstitial nephritis. The stone was phosphatic and weighed 220 grains. I would here wish to refer to the case of a gentleman, fifty-six years old, a patient of Dr. Lionel Beale's, upon whom I operated. He was suffering from asthma and chronic heart disease, and had had hæmoptysis. A week after the removal of a uric-acid calculus weighing 160 grains he was completely cured so far as the surgeon was concerned. He was absolutely free from all pain and could hold his urine, which was quite clear and healthy, for six hours. About a month after the operation his legs began to swell, then he was attacked with hæmoptysis, and died about six weeks from the date of the operation. The following is a copy of Dr. Lionel Beale's certificate:—"Old heart disease, asthma, congestion of the lungs, exhaustion."

CASE 1. *Large oxalate of lime calculus in a diabetic gentleman* (Fig. 1).—On July 20th, 1879, in consultation with Dr. Hewer, I sounded Joseph C——, Esq., sixty-four years old. The patient stated that five years ago he consulted Sir H. Thompson, who sounded him but did not find any stone. He was informed that he did not empty his bladder. The examination was followed by a rigor. Four years ago he began to pass blood freely after carriage exercise, and to be troubled with frequent and difficult micturition. For many years he had suffered from diabetes. I introduced a sound, which struck a hard and large calculus as it entered the bladder. As the urethra was of large calibre and the bladder capacious I advised Bigelow's operation. My examination was followed by a rigor. The urine was examined by Dr. George Harley and found to contain oxalates, sugar, and albumen. One year afterwards the patient made up his mind to be operated on, and I saw him on July 6th, in consultation with Dr. Hewer. He was a strongly-built man, with large abdomen. His face was pale and puffy, and there was much capillary congestion of nose and ears. He had habitually a loud, loose cough. The urine, as examined by Dr. George Harley, was acid, contained a little albumen, one grain of sugar to the ounce; the sp. gr. was 1025. There was "a great abundance of mucus corpuscles and vesical epithelium cells, with blood and pus cells and large crystals of oxalate of lime." The gentleman was born in London, but his father was a native of Suffolk. On July 10th at 2.30 P.M. the patient was put under the influence of ether by Mr. Mills. I introduced a large English lithotrite, but was unable to fairly grasp the stone, which slipped away every time I caught it. I then passed Bigelow's lithotrite, and seized the stone, which was 2⅛ inches in diameter. I then let it go, and having grasped it in its shorter diameter of 1¾ inches, succeeded, in the course of a short time, in breaking it into large pieces, which I further reduced to small fragments and dust with flat-bladed lithotrites. So hard was the calculus that it broke up with loud cracks, distinctly audible to all present. The evacuation of the débris was carried out with No. 26 (F) tube. The operation lasted one hour and a half. The patient was put to bed and his abdomen covered with a large poultice. His diet consisted of milk and barley-water. There was no rise in temperature after the operation, nor was there the slightest hypogastric tenderness. For fifty hours the urine was tinged with blood, and micturition was painful. The patient's progress was rapid and continuous. Five days after the operation he was walking about his garden, and two days later he went for a drive. The weight of the stone, when dried, was fourteen drachms and forty grains. Dr. George Harley pronounced the calculus to be composed of oxalate and carbonate of lime. Dr. Hewer, in a letter recently received from him, thus describes the patient's condition *six months after operation.* "Mr. C—— is quite a different person; able to walk or drive some distance without any discomfort; has lost all his pains. Urine still slightly saccharine. His health is very good. He has a little bronchial irritation occasionally, but that is an old habit of his in the winter." It is worthy of remark that, though the examinations of Sir H. Thompson and myself were followed by rigors, none occurred after the operation, which lasted one hour and a half, during which period numerous instruments were introduced a great many times.

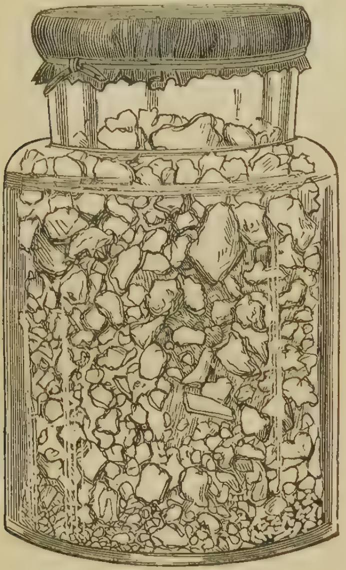
FIG. 1.



CASE 2. *Large phosphatic stone* (Fig. 2).—George W——, a turner, fifty-six years old, was admitted into St. Peter's

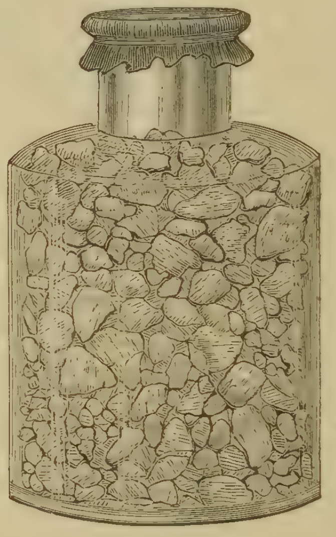
Hospital, on Sept. 21st, 1880, suffering from a stone in his bladder, which I had detected. From notes taken by the house-surgeon, Mr. Whitehouse, it appeared that about two years ago the patient began to be troubled with frequent and painful micturition. The pain was of a scalding character, and extended from the anus to the tip of the penis. He was very pale, and looked much older than he really was, but his body was well-nourished. The urine was rather turbid, acid, and contained oxalates, albumen, and hyaline casts; its sp. gr. was 1016. The man and his parents were all natives of Suffolk. On Oct. 14th at 4 P.M. he was put under the influence of ether by Mr. Knott. As I suspected the stone to be a large one, I incised the meatus externus, and introduced Bigelow's lithotrite, and found the calculus to be 2 in. by $1\frac{3}{4}$ in. After I had fairly broken it to pieces, I pulverised them with slender flat-bladed lithotrites. The evacuation of the débris was effected with a No. 26 (F.) tube. The operation lasted three-quarters of an hour, when the bladder was examined by Mr. Coulson and Mr. Heycock, and pronounced free of stone. The weight of the stone, when dried, was ascertained by Mr. Whitehouse to be fourteen drachms and fifty grains. The next day the patient had a rigor, the temperature rising to 104·4°, but there was no hypogastric tenderness; the urine was but faintly tinged with blood. On Oct. 17th, the temperature was normal, and the water quite clear; the patient had no pain of any kind, and felt quite well; two days later he left his bed. On Oct. 28th he quitted the hospital in all respects quite well, able to hold his urine for six hours; it was acid, and contained neither albumen nor phosphates. He resumed work shortly afterwards, and has pursued it uninterruptedly to the present time.

Fig. 2.



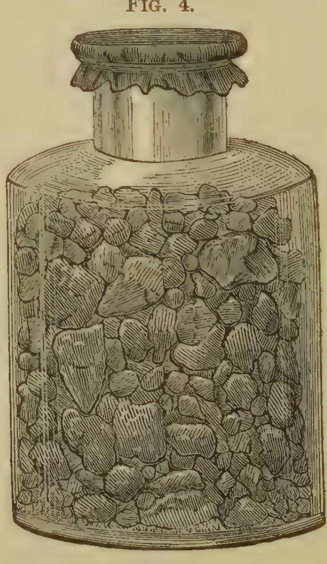
Case 3. *Large uric-acid stone* (Fig. 3).—Robert C——, formerly a farmer, seventy-seven years of age, was admitted into St. Peter's Hospital on Oct. 4th, 1880, suffering from a calculus which I had detected. From notes taken by the house-surgeon, Mr. Whitehouse, it appeared that for some years past the patient had suffered great pain whilst making water. For the last eighteen months his urine had dribbled away night and day. He had a florid, healthy look, but had lost all his teeth, and was feeble and bent. He had a chronic cough. The urine, which was neutral, contained some albumen and phosphates; its sp. gr. was 1012. He was born in Lincolnshire, but did not know where his parents came from. On Oct. 13th, at 2.30 P.M., the patient was put under the influence of ether by Mr. Knott. As the urethra would not permit of the introduction of Bigelow's lithotrite, even after the meatus externus had been incised, I passed a strong fenestrated instrument, and seized the stone, which was apparently spheroidal, and one inch and a half in diameter. Having broken the calculus, which was excessively hard, into fragments, I effected their further reduction with slender flat-bladed lithotrites. The evacuation of the débris was carried out through a No. 24 (F.) tube. The bladder having been examined by Mr. Coulson, Mr. Heycock, and myself, and pronounced free from stone, the patient was put to bed, the operation having occupied an hour and a quarter. The weight of the dried débris, as ascertained by Mr. Whitehouse, was ten drachms and ten grains. No rise of temperature took place after the operation. The patient was usually drowsy, although he passed a large quantity of urine slightly tinged with blood. The variations in the temperature were carefully recorded by Mr. Whitehouse night and morning. On the evening of the 14th it had risen to 102°, and there was a little shivering, but it gradually fell to 98° on the 18th. The urine was slightly tinged with blood for thirty-six hours after the operation. A soft catheter was passed night and morning, and in about a week all dribbling had ceased. On Oct. 20th he first left his bed. The further progress of the case was uninterrupted, and he left the hospital on Oct 24th quite well. A month later the patient called at the hospital to say that he was quite well, and able to hold his urine.

Fig. 3.



Case 4. *Medium-sized uric-acid calculus in a paralytic man.* (Fig. 4).—John K——, formerly a farmer, seventy-two years old, was admitted into St. Peter's Hospital on Dec. 2nd, 1880, suffering from stone in the bladder. From notes taken by the house-surgeon, Mr. Neale, it appeared that for three years the patient had suffered from pain at the tip of the penis when making water, which he was obliged to do every quarter of an hour. For about two years he had

Fig. 4.



not been able to walk, and had suffered from partial incontinence of urine and loss of speech. There was a great deposit of mucus in his urine, which was alkaline, and of a specific gravity of 1022, it contained triple phosphates, but no albumen or casts. The patient had been a large well-built man, but the muscles of the lower extremities were very shrunken and flabby. The man and his parents were all natives of Suffolk. Dr. Althaus, who was kind enough to examine the patient for me, stated that he was suffering from "paralyis dementia, from chronic inflammation of the cineritious substance of the hemispheres." On Dec. 8th at 4 P.M. the man was put under the influence of ether by Mr. Knott. I introduced a Bigelow's lithotrite without having to incise the meatus externus, and seized the stone, which was apparently round, and one inch and three-eighths in diameter. The calculus was exceedingly hard, and I had great difficulty in breaking it up. I used fenestrated and flat-bladed lithotrites for the reduction of the fragments. A No. 26 (F.) evacuating tube was employed to remove the débris. The operation lasted fifty minutes. The bladder was sounded by Mr. Coulson, Mr. Heycock, and myself, but not a fragment could be found. The weight of the dried débris, as ascertained by Mr. Neale, was eight drachms and six grains. Hot poultices were applied to the abdomen, and as there was great smarting when making water a suppository of a quarter of a grain of morphia was administered. For three days after the operation the urine was bloody, but afterwards it contained only some mucus. The patient's recovery was retarded for a fortnight by œdema of the lungs, but he gradually improved and left the hospital on Dec. 29th, absolutely free from all pain, and having a certain amount of control over his bladder and rectum.

Portman-square, W.

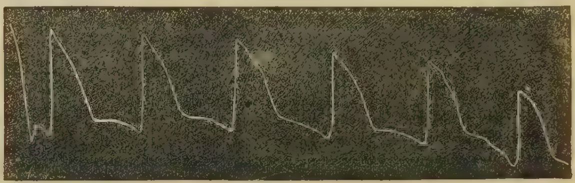
THREE CASES OF SUDDEN OBSTRUCTION OF THE ABDOMINAL AORTA BY ANEURISM; WITH REMARKS.[1]

BY J. S. BRISTOWE, M.D., F.R.C.P.

CASE 1. *Aneurism of lower part of thoracic and upper part of abdominal aorta, with complete obstruction of vessel on level of superior mesenteric artery; paraplegia; gangrene of feet; inflammation of bladder, with albuminous urine, &c.; death.*—T. D——, aged forty-two, a gardener, was admitted under Dr. Harley's care on the 31st March, 1880. He had followed his present occupation for a year, previous to which time he had for eighteen years been a railway guard. Five years ago he was laid up with "lumbago and gravel." A year and a half ago he had a severe shaking in a railway tunnel; and about a year since he had "rheumatism" in his back, and gave up work for seven weeks. In all other respects he was healthy and strong, but he has drank freely. He has had no pain or dyspnœa, and has been able to do hard work during the last six months. On the 27th of this month, while returning from work, he suddenly lost the use of his legs and fell down, but neither lost consciousness nor was giddy. Immediately before he fell a pain "took him like a flash of lightning" round the waist. This pain continued for an hour. By the time he reached home (an hour after the onset) he found that his legs were cold and without sensation. On the 28th he began to pass his evacuations involuntarily. Hot water was applied to his legs, and on the 30th bullæ appeared on the back of his thighs, inside the calves, and on the feet.

On admission he appeared to be a well-nourished healthy man. His face was not expressive of pain or anxiety. There were several superficial sores on the thighs, scrotum, and legs, due to the hot bottles that were applied before admission, and there was a huge shallow bedsore over the sacrum. He was in no pain, but complained of a sense of "deadness" in the lower extremities. There was complete paralysis of both lower limbs, with anæsthesia and loss of reflex excitability, and they were cold from the crests of the ilia downwards. No pulsation could be detected either in the abdomen or in the lower extremities. The heart's apex beat in the sixth interspace four inches and a half below and two inches outside the nipple; its action was heaving, and its sounds (which were free from murmur) were loud and ringing. The radial pulse was large and collapsing. Lungs healthy. There was no abdominal tension or tenderness. He passed his motions unconsciously. Urine alkaline, with a trace of albumen. Had frequent hiccough. During the next few days his general condition underwent little change. His appetite was fair, but he still had hiccough. His paralysis, anæsthesia, and incontinence of urine and fæces continued. But warmth gradually returned to the lower extremities from above downwards, so that by the fourth the only parts which remained actually cold were the toes of the left foot, and pulsation could just be detected in the course of the abdominal aorta. There was no return of pulsation, however, in the lower extremities, and the sacral bedsore was extending. The urine, moreover, continued alkaline, of about 1024 sp. gr., and contained much diffused blood and a quarter albumen, but no visible casts. On the 5th the temperature rose to 100·2°.

On the 6th of April he was still in much the same condition. His legs were fairly warm, but this was due mainly to their being thickly encased in cotton-wool. The toes were cold and cyanotic. His appetite was fair, but he was very thirsty, and still troubled with hiccough. His temperature was normal, his pulse 105, full and throbbing, and its trace much like that of aortic regurgitation. He had passed 46 oz. of urine during the night; smell of slough very offensive.



April 7th.—Slept well under the influence of morphia. This morning complained of pain in the back. Sensation extended to four inches below the iliac crests. Tongue thickly coated; no hiccough. Feet had become livid, more especially toes. A new bedsore had appeared on left buttock. In the afternoon he was for a time strange in manner, and partially unconscious. In the evening his temperature rose to 100·6° F., and his pulse was 132.

8th.—Rational; no particular change; temperature in the morning normal, in the evening 101·4°.

9th.—Complexion cadaverous, face sunken, and offensive odour from body; very drowsy. Has not had hiccough for several days. The sloughs on back, scrotum, and thighs are spreading. The toes are becoming more discoloured, and the left foot is blue and cold. Pulse 120, very weak. The temperature was 98·4° in the morning, and 100·8° in the evening.

10th.—Remained much the same during the earlier part of the day, his temperature being normal. But at 6.10 P.M. he had a rigor, lasting for ten minutes, during which his temperature rose to 102·8°. This was preceded by vomiting, and was followed by profuse sweating. Later in the evening his respirations were 48, his pulse 140.

From this time he gradually sank. He got weaker, and inclined to ramble at times. His pulse was rapid, feeble, and occasionally irregular, and the gangrene of his feet became more pronounced. His temperature went up once or twice to 101°, but it was more frequently normal or subnormal, and just before death it was 96°. He died on the evening of the 14th.

Post-mortem examination, April 15th.—Body emaciated; dry gangrene of toes and other parts of both feet; huge sloughy ulcer over sacral region. Head: Membranes of brain healthy; brain generally healthy, but a largish fairly recent hæmorrhage into left corpus striatum. Chest: Pleuræ and lungs healthy; pericardium healthy; heart enlarged; valves healthy and competent. Abdomen: Liver, spleen, stomach, and bowels healthy. Kidneys: right large, pale, and somewhat translucent; left smaller, but in same condition; both apparently healthy. Bladder much inflamed with tendency to slough. The aorta generally was atheromatous. Behind the heart and just above the diaphragm, at a distance of three inches from th cœliac axis, was a globular aneurism two inches and a half in circumference, arising from the back of the aorta, and communicating by an oval orifice an inch and a quarter long with that vessel. It had eroded the vertebræ, and was filled with old laminated clot. A second aneurism, as large, perhaps, as a filbert, involved the orifice of the superior mesenteric artery. This also was completely full of clot; and at this point the continuation of the clot into the aorta completely occluded that vessel, so that no water could be forced along it from above, either into the part below or into the superior mesenteric or left renal artery. The aorta between the two aneurisms was irregularly dilated, and three-fourths filled by a tough clot semilunar in transverse section, which was adherent to the posterior and lateral aspects of the vessel, and was continued into the clot which below obstructed the aorta. A somewhat sinuous channel remained in front leading from the aorta above the first aneurism to the cœliac axis and right renal artery, of which vessels the former was quite free, the latter was slightly obstructed. The trunk of the superior mesenteric was filled with adherent clot. The aorta below the superior mesenteric was empty and fairly healthy.

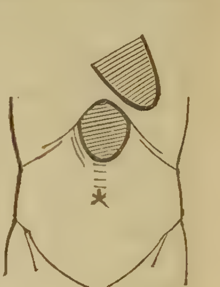
---

[1] A paper read at the West Surrey District Meeting of the South-Eastern Branch of the British Medical Association, held at Dorking on Thursday, Oct. 21st, 1880.

CASE 2. *Aneurism of aorta on level of cœliac axis and superior mesenteric arteries; complete aortic obstruction; partial paraplegia; suppression of urine, followed by albuminuria; congestion of kidneys and bladder; inflammation of rectum; death.*—B. D——, a policeman, thirty-two years of age, was admitted under my care on June 5th, 1880, at 8.40 P.M. He had enjoyed good health, with the exception that two years ago he had some pain in the lower part of the left side of the chest, which was supposed to be pleuritic. It lasted only a short time, and did not confine him to the house. He had never been subjected to ill-usage. On the morning of the day of admission he went on duty in Palace-yard, Westminster, at 6 A.M., and remained on duty till 10. He was then in his accustomed good health, with the exception that during the morning he had a slight attack of diarrhœa. After this he rowed to Wandsworth and back with a friend, then had dinner, and in the evening went for a walk. When close to the Elephant and Castle Railway Station he had a second sudden and severe impulse to go to stool, attended with a sense of coldness in the legs and flushing of the face. He ran up the stairs at the station to the closet, but he had some difficulty in doing this, for his legs were weak, and he was compelled to help himself by taking hold of the balustrade. He had a copious stool; but when he attempted to rise from the seat he found that he had lost completely the use of his legs, and he believes that he had lost feeling in them also. He called for assistance, and was at once put into a cab, and sent to the hospital.

On admission he complained of great pain at and within the anus. While in the taking-in room he seemed unable to move his legs; but when removed to bed he moved them slightly, and could bend them at the knees by voluntary effort. Sensation was impaired in them, they were cold, and no pulsation could be felt in them. A third of a grain of morphia was injected subcutaneously, soon after which he vomited. His temperature at this time was 97·8°. He had a very restless night, only sleeping for a few minutes at a time. His breathing was not unnatural, except that every now and then it became deep-drawn and sighing. He was sick after everything that was given to him, and complained of great thirst. Occasionally he had a return of pain at the anus, and at those times discharged a little blood, together with a small quantity of fæcal matter. He passed no urine; but at 10 A.M. on the 6th three ounces (all the bladder contained) were removed by the catheter. This had a specific gravity of 1020, contained no albumen, and appeared to be healthy.

I saw him for the first time at 1 o'clock the next day. He was a remarkably well-built, muscular, healthy-looking man. But he was evidently suffering from much anxiety of mind and bodily distress. Especially he complained of frequent severe pain at the anus, a gnawing pain down the muscles of both thighs (mainly the left), and abdominal tenderness. He could move his legs very slightly, and sensation in them was generally impaired. In some parts he could not feel the prick of a pin. But he had recovered both sensation and voluntary power in some degree since admission. The feet were cold, and no pulsation could be felt either in the arteries of the lower extremities or in the abdominal vessels. Neither could any abdominal tumour be felt. The heart's action was regular, 106 in the minute, and its sounds, which were free from murmur, were loud and ringing. The pulse was full and bounding. A well-marked murmur was audible over a limited area in the scrobiculus, and could be traced down to the umbilicus. It commenced with the systole of the heart, but was prolonged into the cardiac diastolic period, with some alteration of character. The respirations were not rapid, and every now and then were of a sighing character. The tongue was clean. The skin perspiring slightly. The temperature, which had been 100·9° about 9 A.M., was now 100·4°.—9 P.M.: Has vomited frequently since the last note, but the bowels have not been moved, nor has he passed any urine. He has had little pain, and is drowsy from the influence of morphia. Has some tenderness over seat of left femoral artery, but not over that of the right. No return of pulsation. Legs less cold to touch; natural in colour. The temperature has fallen to 98·7°.



June 7th.—Not much change. Restless, distressed, but no material pain. Constant sickness, and this morning a little hiccough. Tongue coated. The bowels have not been relieved. He passed a few ounces of urine during the night into the bed, and during the morning about an ounce was drawn off by the catheter. This contained three-quarters albumen, but no blood. There was visible pulsation in the brachials and carotids, but none in either femoral. Pulse 78; respirations 24. The temperature, which was 97·7° in the morning, rose to 99·1° in the evening. The surface temperature of the right thigh was 95·8° and of the left thigh 94·6°.

8th.—10 A.M.: Dozed during the early part of the night, and vomited after everything he took until 6 A.M., when it ceased. At that time his breath began to get short and gasping in character, and he commenced to expectorate a quantity of blood-stained mucus. Has had no return of hiccough. Bowels not open. But he passed six ounces of urine voluntarily into a vessel; this had a specific gravity of 1020, was alkaline, offensive, contained much albumen, and microscopically displayed pus-cells, phosphates, and bacteria; but no blood or casts were seen. At the time this note was taken his pulse was 72; his respirations 36, and somewhat gasping; he had occasional cough, with mucous expectoration; there was much crepitation over the front of both sides of the chest, mainly the right, which was also hyper-resonant; and he had pains in the chest. The legs were not apparently colder than other parts of the body; he could feel fairly well in them, and could move them pretty freely, but the right better than the left. — 1 P.M.: Much distressed; great dyspnœa; respirations 48; rattling in the throat; constant hacking cough, with expectoration of frothy, blood-stained, watery fluid; abundant moist crepitation over whole of front of chest; pulse 128; temperature 100°. Has passed three ounces and a half of urine, and a little blood from the bowels. He is very restless, and moves his legs freely.—2.30 P.M.: Face pale and livid; surface cool; temperature 96·8°; respirations rapid and sighing, and expectoration of blood-stained mucus continuous; much crepitation over both lungs; pulse 192, regular, but feeble. Complains much of pain in the rectum, and has passed a little more blood by stool. Quite sensible.

From this time he gradually sank, and died at 5 P.M.

Post-mortem, June 9th.—A well-built, muscular, healthy-looking man. Chest: Pericardium healthy, heart weighing seventeen ounces, uniformly enlarged, otherwise healthy; a little atheroma in thoracic aorta; old pleural adhesions; lungs very œdematous; some patches of broncho-pneumonia. Abdomen: Peritoneum healthy; liver, spleen, stomach, and bowels generally healthy. An aneurism rounded but somewhat lobulated in form, and measuring two inches and three-quarters in diameter, opening from the back of the aorta by an orifice one inch and a half long, the lowest point of which was opposite the cœliac axis. The sac of the aneurism wound round the right side of the aorta so as to project nearly an inch in front of it, and it extended down for about an inch behind so as to intervene between the aorta and the vertebræ. The aneurism was completely full of clot, and the pressure exerted by the part last referred to on the aorta immediately in front had completely flattened and occluded that vessel, so that water could not be forced past the seat of obstruction. The occluded portion of aorta included the superior mesenteric and both renals, the orifices of which were consequently totally obstructed. Direct communication between the cœliac axis and the heart still existed. The bodies of the adjoining vertebræ were eroded. Veins of rectum dilated, and general inflammation of the mucous membrane. Kidneys very large and much congested. Bladder: Some ecchymoses beneath mucous membrane.

(To be concluded.)

A CASE OF AXILLARY HÆMATOMA.

BY SURGEON-MAJOR K. M'LEOD, A.M., M.D.,
PROFESSOR OF SURGERY, CALCUTTA MEDICAL COLLEGE.

History.—Saroda, a Hindoo male, aged forty-five, was admitted into the first surgeon's ward, Calcutta Medical College Hospital, on the 16th of September, 1880, with a large tumour in his left axilla. Two months before he noticed a small swelling in his left axilla. It was soft, painless, and freely movable. It increased somewhat during the next fifteen days. At this time he made a journey of fourteen miles in a cart, and on his return home he observed that the tumour had somewhat shifted its position. He now consulted Surgeon G. C. Ray, who punctured the wound, and found that it contained blood. Dr. Ray, who persuaded him to come to the hospital for relief, furnished the following note regarding the history of the growth: "He presented himself about six weeks ago with a soft tumour filling up the left axillary space. I at first thought it to be of a fatty nature. It shifted its place in the course of a night to the back, the axillary tumour becoming smaller. This confirmed me in my diagnosis of a migrating fatty tumour. After two days the axillary tumour filled up again suddenly, in the course of a night. It had a soft, fluctuating feel. I then thought it to be a hæmatoma. It got tense, painful, and exerted pressure over the brachial plexus. Application of lead and opium relieved the pain, and the tumour hardened. It gradually got smaller in size, when again there was a sudden increase, and it doubled in size. Exploring with a needle brought only fluid blood. It has got harder since then, and is attended with some burning pain." The patient states that its growth during the last month has been very rapid. No history of injury of any kind can be elicited, and the man states that he has always enjoyed good general health.

Condition on admission.—The patient is a well-developed, stout, healthy-looking man. He has a large soft swelling in the left axilla. The tumour as large as a good-sized cocoanut, and occupies the whole of the axillary space, the floor of which is convex and bulged downwards. There is also a distinct bulging of the infra-clavicular and mammary regions, and the swelling extends as far as the axillary border of the scapula down to its inferior angle. The apparent swelling measures about eight inches vertically, and about a foot transversely. It is smooth and evenly globular, and the skin subcutaneous. Areolar tissue and pectoral muscles are freely movable over it. It is less movable deeply, and appears to be wedged in between the scapula and chest wall, and firmly fixed to these parts. There is distinct fluctuation; no pain, œdema, heat, pulsation, or bruit. It cannot be emptied by pressure. There is slight deficiency of sensation in the upper and outer half of the left arm, but no œdema of the extremity, nor impairment of muscular power, and the movements of the shoulder-joint are impeded to no greater extent than the situation and size of the tumour explain. The left brachial and radial pulses are normal. The tumour was explored by a fine trocar and cannula, through which a free flow of dark venous blood, apparently undergoing disorganisation, took place. The swelling was diagnosed to be a tumour containing blood; and as the man's general health was good, and the mass, as far as could be ascertained, distinct and separate from the surrounding parts, its removal was considered feasible and justifiable.

Operation.—On Sept. 19th an operation was performed for the removal of the tumour. The patient was chloroformed, and the removal conducted under strict antiseptic precautions. Measures were adopted, in the first instance, to command the circulation. A loop of six strong catgut threads was carried beneath the axillary vessels and brachial plexus by entering a Wood's hernia needle opposite the inner border of the coracoid process of the scapula, carrying it inwards along the lower border of the first rib, and making it emerge about an inch from the sternal end of the clavicle below that bone. It was ascertained, on depressing the handle of the needle, that the radial pulse was obliterated, the pulsation returning on removal of the pressure. The eye of the needle was threaded with three strong catgut threads, and these were pulled through its track, the six ends being knotted together and passed through the loop, and a pad of antiseptic gauze was placed between the noose thus formed and the skin to prevent nipping. By tightening this noose the radial pulse disappeared, and its management was entrusted to an assistant. An Esmarch's india-rubber cord was placed on the arm to command the venous circulation, and by these means the circulation of the region occupied by the tumour was thoroughly abolished, except in so far as it might be supplied by anastomosis from the pectoral and scapular regions. A long horizontal incision was now made along the lower border of the pectoralis major muscle, and another at right angles to it from its middle to the inferior angle of the scapula across the floor of the axilla. The surface of the tumour was thus exposed, and it was found to present a bluish colour, and to be capable of easy separation by the fingers from the surrounding muscles and fasciæ. The mass was in this manner enucleated as far as possible. In endeavouring to separate it posteriorly the finger broke through the cyst wall and a flood of venous hæmorrhage—the contents of the sac—was the result. The deep attachments of the tumour were now caught, tied firmly with stout catgut, and then divided. After the strongest and deepest of these, springing from the inner side of the apex of the axillary cavity, had been thus dealt with, it was found that the axillary vein had undergone division, and a catgut ligature was placed on its proximal and distal orifice. The subscapular vein also required a ligature. The tumour having been removed in this manner, except a small portion of the cyst wall in the angle between the subscapularis and serratus magnus muscles, which was scraped and left behind, the loop and india-rubber band were loosened and several bleeding points removed. The hæmorrhage from these was inconsiderable. The catgut loop was pulled from within the wound and left *in situ* to provide against possible secondary hæmorrhage. The ends of the ligature were utilised for drainage. Two fenestrated caoutchouc tubes were placed in the wound, the edges of which were accurately brought into apposition by iron wire and horsehair sutures. The wound was carefully dressed antiseptically. It was found that a thorough dissection of the axillary space had been made.

Progress and result.—There was considerable shock for several hours, succeeded by reaction, which gradually subsided. The temperature reached a maximum of 101° on the evening of the 20th, and became normal on the 24th. The wound healed by the first intention, except when the drainage-tubes and threads emerged. The tubes were removed on the 21st, the catgut loop on the 22nd, the catgut drain came away on the 27th and 28th, and the stitches were taken away on the same days. The discharge which came from the interior angle of the wound was found to be offensive on the 21st, and continued so for a few days. This seemed to be due to the sulphur in the tubes, for the rest of the wound remained sweet, and the whole of it underwent physiological repair in the same manner as wounds do under antiseptic treatment. Inflammation was absent throughout, and no pus appeared, except from one of the orifices of the loop, where the tissues had been nipped, and at the inner angle of the horizontal wound, where the knot of one of the ligatures caused irritation, and finally came away. The angles of the wound were firmly cicatrised on Oct. 20th, and the patient left hospital on the 22nd, with a thoroughly sound cicatrix. The axillary hollow was deeper than on the opposite side, and the movements of the shoulder somewhat constrained by the cicatricial contraction in the wound cavity. The left pulse was equal to the right. The innervation of the extremity was normal, and no œdema existed. The man's general health was thoroughly sound.

Description of the tumour.—The following description of the tumour, extracted from the museum catalogue, was written by Dr. J. F. P. McConnell, Professor of Pathology and Curator of the museum:—

"*Venous aneurismal sac removed from a Hindoo male, Saroda, aged forty-five.*—This sac or cyst is about the size of a fœtal head. A small portion of it was cut away during the operation (the rent has now been stitched), and at one part is a rounded opening capable of admitting the little finger, which is the orifice of communication of the sac with the axillary vein; the latter was above and below this spot on the separation of the tumour. The cyst contained only fluid blood—no coagula. On examining the interior there is found a layer of reddish grumous soft material, two to three lines in thickness, unequally distributed over the cyst wall; this material is easily scraped away, and consists of blood coagulum, showing no lamination or decolorisation, and presenting under the microscope only altered blood-corpuscles (broken up and shrivelled), with much dark amorphous pigment matter and some hæmatoidin crystals. When this material is scraped away, the inner surface of the sac or cyst is seen to be smooth and shining — i.e., has a distinct lining membrane, the flattened tesselated and nucleated epithelial cells composing which can quite readily be recognised under the microscope. The rest of the cyst wall consists of well-formed fibro-elastic tissue, with also smooth muscular tissue—in fact, it seems quite identical with the ordinary structure of the walls of a vein; so that there can be no doubt that the sac was an aneurismal-like expansion from the axillary vein, and is not an adventitiously formed cyst. There are no dissepiments or indications of such in the interior of the sac."

Remarks.—The ascertained history does not throw much light on the origin of this remarkable growth. The result of examination after removal points to its being a sacculated venous aneurism, springing and developing primarily from the axillary vein, and not a cyst, serous or angiomatous, which had somehow contracted a secondary communication with the veins. Assuming it to have been caused by a sacculated expansion of the vein, it must have existed in the axilla long before it was noticed. Its existence was probably discovered only when from its size the tumour began to bulge and press uncomfortably on the surrounding parts. Similar tumours are alluded to in the works of Paget and Billroth, but they appear to be rare, and their etiology is undoubtedly obscure. The present case deserves record on account of (1) the size which the cyst attained; (2) the evidence which is afforded of the nature of the growth, which appears to have been a venous aneurism; (3) the expedient which was adopted to prevent hæmorrhage; and (4) the successful removal of so large a tumour from so important a locality with so little disturbance, constitutional or local. This result I am inclined to attribute to the employment of antiseptic precautions (Listerism); and I venture to assert that so easy and complete a cure could not have been obtained in any other way.

Calcutta.

EXCISION OF THE WHOLE TONGUE BY THE GALVANIC ÉCRASEUR.

BY F. A. PURCELL, M.D.,

SURGEON TO THE CANCER HOSPITAL, BROMPTON.

IN THE LANCET for July 5th, 1879, I described the operation "for the painless and bloodless method of excising the whole tongue," affected with epithelial cancer. I need not go over the same ground again, but suffice it to say that I have had no reason to deviate in the slightest degree from the operation I there described; I have performed it several times since successfully, but it may be interesting to record a case in which a fatal result has taken place.

On Oct. 12th T. C——, aged thirty-eight, suffering from epithelioma of the entire right side of the tongue, ulcerated, with ichthyosis extending into the opposite side. Glands only slightly enlarged in the submaxillary region. It was decided to remove the entire tongue by the galvanic écraseur. The patient being put under the influence of the anæsthetic I introduced the nozzle of the cannula through a vertical submental incision (after Nunneley) into the floor of the mouth, and, proceeding exactly as I have previously described the operation in THE LANCET of July 5th, 1879, excised the whole tongue, having got well behind the disease. The patient came to without losing during the operation any blood. The submental incision was brought together by one horsehair suture, and he was removed to his bed. Within two days he was up and about the ward, and on October 19th I examined his mouth and found the root and floor of the mouth beginning to show granulations and the slough detaching itself; all seemed well; however, during our operations, the house-surgeon was requested to see him, as he had some hæmorrhage (now eight days after operation). He went to him, and applied some ice and iron solution, which seemed to restrain it. Hæmorrhage again recurred about eight o'clock. The amount was so profuse that our house-surgeon, Dr. Bourns, thought it wise to send for me. I arrived and found my patient very exhausted, with a very feeble pulse, and a clot of blood, blackened from the solution of perchloride of iron that had been applied, hanging out of his mouth, conscious and able to write his wishes and requirements on a slate. Although hæmorrhage seemed to have ceased, I thought it wise to ask for a consultation of my colleagues, who all arrived at the hospital about 11 o'clock P.M. We still found him in the same condition as before described. The advisability of tying the linguals, which should have been done on both sides, was deferred, and instructions to leave the clot *in statu quo*, and feed the patient by enemata of beef-tea and milk, with a half-drachm of tincture of opium every second hour, as also to exercise digital pressure on the carotid of one side first if any hæmorrhage should again appear, and if this did not stop it to try the same on the carotid of the other side. Fortunately the patient passed the night without the recurrence of the bleeding. During the next few days the mouth was left untouched, and the same enemata assiduously continued.

On the 22nd the mouth was cleansed, and he took some iced drinks, much to his relief, cold tea, and nourishing drinks; the tincture of opium was not discontinued. On reflecting light by means of a looking-glass into his mouth, the slough is observed to be detached, and the red granulations appearing. He talks now fairly well, but cautioned not to do so. His pulse has regained its beat; in fact, his heart, which has a systolic murmur with violent palpitation, troubles him much, so that he is ordered a mixture of solution of perchloride of iron and tincture of digitalis every four hours, cold drinks and nourishing enemata every four hours. All seemed favourable towards recovery.

On the 23rd the patient, having discontinued the laudanum in the enemata, did not sleep so well during the night, but otherwise much improved. Diarrhœa set in during the afternoon.

Oct. 24th.—The patient now refuses his food, and is troubled with violent palpitation of the heart, the floor of the mouth granulating nicely, and looks clean. He remained in this condition until he died on Tuesday night, the 26th of October, fourteen days after the operation. He suffered from an aortic and mitral murmur, with a very rapid small pulse. At the same time the heart palpitated violently.

The heart alone was removed after death, and showed great hypertrophy and dilatation of the left ventricle, with incompetent aortic and mitral valves.

Manchester-square, W.

RUPTURED SPLEEN FROM A FALL.

BY HENRY TOMKINS, M.D.,

MEDICAL OFFICER, MONSALL FEVER HOSPITAL, MANCHESTER.

RUPTURE of the spleen, though not of very uncommon occurrence, is yet sufficiently rare to warrant the following case being placed upon record, the more so as it presents one or two features peculiar to itself—firstly, the fatal issue did not take place until three weeks after the receipt of the injury; and, secondly, so little importance was attached to the injury that at the time of death suspicion was aroused that the patient had died from the effects of medicine obtained from an unqualified practitioner.

On Oct. 21st, by order of the coroner, a post-mortem examination was made on the body of Mary M——, aged twenty-five, unmarried, who had been found dead in bed ten hours previously. The body was fairly nourished; no external marks of violence, but very anæmic; lips, conjunctiva, &c., quite bloodless. The abdomen was somewhat distended; dull on percussion. On opening it the peritoneal cavity was found filled with dark sanious fluid and numerous large soft clots. Beneath the edge of the ribs on the left side, extending across the epigastrium, was a huge dark mass, which proved to be the spleen. In size, speaking roughly, it was as large as the liver, and weighed at least four pounds, probably more. On the under-surface the organ was ruptured, and on cutting into it, it was found to be hollowed out into a large cyst filled with soft coagula. All the other organs of the body were healthy and bloodless.

The history given was this :—Three weeks before she had been standing on a box some three feet high, from which she fell, striking her left side against a corner of it. She complained at the time of having hurt herself, but not severely, and in a few minutes after resumed her work. From that time onward she complained more or less of her side, saying it "caught her breath," and that she felt as if she had "a lump there," but her friends could detect nothing abnormal by sight or touch. There was no bruising after the fall.

The night before she died she complained still more of the pain, referring it chiefly to the epigastrium, and called that evening on an unqualified practitioner, who gave her some medicine, of which she took about an ounce and a half, went to bed, and was there found dead the following morning.

At the inquest the medicine was proved to be only a simple antispasmodic mixture.

The blood was unfortunately not examined, so that it is somewhat uncertain whether this was a case of leucæmia; no glandular enlargement was detected, and the previous history pointed to good health, but impoverished circumstances, and shortness of food. If the spleen were normal in size at the time of the accident, the above is certainly a very unusual case. The length of time also that elapsed between the receipt of the injury and the fatal termination is much longer than any I can find recorded.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium

GREAT NORTHERN HOSPITAL.

A CASE OF TELANGIECTASIS.

(Under the care of Mr. GAY.)

A VERY remarkable case of this disease was admitted during the last summer. The patient was a girl eight years old, otherwise healthy. The disease was an entirely new growth, and consisted of a cluster of distended veins so convoluted and coiled on each other as to form a compact venous tumour. It occupied the whole of the right side of the cheek, and seemed to be a teratological development of the venous at the expense of the muscular elements, especially that of the buccinator muscle; for before the growth of the tumour the muscular tissue receded and disappeared; so that the tumour bulged outwards on the cheek very considerably, showing its blue colour in patches through the skin, which was extremely thin. On the inner side of the cheek it also bulged as a closely packed mass of large convoluted veins, which at length protruded so far as to incommode the child in talking and masticating by getting between the teeth. From the cheek the growth extended in a broad and irregular band across the back of the mouth and the hard palate, the mucous membrane of the entire half of which was thickened and discoloured by it, and to the lower lip, the half of which was also occupied by large veins, which exalted themselves considerably above the normal level. The tumour on the cheek was defined and impressible, so that the blood could in great part be expressed from it, but not without leaving behind a considerable amount of dense doughy material, that consisted no doubt of the thickened walls of the veins and their intervening connective tissue; and that the whole was enclosed in some tough limiting envelope there could be no doubt, for on expressing the contents and instantly relaxing the pressure, the blood rapidly distended the mass again, but the latter did not exceed its ordinary limits.

The mother could give no trustworthy history of the tumour, but it was unquestionably of congenital origin, and allied to the ordinary nævi of this class. It seemed to have the ordinary supply of nerves and arteries, for its sensibility and temperature were normal, and none but the usual arteries or veins could be found in any part of the healthy bordering structures. The mass was growing but had not bled spontaneously.

After discussing several plans of treatment, and notwithstanding the fact that cauterisation by red-hot needles had been tried elsewhere without any appreciable result of any kind, Mr. Gay determined to cauterise by means of large blunt needles made red hot by benzine vapour.

The child having been placed under the influence of chloroform by Mr. Eastes, the portion of the cheek containing the tumour was thrust out of the mouth as far as possible. The mass having been in this way fairly exposed, Mr. Gay pushed a thick red-hot needle, a line in breadth, deep into the tumour at several points. The blood was not squeezed out of the mass before the needle was used because it was feared that though the cautery would seal the openings in the vessels the needle had made, the reflux of the blood would reopen them, and bleeding would ensue. No bleeding took place, although the openings were as large as a six- or seven-sized catheter. The whole tumour immediately swelled, but subsided again after the escape of a quantity of bloody muco-serous fluid from the burnt aperture and mucous membrane. The results, however, were not satisfactory, for after the healing of the wounds the tumour was left much as it was before the operation. After an interval of three weeks Mr. Gay determined on repeating the cauterisation, but confining the punctures to a limited portion of the swelling. He therefore selected the most vascular portion, and made five punctures within an area of about three-fourths of an inch square. On withdrawing the needle two of these punctures bled copiously, throwing out jets of dark with some crimson blood of the same size as the orifices. The bleeding was, after trying several futile plans, ultimately stopped by passing ligatures deep into the tissue below the bleeding parts, by means of an eyed tenaculum, armed with thick silk, and tying them across the apertures. This procedure was followed by consolidation of the whole of the portion of the tumour that had been brought within its scope, but beyond this the tumour was as active as before. It then became clear that complete obliteration of the mass could only be gained by a series of similar procedures, each being limited to a small portion only of the diseased mass. A portion was now selected full of large vessels nearer the back of the mouth, between the cheek and the palate, and three punctures were made in it. Again the bleeding was very profuse, and as there was some difficulty in using ligatures Mr. Cripps suggested that the openings should be forcibly plugged with lint moistened with the solution of perchloride of iron. In this way the bleeding was stopped, the plugs being allowed to remain until released of themselves. Suffice it to add that the united portion of tissue that was thus brought under the influence of the cautery solidified, but no more, and that it required several other like operations to bring the whole into a like condition. The portion that passed across from the cheek to the palate was exceedingly troublesome, and required several applications of the cautery, each of which was followed by profuse hæmorrhage. Eventually, however, every portion seemed to have succumbed, and the vascular tissue was reduced to a consolidated mass, first of clot and vessels, and ultimately of compact nævoid tissue, minus its blood. Such was the vital tenacity of the growth that the large outlying veins on the lip had to be ligatured in order to bring about their consolidation.

The child presented herself at the hospital a week ago. By far the largest portion had consolidated, but not the whole. There was an island just within the mouth, and another at the extreme back part of the cheek, which presented not only large venous coils, but were in a state of growth. These will require at no distant period the renewed use of the cautery. Mr. Gay prefers the cautery to other modes of treating these nævoid tumours, but he would feel little hesitation in the event of such treatment being unsuitable in a given case to extirpate it by the ordinary knife, or, if found necessary, by red-hot knife, for the supplying artery as well as the receiving veins did not appear to be of abnormal distribution or size.

CLAYTON HOSPITAL, WAKEFIELD.

CASE OF GLOSSITIS.

(Under the care of Mr. Fowler.)

For the following notes we are indebted to Mr. R. L. Williamson.

William H——, aged thirty, was admitted on July 17th with glossitis. The tongue was protruded two and a half inches beyond the teeth, and could not be retracted. The whole organ was very greatly enlarged and of a brawny hardness, due to exudation. A deep ulcerated fissure existed where the tongue rested on the lower incisors. There was difficult, hurried respiration, the breath was fetid, and saliva constantly dribbled from the mouth. Only fluids could be swallowed, and these with difficulty. The dorsum of the protruded portion of the tongue was parched. The patient said the affection began twenty-eight days before, that he was nearly suffocated at first, and that an abscess had formed at the root of the tongue, and burst with only slight relief of the symptoms a week from the commencement of the attack. On admission the temperature was 101° F.

The mouth and all its contents were thoroughly cleansed with a strong solution of chlorate of potash in glycerine and warm water, and a piece of lint frequently wetted with water was kept over the protruded part of the tongue. The mouth was frequently syringed out. No perceptible improvement followed. Four days after admission a gutta-percha support was made for the tongue, and fitted to the lower incisors. This afforded great relief to the patient, and the exudation began to disappear rapidly, so that forty-eight hours afterwards he could retract the tongue within the teeth, after being unable to do so for more than a month. The fissure caused by the pressure of the lower incisors simultaneously disappeared. The patient shortly afterwards could keep the tongue within the teeth permanently, and the case progressed so rapidly that a week from the time the gutta-percha support was first used he was almost well. He was discharged cured seventeen days after admission.

He had not had syphilis nor had he the characteristic signs of scrofula, though this affection, accompanied by abscess, generally occurs in scrofulous subjects. The case is unusual in that the exudation did not tend to disappear after the evacuation of the abscess. It would seem that this persistence of the exudation was due to hyperæmia of the organ, caused mechanically by the pressure of the teeth.

ROSS COTTAGE HOSPITAL.

LOOSE CARTILAGE IN KNEE-JOINT; REMOVAL.

(Under the care of Dr. C. C. Cocks.)

H. G——, aged forty-two, was admitted on Sept. 1st, complaining of pain in his right knee-joint, which had troubled him at times for twelve or eighteen months. On examination a loose cartilage was easily felt. Removal of the body was advised.

On Sept. 2nd, chloroform having been given, and with strict Listerian antiseptic precautions, an opening was made on the outside of the knee-joint, about an inch and a half long, through which a loose cartilage, weighing three drachms and a half, was easily removed.

The patient made an uninterrupted recovery, and was up on the twenty-first day, and at the end of eight weeks followed his work as a labourer.

After removal the substance was examined, and found to be made up of an oblong flat piece of bone-like material, with a thick corrugated fringe of cartilage all round.

Lincoln County Hospital.—The annual meeting of the Board of Governors of this institution was held on the 13th inst. The financial statement showed the receipts during the past year to be £4295 4*s.* 1*d.*, and the expenditure £5565 1*s.* 7*d.* Various propositions were made to remedy this unsatisfactory state of things, but ultimately it was decided to issue a special appeal to well-to-do persons in the neighbourhood who were not already subscribers—a step which we hope may meet with the success desired.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Acute Myositis.—Abscess of Liver.—Cirrhosis of Liver and Tuberculosis.—Thrombosis of Innominate Vein.—Stenosis of Tricuspid Orifice.—Fibro-cyst of Uterus.

The ordinary meeting of the Pathological Society of London was held on Tuesday last, Dr. Wilks, the newly-elected President, in the chair. There was a very small attendance of members. On the motion of Dr. Pye-Smith, seconded by Mr. Morrant Baker, the President was requested to postpone his introductory address until the next meeting, as there were many members of the Society anxious to hear it who were prevented from being present by the extremely inclement weather. Dr. Wilks consented to this proposal, and the ordinary business of the Society was proceeded with. In addition to other communications of interest, Dr. Fenwick made a careful and valuable communication on Stenosis of the Tricuspid Orifice of the Heart.

Dr. Payne showed a specimen of Acute Myositis, and read an account of it, sent to Dr. Greenfield by Dr. Bevis, of the Hereford Infirmary. A woman, aged thirty-three, three days after her confinement got up and went downstairs into a cold room, where she had a shiver, and on attempting to return to bed found she had to crawl on hands and knees, on account of severe pain in the right thigh. The pain increased for the next two days; and on the third day there were tenderness, rapidly increasing swelling, and redness of the skin. She was then admitted to the hospital. She had chills, but no sweats; temperature about 100·4°; pulse 132; tongue dry, with sordes on the lips; no cardiac bruit. The right thigh was much swollen, hard, brawny, very tender, hot, and there was pitting on pressure. Next day the pain was less; there was great tremor, and she died. At the post-mortem the bone and periosteum were healthy. A section of the muscles showed the vasti and crureus to be yellowish in colour, resistant, the fasciculi separated so as to present a granular surface, the fibrous septa being infiltrated with serum. The fibres of the vastus externus were found to have lost their striæ, and to contain granular débris and very few cell elements. The adductor magnus muscle had its striæ well marked, with many cells, and both red and white blood-corpuscles. The rectus femoris was healthy.

Dr. Norman Moore showed a specimen of an Abscess in the Left Lobe of the Liver in a girl, aged three years and a half, who died in St. Bartholomew's Hospital. She had been ill ten months with intermittent diarrhœa and pains in the belly. During her stay in the hospital her temperature varied from 102° to 105°; at the end of a month she died from sudden collapse. After death this abscess at the surface of the left lobe and another larger one in the substance of the right lobe of the liver were found. The whole of the large intestine was extensively ulcerated. The points of interest in this case were the early age of the patient, and the fact that the child had never been out of London; although he had known of dysentery occurring in Londoners, he had not been able to meet with any case occurring in so young a child.

Dr. Norman Moore also showed microscopical sections of a Liver affected with Cirrhosis. A girl ten years of age, under Dr. Gee's care at St. Bartholomew's Hospital, had enlargement of the belly for some time; she was tapped twice for the ascites. At the autopsy the whole liver was found to be dense, with great elastic bands of fibrous tissue running through it, rough and nodular; there was tuberculosis of the peritoneum, but none of the liver. There was no history of spirit-drinking, and Dr. Moore thought this was an example of interstitial hepatitis in association with general tuberculosis, as described by Cornil and Ranvier, and more fully by Dr. Payne.—The President asked if the patient had the usual appearance of patients with cirrhosis of the liver, and whether the diagnosis was made.—Dr. Moore replied that the child was very emaciated, and with a big belly; after one of the tappings it was noted "liver certainly not enlarged."—Dr. Pye-Smith had recently a young man under his care at Guy's Hospital with great ascites and no symptoms of any lung affection; he was tapped two or three times, and eventually died. Slight cirrhosis of the liver, with considerable tuberculosis of the peritoneum and right pleura, were found. The diagnosis was difficult; he had thought the ascites due to cirrhosis of the liver from drink, but now had no doubt it was occasioned by the inflammation of the peritoneum.—The PRESIDENT asked for information on the collateral circulation of the liver. The enlargement of the superficial veins of the belly had been long noticed and variously explained, and he had read that it had been shown by German observers to be connected wieh enlargement of vessels in the suspensory ligament of the liver, and particularly with reopening of the obliterated umbilical vein. It would be very interesting if any member could demonstrate such a condition, which would be best done by injection from the portal vein. If this be the correct explanation, the blood circulating in the dilated vessels is portal blood, and possibly that could be demonstrated by microscopic examination. There must be a very free collateral circulation in some cases, for with extreme cirrhosis and narrowing of the portal vessels there may be no ascites.—Dr. N. MOORE mentioned the case of a woman who, thirty years ago, had severe hæmatemesis, which was repeated from time to time, until recently during an attack in St. Bartholomew's Hospital she died. There was found complete occlusion of the portal vein, the spleen was greatly enlarged, no ascites; Dr. Gee could not find any opening out of the obliterated umbilical vein, showing that this was not the sole collateral circulation.—Dr. STURGE stated that two years and a half ago he had under his care a man with cirrhosis of the liver, with not very marked ascites, who had a well-marked caput medusæ at his umbilicus, and a vessel as large as his forefinger running upwards from it to the sternum. During life it was doubtful whether the swelling contained blood or serous fluid, but he inclined to the former view. The ascites disappeared, and he saw no more of the man till three months ago, when he heard of his death. He made an examination, and found a vein large enough to admit his little finger passing from the portal vein through the suspensory ligament, a vein in the round ligament as large as a probe, and others intermediate in size between these two around the ligament. All these veins entered the caput medusæ, from which the large veins seen on the surface passed to the internal mammary vein.—Dr. GILBART SMITH had under his care now a man with phthisis affecting the left apex, and irregular enlargement of the liver; there is very little fulness of the abdomen, but the veins passing from the umbilicus to the chest are distinctly enlarged; he thought this was a case of tubercular peritonitis, with cirrhosis of the liver.—Dr. PAYNE thought the case of his that Dr. Moore referred to was one in which many small fibroid nodules were found in a liver, possibly tubercular. He had many times injected the portal vein in cases of cirrhosis, and had sometimes found a vein running up the round ligament, but never the whole way, and many other veins running from the liver to the umbilicus outside the round ligament. This collateral circulation was first described by Sappey. Dr. Champneys had published in the "Journal of Anatomy" a description of a case of reopening of the umbilical vein. There are also many other anastomoses of the portal and systemic veins in the peritoneal cavity.—Dr. O'CONNOR mentioned the case of a woman who, when she lay on her face, had no œdema of the feet, but the superficial veins of the belly became distinct; but when lying on her back the veins were empty, and the legs became œdematous.

Dr. WILBERFORCE SMITH brought forward a specimen of Thrombosis of the Right Innominate Vein. It was removed from a woman forty-two years of age, who had some severe respiratory affection ten years ago, which left her subject to cough. Eight months ago she had a transient attack of dropsy, commencing in the left arm, and two months ago another attack of dropsy, which commenced in the feet. Four weeks later he found she had great swelling of the right arm up to two inches below the shoulder, lividity with enlarged superficial veins of the right side of the head and neck, œdema over the right side of the chest, dulness at the right apex, especially at the inner side. The case had then the appearance of serious cardiac disease, but there was no orthopnœa. At the autopsy several pints of fluid were found in the right pleura. The right innominate vein was occluded by firmly adherent partially organised clot, which extended into the superior vena cava, and the ends of the subclavian and jugular veins were contracted and full of soft clot. The pleura was very thick and adherent to the apex of the lung and to the thrombosed vein. In the apex of the lung was a cavity, but no other disease. In the right side of the dilated heart were two or three smooth old clots the size of orange pips. The order of events he believed to have been—1. Respiratory affection. 2. Dilatation of the heart, and weak circulation. 3. Thrombosis favoured by the languid circulation, and especially by the thickening and adhesion of the adjacent pleura.—Dr. COUPLAND had seen the post-mortem examination in this case, and agreed with Dr. Smith's view. He asked if this form of thrombosis is common; if not he was surprised, as the pleura is so near the veins and so often inflamed. The pleura in this case was very firmly adherent to the vein.—Dr. T. C. WILLIAMS had often seen thrombosis of the lower extremities in phthisis, but seldom, if ever, in the neck.

Dr. FENWICK showed two specimens of Stenosis of the Tricuspid Orifice of the Heart. The first case occurred in a single female-servant, aged twenty-nine, who had very good health till eighteen years of age, when she had an attack of acute rheumatism. Four years afterwards when carrying a very heavy child she was seized with severe pain in the side and great dyspnœa, which passed off under rest. Five years later she entered the London Hospital for jaundice, and was found to have a loud presystolic murmur, most distinct at the apex, and a soft whiff at the base. She had two other attacks of acute rheumatism, and after the last a harsh systolic murmur at the base was detected; and last autumn, when under Dr. S. Fenwick's care at the hospital, there was a harsh presystolic murmur distinctly audible at the xiphoid cartilage, apex thrill, great distension of jugular veins, œdema, and orthopnœa. After death the heart was found greatly dilated, especially the right auricle; the tricuspid valve agglutinated by the edges of the cusps, which were also thickened, and the orifice narrowed; mitral valve also thickened. The other case was also under Dr. S. Fenwick's care: a girl, aged twenty-six, single, enjoyed good health up to the age of twenty-three, then had acute rheumatism and ever afterwards dyspnœa, cough, and palpitation; harsh presystolic murmur at apex, presystolic thrill, tumultuous cardiac action with throbbing of the whole side; soft systolic murmur at base, great orthopnœa, cough, and ascites. The heart was found to be very dilated, especially the right auricle, mitral cusps thickened, rough, and adherent; tricuspid valve agglutinated, with only a very small aperture; pericardium adherent. From a review of forty-six cases of tricuspid stenosis recorded since 1825 he gleaned the following facts: That the disease is not excessively rare, as seven are recorded in the Transactions of the Pathological Society and eight in the Transactions of the Pathological Society of Dublin, and three had recently occurred in Dr. S. Fenwick's practice at the London Hospital. Forty-one of the patients were females to five males—a preference for the female sex not shown by congenital disease of the heart, for of thirty-one of such cases shown to this Society, seventeen were in the male and fourteen in the female sex. The youngest female was seventeen, male twenty-one, oldest female fifty-eight, male sixty-four; average duration of life in the females 31 years, in the males 36·4 years. In Dr. Peacock's case of congenital or tricuspid stenosis, which lived only three months, the child was perfectly livid from birth, and became black on coughing; but in only one of these forty-six cases was dark colouration noticed during early life, and the health was good until the fatal illness came on. Thus there are many facts opposed to the view of the congenital origin of this form of disease. In twenty-three cases there is a history of antecedent acute rheumatism, and such a history was obtained in one hundred and fifty-two out of three hundred and four cases of all cardiac diseases, the same proportion. In all the forty-six cases the mitral orifice is also stenosed, and in nearly all more diseased than the tricuspid; in twenty-five cases the aortic valves are diseased too, in twelve cases stenosis; in all save a very few the right auricle is greatly dilated. He therefore maintained there is positive evidence of its being an acquired disease.—Dr. N. MOORE had found thirteen cases of this disease recorded at St. Bartholomew's Hospital, and they bore out completely Dr. Fenwick's views. Twelve of the patients were females, the youngest nineteen, general age thirty; in all mitral disease; in nine aortic disease; and in one disease of all the other valves. In one only was there any trace of congenital malformation, a partial septum across the right auricle. Thus there was evidence that in these cases the endocarditis was general rather than local, and tended to adhesion rather than outgrowth and pucker-ing of the valves.—Dr. **GILBART SMITH** asked if cases of double stenosis live longer than those suffering from mitral stenosis only, because the double obstruction might save the heart and pulmonary circulation and regulate the distribution of the blood.—Dr. **HORROCKS** observed that in congenital mitral stenosis the left auricle does not hypertrophy sufficiently to overcome the obstruction and so carry on the general nutrition, and the patients look younger than their age. Were any recent vegetations found on the valves in Dr. Fenwick's cases?—Dr. **COUPLAND** thought the question was as to the etiology of mitral disease, because it was always present in these cases; mitral stenosis is more common in females; in some cases there is no history of acute rheumatism to be elicited. He had found vegetations on the tricuspid valve more common in acute rheumatism than supposed, but never present without being also on mitral valve.—Dr. **STURGE** recently made an autopsy in which he found two cusps of the aortic valve agglutinated together, all the cusps being uniformly thickened; the mitral valve was in the same condition, and he thought this case supported Dr. Moore's view of their being a special agglutinative form of endocarditis.—The **PRESIDENT** reminded the Society of some Gulstonian lectures of the late Dr. Barlow, in which he pointed out that disease of the right side of the heart, lessening the blood on the left side, caused imperfect growth on that side, and the mitral orifice remained small. Presystolic murmur over the xiphoid cartilage was taught as the sign of tricuspid obstruction, but he knew of no case on record where by this sign it had been actually diagnosed.—Dr. **FENWICK** had not observed any marked relation between double stenosis and duration of life. In neither case were there recent vegetations. He had recently seen very numerous vegetations on the tricuspid valve; they were present on the mitral valve also. Both his patients were well nourished and fully grown; in his table two only are mentioned as stunted.

Mr. **MEREDITH** showed a recent specimen of a large Multilocular Fibro-cyst of the Uterus, removed three days previously by Mr. Thornton from a patient in the Samaritan Hospital, aged forty-three. The existence of uterine fibroid disease had been first recognised ten years ago, but only within the past three years had the tumour, which up to that time had apparently presented the usual features of an ordinary fibroid growth, begun to enlarge at all rapidly. The total weight of the mass removed was twenty-three pounds, of which the fluid contents constituted about eighteen pounds. On examination the main portion of the tumour was seen to have consisted of smooth walled cystic cavities, eight to ten in number, and of varying capacity, seated on a solid base, which sprang from the fundus of a much enlarged uterus, by an extremely thick pedicle, partly fibrous, partly fleshy in structure. This pedicle at the operation was divided by means of Paquelin's blunt cautery knife. The cyst contents in most of the cavities consisted of a perfectly clear limpid fluid, of a deep amber colour, which did not coagulate spontaneously on subsequent exposure. Its sp. gr. was 1020, and on boiling a dense coagulum was formed, which proved to be incompletely soluble on being heated with an equal quantity of strong nitric acid. The microscope showed but few cell elements of any kind; among these were a number of large granular cells, resembling those found in ovarian fluids, a few squamous epithelial cells, and occasional examples of the so-called "fibre-cell," which is said to be characteristic of the fluid contained in these fibro-cysts.

The Society then adjourned.

CLINICAL SOCIETY OF LONDON.

Traumatic Hydronephrosis.—Myxœdema.

THE annual general meeting of this Society was held on the 14th inst., Dr. E. H. Greenhow, F.R.S., President, in the chair. The usual business was transacted during the first part of the evening, after which the election of officers, the reception of the Council's report, and the customary votes of thanks to the retiring officers took place. Two papers were read—one on a case of hydronephrosis of traumatic origin, cured by repeated tapping, by Mr. Croft, and one on two cases of myxœdema, by Dr. Lloyd. The latter paper excited some discussion, Dr. Andrew Clark relating his experience of the affection, which he stated he had met with most frequently in males. Drs. Dowse and Mahomed were appointed scrutineers of the ballot.

Mr. **CROFT** read a paper on a case of Traumatic Hydronephrosis. The patient, a lad aged twelve, was admitted into St. Thomas's Hospital on June 3rd, suffering from hæmaturia, with pain in the left loin, following an injury to the left side received on the previous day. There was no swelling, but there was deep-seated tenderness in the loin. The urine had a dark port-wine colour from admixture with blood. The boy was delicate and anæmic, and was the subject of psoriasis. Under treatment by rest in bed and the local application of ice, the hæmaturia gradually subsided, and on the fourteenth day from the accident he was discharged as convalescent, no tumour having appeared. On July 9th—twenty-two days after he left the hospital—he was readmitted, suffering from a swelling which had appeared in the left side. The swelling occupied the left lumbar and hypochondriac regions, and extended forwards into the epigastric and umbilical regions. It was fluctuating, but there was no redness of skin over it. The urine was free from blood, and of normal specific gravity. During the next two days he became worse; the swelling increased, extending across the median line, and he became drowsy, the temperature falling below 100°. The urine was still free from blood or albumen, its quantity varying from fourteen to twenty ounces. The case being thought to be one of hydronephrosis, an aspirating trocar was passed into the swelling, and seventy-nine ounces of brown, urinous fluid, acid, sp. gr. 1008, and containing a trace of albumen, were drawn off. During the next three days he passed twenty-five ounces of urine each day, and on the fifth day twenty-one ounces. There was immediate relief after the tapping, but at the end of a week a re-accumulation of fluid necessitated a second tapping; which was repeated for the second time nine days later, when sixty-two ounces of similar fluid, acid, sp. gr. 1005, and containing a trace of albumen, were withdrawn. Between July 29th and October 15th the swelling was tapped five times; and on the last occasion the fluid contained much albumen, since when no further collection has taken place. There had been no constitutional disturbance, and no sudden variation in the quantity of urine passed. Mr. Croft thought that there had been a severe contusion of the pelvis of the kidney, followed by adhesive inflammation and obliteration of the ureter, which led to accumulation of the urine in the pelvis and the formation of the hydronephrosis. The case could not be one of a congenital cyst which had enlarged in consequence of the injury, for such a cyst would contain serous fluid. The cure probably took place by obliteration of the sac and atrophy of the kidney. A similar case is recorded by Mr. Stanley in the Med.-Chir. Trans. for 1844, where six weeks after an injury to the right side a large swelling appeared from which fifty ounces of urinous fluid were drawn off. The tapping was repeated at intervals, only six ounces being withdrawn at the final tapping, and the patient left the hospital at the end of nine months with a fluctuating swelling still present. A second case recorded in the same paper appeared rather to be one of retro-peritoneal extravasation of urine. The present case showed the value of repeated tapping by the aspirator.—Mr. **HEATH** thought Mr. Croft's explanation hardly accounted for the complete disappearance of the swelling. Might not the hydronephrosis have been due to an impacted calculus? The accident might have shaken a calculus into the pelvis, where it would have caused an obstruction to the outflow of urine, and the repeated tappings might have caused the dislodgment of the calculus. Were there any bladder symptoms, and does the patient now pass a normal quantity of urine?—Mr. **CROFT** said the idea of calculus had occurred to him, but his inquiries failed to elicit any confirmation of this view. As the tumour subsided he passed a normal quantity of urine. If a calculus had been dislodged there should have been some symptoms of it in the bladder.

Dr. **LLOYD** read notes of two cases of Myxœdema, one of which was shown to the Society. Case 1.—A female, aged forty, whose mother had been subject to rheumatism. She menstruated regularly. Five years ago she experienced severe pain in both her legs, and then all her movements became slow and deliberate. She also suffered from pain in the head, and her face became puffy. Three years ago she began to complain of weakness in the neck, which was painful; her voice became rougher, her memory impaired, and her expression listless. There seemed to be general swelling of the skin all over the body, and especially puffiness of the eyelids. The skin, which was dry and rough, never perspiring, had a translucent œdematous appearance; and she came to present the characteristic aspect of the disease in the heavy puffed features, with congested cheeks contrasting with rest of face, which was void of expression. Her voice is thick and nasal. She is low-spirited at the menstrual period, and has had delusions. The urine has contained some albumen, but is now free from it, and of specific gravity 1022. Case 2.—A laundress, aged sixty-five, came under care in 1879, with the signs of myxœdema marked by cardiac disease and ascites, from which she died shortly afterwards. The post-mortem examination showed great swelling of the lower extremities, the skin of the abdomen tense and shining, and the seat of purpuric patches. The superficial vessels of the face were injected. The peritoneal sac contained twelve pints of fluid, and about a pint of effusion occurred in each pleura. The kidneys were cirrhosed; the heart was hypertrophied, mitral and aortic valves thickened. The brain and spinal cord were examined, but showed nothing very distinctive. — Mr. **Hulke** inquired whether, in the second case, any chemical tests had been applied to distinguish the character of the fluid distending the tissues from the dropsical effusion ordinarily present in a subject of long-standing heart disease?—Dr. **Ord** had seen both the cases. The first was a well-marked example of myxœdema, exhibiting general swelling of the integument, which was translucent, dry, and inelastic. There was thinness of the hair—usually met with in these cases; and there was the vivid carmine colouration of the cheeks contrasting strikingly with the extremely pale eyelids. When he saw the case there was no œdematous pitting at any part. She also had the characteristic slowness of speech. The urine contained a slight quantity of albumen, but was not otherwise altered. He asked if Dr. Lloyd could give any information as to the temperature, which is nearly always subnormal. Her gait was characteristic, walking slowly with a tendency to trip, and to give way especially at the knees. The second case was, when he saw it, in the last stage; and after a time these cases lose their characteristic swelling, so that the skin becomes wrinkled and movable; and fresh symptoms, cerebral or renal, supervene and predominate. This patient had manifestly damaged kidneys, cardiac hypertrophy, and much ascites. Dr. Ord was still engaged in examining the tissues of this case, especially the spinal cord, for the nervous symptoms of the disease pointed either to altered relations with the exterior from impairment of the peripheral nerves or to changes in the nerve centres themselves. At first he had thought that the change in the skin was sufficient to account for the impaired activity of the nervous system, and in the first case he had examined no lesions were found either in the brain or cord. In the present case, however, there was general increase in the connective tissue of the cord, especially around the vessels and the central canal; but he had not found any evidence of destruction or degeneration of the nerve elements. — The **President** hoped that Dr. Ord's report would be added to Dr. Lloyd's paper, and at the former's suggestion Dr. Savage was asked to draw up the report in conjunction with Dr. Ord.—Dr. **Andrew Clark** said that for the past ten years he had been more or less familiar with this class of cases, which had been principally brought into notice by Drs. Ord and Duckworth; and with Dr. Burnet's assistance he had been engaged in collecting these cases—in none of which, however, had he obtained a post-mortem examination. His experience of them agreed with Dr. Ord's descriptions, except that he had seen the affection far more often in males than in females. They had a striking resemblance to one another; they speak in the same way, move in the same way, act in the same way. Their well-marked characteristics consisted in the white, dry skin, pink cheeks, broad lips, swollen eyelids, and puffy hands; and they complain of being "bound," as if the muscles of the limbs, and sometimes of the face, were hindered from acting. The urine was of low density, nearly always below 1014. As to nervous symptoms, the majority are noticed to be dull, to have a certain hebetude, and to speak with peculiar deliberation and nasal intonation; the voice in males being low-pitched and rough; in females it reaches falsetto. The last common characteristic is that they nearly all have exhibited nervous symptoms resembling the early stages of ataxy; many are unable to walk in the dark, and many cannot stand with their feet close together. The first impression he had of the nature of these cases was that the disease commenced in the nervous system, then attacked the kidney, producing "renal inadequacy," so that these organs became incapable of excreting a healthy urine, and that subsequently the blood was affected. He proposed shortly to bring these cases before the Society.—Dr. **Ord** said that in four cases in which the urine had been daily analysed, the quantity of urea was found to be much below the average.—The **President** had seen cases, but did not understand their nature until Dr. Ord elucidated it. One case was undoubtedly combined with sclerosis of the nerve-centres, and another, which was under his care fourteen or fifteen years ago, was, he believed, the same as that brought before the Society lately by Dr. Duckworth.—Dr. **Lloyd**, in reply, said the temperature in his case never exceeded 96° or 97°; once it was only 94°.

The business of the annual general meeting was then proceeded with, after which the Society adjourned.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Hyposcleral Cyclotomy.—Rare Form of Muscular Asthenopia.—Ophthalmoplegia Interna.—Detachment of Retina.—Tumour involving Optic Chiasma. — Epithelioma of Orbit.

At the meeting of this Society, held on the 13th inst., W. Bowman, Esq., F.R.S., in the chair, several communications were read, that which gave rise to most discussion being a paper by Mr. Hulke criticising Mr. Hutchinson's hypothesis that cases of total immobility of the pupil combined with loss of accommodation was due to disease of the lenticular ganglia. Mr. Hulke suggested the ganglionic plexuses in the choroid and iris as the probable seat of disease, whereas Dr. Gowers suggested that in these cases there was affection of the centres themselves.

Mr. **Higgens** read a paper on Hyposcleral Cyclotomy, in which reference was made to Mr. J. E. Walker's "Essays on Ophthalmology," where this operation is described and its results in several cases given. The expectation raised by perusal of the essays in question were scarcely realised. Seven cases were reported by Mr. Higgens, and the experience of these cases led him to believe that hyposcleral cyclotomy as a means of reducing ocular tension is inferior to iridectomy.—Mr. **Walker**, replying to the criticisms passed on the operation, stated that in acute glaucoma its superiority over iridectomy was marked, and in chronic glaucoma it often gave a good result. It was founded on the view that the tension in glaucoma was due to changes in the ciliary muscle, and that the habitual strain of this muscle in hypermetropic eyes predisposed them to the disease. This hypothesis seemed to him confirmed when he noticed that in certain cases of astigmatism the ciliary muscle appeared to act unequally, an occurrence which seemed to harmonise with Dr. Brailey's observations on partial sclerosis and atrophy of the ciliary muscle in glaucomatous eyes. The success of iridectomy or sclerotomy in glaucoma depended on the escape of fluid through a scleral fistula; but by division of the ciliary muscle only in cyclotomy the tension was remedied without this taking place. He hoped that Mr. Higgens would not abandon the operation, but give it a fair trial. At the request of Mr. Spencer Watson, he briefly described the method of operating.

Dr. **Brailey** read a paper "On a Rare Form of Muscular Asthenopia," describing a case in which with normal power of both internal and external recti, and with very abundant accommodative power, though unaccompanied by spasm, there was great irritation, with pain, on any use of the eyes. The patient, a very intelligent gentleman, aged thirty, had a low degree of myopia, with a little myopic astigmatism. When, however, these were fully corrected, the symptoms of asthenopia were even more pronounced than before; nor did correction of the astigmatism by cylinders alone give any material benefit, though when these were for near work, combined with weak convex sphericals, he obtained some temporary relief. But a permanent and far greater beneficial effect was produced when a prism, apex downwards, before the left eye was added to the cylinders. He has worn this combination during several hours daily for many months, and its beneficial effect still continues. With its discontinuance the symptoms return.—In reply to Mr. Nettleship, Dr. Brailey said that since using the glasses the patient had worked more than before. In fact, he had been almost compelled to abandon his pursuits prior to treatment; and in reply to the President he said that the affection was of many years' standing.—Mr. **COUPER** said that he had found it useful in muscular asthenopia to employ prisms for a certain time each day to force the weaker muscles into play, instead of in the opposite direction, for the purpose of relieving the affected muscles. In cases of weakness of the internal rectus he had found great benefit from thus using gradually stronger and stronger prisms.

Mr. **HULKE** read a paper "On Ophthalmoplegia Interna" (paralysis of the ciliary muscle, and of both the circular and radiating fibres of the iris), which he stated is not pathognomic of disease of the lenticular ganglion, but is with great probability referable to disease of the ganglionic plexuses within the eyeball in immediate relation with the intraocular muscular apparatus. The hypothesis that these symptoms are caused by disease of the lenticular ganglion rests on the assumption that the iris and ciliary body receive all their nerves through the lenticular ganglion. This assumption can no longer be maintained, since (1) it has been experimentally proved in dogs and rabbits that after removal of this ganglion the radiating (dilating) muscular fibres of the iris still contract if the sympathetic in the neck be stimulated, and (2) pupillary dilating nerve-fibres have been proved to accompany the first division of the fifth nerve, and to reach the eyeball without traversing the lenticular ganglia. Ganglion cells were shown to be present in the choroid and ciliary body many years ago by Schweigger and the author, and their presence has since been verified. It is suggested that they may be immediately concerned in the movements of accommodation and pupil.—Mr. **HUTCHINSON** was indebted to Mr. Hulke for the criticism of his paper, written two years ago, recording four or five cases of a very rare condition, in which the iris remained incapable of dilatation or contraction, combined with paralysis of accommodation, but no paralysis of the external muscles of the eye. But he was disappointed at the scope of Mr. Hulke's paper, which dealt only with certain familiar points in anatomy and physiology, for he hoped that Mr. Hulke would have produced facts upon the affection from his great fund of clinical experience. He held, however, in the main to the belief stated in his paper, which he had carefully considered before publishing; and he had not overlooked the fact that the parts involved received other sources of sympathetic supply than by way of the lenticular ganglia. He would have been glad if Mr. Hulke could have shown that the ganglionic plexuses were the seat of disease, for such a fact would have lent great support to a point of speculative pathology upon which he had dwelt in his lectures at the College of Surgeons—viz., that "trophic" changes were due to the association of vaso-motor fibres with sensory nerves, and not to any special trophic influence in certain sensory nerve fibres. Although the view sketched by Mr. Hulke was probable, yet was it not less probable than that which he had suggested—viz., that the conditions were due to disease of the lenticular ganglion. The fact that experiments showed that the pupil would dilate under atropine, or stimulation of the cervical sympathetic after extirpation of this ganglion, did not disprove his hypothesis. It is quite likely that galvanism of the sympathetic, could it have been practised, would have influenced the pupil in the cases he had described. What would be the symptoms of disease of the lenticular ganglion if not such as these? Neither hypothesis had been proved; but it was at least improbable that the disease should involve so large an extent of surface as must be the case if Mr. Hulke's theory be correct; and it would be more likely that it should involve so compact a body as the lenticular ganglion. That atropin and eserin act on the pupil after removal of this ganglion was rather in favour of his own view, for they so acted in his cases; and it might be doubted if they would cause any effect were the peripheral nerves involved. He did not mean by ophthalmoplegia interna that the pupil does not respond to any influence. The subject was one of great interest, and possibly there might be other causes at work—e.g., disease of the nerve-centre; for one of his cases was associated with locomotor ataxy. But he maintained that his own interpretation was more consistent with the facts of the affection than Mr. Hulke's.—Dr. **GOWERS** interpreted Mr. Hulke's theory to be that degeneration of the ganglionic cells destroyed the mechanism by which reflex action works. Each theory supplied an adequate explanation of the phenomena. Stimulation of the sympathetic might possibly afford some means of distinguishing the true seat of disease; for in that case no effect should follow were the ganglionic cells diseased (as the sympathetic fibres do not pass through the lenticular ganglion). But if the ganglion were diseased slow dilatation of the iris should persist in stimulation of the sympathetic. And in man such excitation of the sympathetic could be effected by simply stimulating the sensory fibres. But both these theories failed in having any direct or indirect proof. The evidence was much greater in favour of central disease. In the floor of the third ventricle there were a series of nuclei close together, influencing respectively accommodation, the pupil, and the muscles of the eyeball; and they were so far distinct as to be capable of separate stimulation, and from disease of each might arise (1) ophthalmoplegia externa, (2) loss of reflex action of pupil to light, (3) loss of accommodation. Loss of reflex action of the pupil to light is very frequent in locomotor ataxy; and also in syphilitic subjects without ataxy, which had been mentioned by Erb, and Dr. Gowers had seen three cases. Ophthalmoplegia externa occurs occasionally in constitutional syphilis. Ophthalmoplegia interna was met with by Mr. Hutchinson, associated with ataxy in one case, and with syphilis in all his cases. There could hardly be loss of reflex action of the pupil, except from central disease. He thought it then very probable that ophthalmoplegia interna was due to disease in the situation of the nuclei. The selection of so limited an area by a lesion was not more surprising than occurred in other diseases of the nervous system—e.g., locomotor ataxy, or labio-glosso-pharyngeal paralysis.—Mr. **HULKE**, in reply, said that so far as he could judge of the matter, he still held that if—in the absence of the lenticular ganglion—the movements of the pupil still remained unaffected, and the mechanism of accommodation uninjured, there was no proof that the condition in which these actions were destroyed was due to disease of that ganglion.

Dr. **DAVIDSON** exhibited a specimen and drawings of Detachment of the Retina in a case of Bright's disease. The patient was admitted into hospital with right hemiplegia and aphasia a day after an apoplectic seizure. The urine contained albumen, and there was a systolic bruit at the heart's apex. There was complete paralysis of the right external rectus, and severe neuro-retinitis, with hæmorrhages. Blindness gradually supervened, and detachment of the retina was discovered. Death took place about seven weeks after admission, and, in addition to cerebral hæmorrhage, the kidneys were found to be granular, the right extensively atrophied, and the left ventricle of the heart hypertrophied.

Dr. **FITZGERALD** (of Dublin) communicated a case and drawing also of Retinal Detachment in Bright's disease. The patient was a female, admitted with much dropsy, under the care of Dr. F. B. Quinlan, and renal albuminuria. There was considerable impairment of sight of the left eye, where, in addition to albuminuric retinitis, there was an extensive detachment of the retina. She died from uræmia nine days after admission, and the kidneys were found to be of the large white form.

Mr. **McHARDY** exhibited a specimen of a Tumour involving the Optic Chiasma, from a woman thirty-five years old, who had been ill for seven months and had complained of failing vision for three months. At the same time she suffered from pain in the head, and especially in the occipital region, with deafness and a gait suggestive of cerebellar disease. There was also great thirst. Vision was much impaired, and examination showed appearances of white atrophy of both discs, but no evidence of neuritis. After death the optic commissure was found to be involved in an irregular tumour lodged between the crura cerebri, extending in front to the longitudinal fissure and involving the root of the right olfactory nerve and the right optic tract and nerve.

Dr. **GOWERS** had seen a case of tumour in this situation which was associated with optic neuritis. He had also observed a case where pressure at the back of the orbit had produced an atrophy of the optic nerve resembling that of locomotor ataxy.

Dr. **LEDIARD** (Carlisle) communicated notes of a case of Epithelioma of Orbit in a man seventy-four years of age, who had previously suffered from epithelioma of the lip. The orbital growth was of four years' duration, had destroyed the lower eyelid and partially involved the eyeball. The diseased structure was removed.

HARVEIAN SOCIETY OF LONDON.

THE annual meeting of this Society was held at the Stafford Rooms, Edgware-road, on Thursday evening, Jan. 6th, 1881, for the election of officers and the President's address.

It is usual, in addition to the ordinary routine business, to hold a conversazione on the occasion of the annual meeting, but the council recommended that this year the soirée should be on a larger scale, and be held at the South Kensington Museum in the summer, in consequence of the Society having reached the age of fifty years. Mr. Henry Power, the president, delivered a most interesting address. He commenced by thanking the members for the honour, unprecedented in the history of the Society, that they had conferred upon him in electing him for the second time to fill the office of President. He referred to the ready assistance he had at all times received from the secretaries, Mr. Field and Dr. Fothergill, and attributed the great increase in the numbers of the Society and the corresponding improvement in the finances to their unflagging activity and zeal. He then gave a short account of the several papers that had been contributed in the course of the past session, including those from Dr. Broadbent, Dr. Ferrier, Mr. Knowsley Thornton, Dr. Meadows, Mr. Teevan, Mr. Field, and many others. Mr. Power then proceeded to point out the circumstances which were gradually effecting improvement in the general status of the profession, and the estimation in which it was held by the community at large. He thought that this was due to several causes—first, to the younger members of the profession being more uniformly drawn than formerly from the middle or better classes; secondly, to the circumstance that the education afforded to them was very superior to that given to the last generation, the time being more prolonged, whilst the subjects were taught in a more practical manner; lastly, the methods adopted in physiological research were evidently being adopted in the practice of medicine, rendering it far more precise and accurate in the present than in the past.

The following is a list of the names of gentlemen elected as officers of the Society for the year 1881:—President: Mr. Henry Power. Vice-Presidents: Mr. F. J. Gant, Dr. W. H. Day, Dr. Milner Fothergill, and Mr. H. Sewill. Treasurer: James E. Pollock. Hon. Secretaries: Mr. George P. Field and Mr. Malcolm Morris. Council: Drs. G. C. P. Murray, W. Squire, G. Danford Thomas, J. W. Langmore, T. T. Whipham, J. F. Payne, F. A. Mahomed, and Messrs. Alfred Cooper, Osman Vincent, Robert Argles, W. Towers Smith, and W. Rayner.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

AT the third meeting of this Society, held on the 3rd ult., Dr. Hitchcock (President) in the chair, Mr. S. OSBORN, F.R.C.S.E., read a paper on Phimosis as a cause of Hernia in Infants. Having, in his capacity as Surgeon to the Surgical Appliance Society, to examine and apply some hundreds of trusses in the course of the year, the frequency of phimosis in combination with rupture in infants had struck the author repeatedly. The phimosis in all these cases he was certain was the undoubted cause of the rupture, and might be thus explained: After the descent of the testicle into the scrotum has been accomplished the vaginal process of peritoneum, through which it descended, begins to close and become converted into a fibro-cellular cord. But the testicles having but lately descended (the left coming down between the seventh and eighth month of fœtal life and the right between the eighth and ninth month), the uniting medium is but yet young, and not being sufficiently organised is easily broken down by any strain thrown upon it. Phimosis occasions that strain from the impediment which it offers to the outflow of urine. For the mechanism of ordinary micturition is effected by the contraction of the muscular coats of the bladder and urethra, but in cases of obstruction to the outflow of the urine extraordinary force is called into action, and this is effected by the contraction of the abdominal walls pressing upon the bladder, whilst the diaphragm is also at the same time in a state of tension. By this means pressure is exerted over the whole of the abdominal wall, and the apertures by which the testicles have descended to the scrotum being always the weakest points of the abdominal surface, they naturally give way under the strain thrown upon them. In other words, the child, straining to pass his water, forces the abdominal contents downwards upon the weak points at the inguinal canals, and rupture on one or both sides results. It might even be said that the canal which has been the last to close, or, in other words, that side on which the testicle was the last to descend, is the side on which the rupture usually occurs; and, knowing that the right testicle is generally the last to descend, we naturally find that hernia in infants is also met with with greater frequency on this side. That the rupture occurs on the side on which the testicle was the last to descend is only what might be expected, for the uniting medium which is effecting a closure of the canal on this side is not in so advanced a condition of organisation as on the other side, where the testicle has taken its place prior to the other. It is thus easily seen how a single truss frequently produces a double rupture. The cause of the obstruction to the outflow of urine is still present in the phimosis, and one inguinal canal being guarded by the single truss, the abdomen gives way at its next weakest point—viz., the other inguinal canal, and a double rupture is the consequence. Such a result might have been prevented by early circumcision. The hernia in these cases is generally scrotal, or, if not, it soon becomes so by the wedge-like projection of the intestine; and as to whether it be congenital or infantile in variety depends upon the amount of the funicular process of peritoneum which becomes converted into fibro-cellular tissue, or which has been broken down by the aforesaid propulsion of intestine. The operation of circumcision, as performed upon young children, and which was done in all of the cases the author had spoken of, is both easy of performance and effective in its results. No sutures are ever required, children bear the pain well, and the parts are usually well in a week or ten days. The hernia then stands every chance of being effectually cured by the application of a truss, the exciting cause having been removed; at all events a double rupture is prevented by its early adoption. He would suggest that whenever an elongated or contracted prepuce is present in infants, the sooner circumcision is performed the better; thereby the more serious complaint of rupture will be prevented.

Reviews and Notices of Books.

The Quarterly Journal of Microscopical Science. No. LXXXI. Jan. 1881. London: J. & A. Churchill.

THIS part contains the following memoirs:—1. Notes on a Peculiar Form of Polyzoa, closely allied to Bugula, by George Busk. 2. On the Germination and Histology of the Seedling of Welwilischia mirabilis, by F. Orpen Bower. 3. Notes on some Reticularian Rhizopoda of the *Challenger* Expedition, by Henry B. Brady. 4. On the Head Cavities and associated Nerves of Elasmobranchs, by Milnes Marshall. 5. Contributions to the Minute Anatomy of the Nasal Mucous Membrane, by E. Klein. 6. Histological Notes, by E. Klein. 7. On the Intra-cellular Digestion and Endoderm of Quinocodium, by E. Ray Lankester. 8. On the Micrometric Numeration of the Blood-Corpuscles and the Estimation of their Hæmoglobin, by Mrs. Ernest Hart. 9. Preliminary Account of the Development of the Lampreys, by W. B. Scott. 10. On Some Appearances of the Red Blood-Corpuscles of Man and other Vertebrata.

The chief paper of interest to professional readers is that of Dr. Klein on the Minute Anatomy of the Nasal Mucous Membrane, in which he particularly describes the organ of Jacobson. The structure known under this name is found in a rudimentary state in man at the lower part of the nasal septum; but it is highly developed in the guinea-pig, in which animal Dr. Klein has chiefly examined it. It is a tubular structure, flattened from side to side, and leading in front into the ductus Stenonianus, which opens into the oral cavity. It terminates behind cæcally. It is surrounded not by the bone of the septum, but by hyaline cartilage, which forms a more or less complete capsule for it, separate from the cartilage of the septum and below the septum. The lateral wall of the organ of Jacobson consists of the epithelium lining the cavity, a subepithelial fibrous layer, a layer of cavernous tissue, and a layer of glands. The epithelium resembles that of the nasal mucous membrane, generally consisting of ciliated columnar cells, with some goblet cells. The glands consist of more or less branched and convoluted tubes. The *median* wall is covered with a thick sensory epithelium, and presents many fine nerve fibres, chiefly derived from the olfactory nerve, but in part also from the naso-palatine nerve. Dr. Klein describes these cells very minutely.

Surgical Lectures delivered in the Theatre of the Westminster Hospital. By RICHARD DAVY, M.B., F.R.C.S., Surgeon to the Hospital. London: Smith, Elder, & Co. 1880.

MANY of the lectures collected in this volume have been already published in full or in abstract in one or other of the medical journals. They each and all bear the impress of originality, especially perhaps in the manner in which the subjects are treated, which is slight, dogmatic, and frequently humorous and quaint, though some may think it hardly advisable to have crystallised in this manner all the pleasantries of the lecture-room. The lectures to which most interest attaches are those on the treatment of talipes by excision of the tarsal arch, and on the compression of the common iliac vessels by a lever passed per rectum. The latter method is an established practice now in amputation of the hip-joint, and is certainly a valuable surgical acquisition, for which we are solely indebted to Mr. Davy. His method of applying Sayre's plaster-of-Paris jackets to patients suspended in hammocks has many advantages over the extension plan of Dr. Sayre, and is hardly so widely known as it deserves. Mr. Davy gives a table of twenty cases of excision of the knee-joint, all of them followed by recovery, but only two of these patients were adults, the other eighteen ranging from two to fifteen years of age. This operation is not generally performed so frequently at such an early age, and it would be exceedingly interesting to know the ultimate result of the operation in these cases, whether the limbs are so shortened as to be but of little service. In two of the cases of complete excision, only fibrous anchylosis was obtained, and in one of the cases amputation of the limb was afterwards performed. Mr. Davy makes a contribution to the discussion of the best means of treating wounds, which he considers to be to leave them without any dressing at all.

Lectures on the Surgical Disorders of the Urinary Organs. Delivered at the Liverpool Royal Infirmary. By REGINALD HARRISON, F.R.C.S., Surgeon to the Infirmary, &c. Second Edition, considerably enlarged. London: J. & A. Churchill. 1880.

THIS edition is double the size of the former one, twelve new lectures being added, and the old lectures variously improved. The subject of Stone in the Bladder in particular is more fully dealt with both from its theoretical and practical points of view. Mr. Harrison supports Drs. Carter and Ord in their view of the influence of colloids in the formation of calculi, and he advances the suggestion that irritation of the urinary organs, causing an increased secretion of colloidal mucus, leads to concretion of the solid constituents of the urine. While we may admit that there is some evidence in favour of this view, we cannot lose sight of the important influence of the composition of the urine in the deposit of calculous material.

The present edition is considerably increased in value by the new matter added; and even if we cannot agree with all the views expressed, it is impossible to read these Lectures without profit and interest.

Transactions of the Pathological Society of London. Vol. XXXI. London. 1880.

AS we furnish so full a report of the meetings of the Pathological Society, it is hardly necessary to do more than mention the publication of the annual volume of the Transactions. Like its predecessors, it is full of careful descriptions of interesting pathological conditions, and, although it does not contain any "discussion," or "report" similar to that of the Pyæmia Committee last year, it is worthy to rank with any of its predecessors. There are a large number of well-executed engravings, and a few coloured plates, the Council having spared no pains or expense in the preparation of the volume. The descriptions of the specimens exhibited "by card" are printed in small type.

ABSCESS OF THE BRAIN IN A FŒTUS.

To the Editor of THE LANCET.

SIR,—The following case seems to me a rare one. I was called in to attend a multipara, who had engaged a midwife. The latter, finding something wrong, sent for me. The patient had been suffering much pain for several days, but true labour pains had only been present for five or six hours. She had not felt the child for ten days, and was convinced that it was dead. On digital examination a finger-like pouch was found projecting into the vagina. The finger being carefully passed up to the neck of the womb, it was found to be dilated to the diameter of about two inches. The finger encountered a detached bone, evidently one of the parietal bones, and could be passed on both sides of the bone. During the progress of the labour the pouch became larger, and when the membranes broke it was found to consist of the loose scalp filled with some fluid. When the child was born it had apparently been dead for the period supposed by the mother. The skull was collapsed, and contained about a third of its usual contents; the bones were all loose, and several completely detached from their articulations, and entirely denuded of pericranium and dura mater. I had no knife with me at the time, and was only able to make a very incomplete examination next day, but I made then an incision through the scalp, when a quantity of pus discoloured with dark blood gushed out; pus of the same kind was found to have filled the mouth and nostrils; but little brain tissue could be detected, and that appeared to consist entirely of the convolutions; the whole of the base of the brain was broken up. On passing a finger into the skull the bones of the base were felt bare and loose, and with one finger in the mouth and another in the skull the palate and sphenoid bones could be lifted up and moved about quite freely. The rough edges of the sphenoid could be felt distinctly.

The patient attributed the death of the child to two frights she had received during pregnancy; the first when she had just quickened, and the second six weeks before the birth. Could the first have caused hydrocephalus, and the second have set up acute inflammation, ending in suppuration? I forgot to state that the placenta was small, and had numerous hard fibroid masses in it. There was an offensive discharge from the uterus for a few days after the labour, and carbolised injections were freely used; but there were no bad symptoms, and the temperature never rose above 101° F. Perfect and rapid recovery took place. There was no trouble with the breasts.

I am, Sir, yours, &c.,
R. H. BAKEWELL, M.D., &c.
Hokitika, New Zealand, Nov. 1st, 1880.

THE BRITISH MEDICAL BENEVOLENT FUND.—At the annual meeting of the above Fund, held on the 18th inst., the following resolution was carried :—"That the best thanks of this meeting be given to the Editor of THE LANCET for the kind services rendered by him to the Fund."

THE LANCET.

LONDON: SATURDAY, JANUARY 22, 1881.

WE have recently on two or three occasions foreshadowed a new and hopeful departure in the movement for Medical Reform, the principal aims or provisions of which we may now more particularly indicate. It is reasonable that, with a new Parliament, this question should be put into its best form, and presented under conditions calculated to make the strongest impression on the Government and the Legislature. This is what we mean by a new departure. Let us briefly sketch the more prominent features of this fresh demand for medical reform.

In the first place, it is to have for a basis the general judgment of the profession. It is not to be the work of one association or of another, but of the profession itself. Associations, however large, are not the profession. There is a feeling that they can be manipulated by cliques and committees and wire-pullers. We share that feeling, and we participate in this movement only on the understanding that the profession is to take the leading part, and that the demands made are to be based on the judgment of the profession, so far as that can be ascertained. To accentuate this essential feature of the new effort an appeal to the profession will be made, in the name of a Conference in which various associations were represented, but in which none were predominant, and the chairman of which (Dr. ANDREW CLARK) has shown himself to be most deeply and disinterestedly in sympathy with the profession. It is refreshing to find a physician of the highest standing who believes the profession to be greater than its corporations, and who does not think so meanly of it as to be afraid of giving its experienced and hard-working practitioners representation in the Medical Council. So much for the basis and the new executive of this movement.

We now come to the essential features of the reform embodied in the Bill of the Conference, which it must be clearly understood is to be a measure framed by the Conference, and not by any one of the bodies represented in the Conference. The chief provisions may be briefly stated thus:—

1. It is to provide for the establishment of a Conjoint Board in each division of the kingdom.
2. It is to reduce the number of corporations in the General Medical Council by three.
3. It will give direct representation to general practitioners in each division of the kingdom.
4. It will make the General Medical Council a responsible body, with authority over curricula, examinations, &c.
5. It will require equality in curricula, examinations, and fees for examination in each division of the kingdom.
6. It will recognise the claim of universities to have their graduates or candidates for their degrees exempted from all but the clinical or practical part of the examinations of the Conjoint Board.
7. It will strengthen and amend the clauses which punish fraud on the public by false pretences to being qualified to practise medicine.

Any Bill that fails to ensure these points of reform must be an imperfect measure, and our interest in it will abate or cease with any serious unfaithfulness to these principles. The establishment of Conjoint Boards is, of course, simply an indispensable step. The "nineteen competing bodies" must cease to compete, and, barring the three which it is proposed to relieve from further public duties, must co-operate in the formation of a Conjoint Board in their respective divisions of the kingdom.

Everybody feels that there are too many Corporations, and that their influence in the Council is hindering and injurious. The difficulty has been to know how best to diminish it. Mr. SIMON'S proposal is to consolidate the representation of the corporations. "If," he said in his evidence before the Select Committee, "the authorities were consolidated for licensing and examining purposes, I do not see why they should not be consolidated for Council purposes, and why the Council should not be reduced to one-half its size." This is almost precisely the proposal of THE LANCET Bill in 1870, which gave a Council of twelve, four elected by the Crown, four by registered practitioners, and four by the consolidated and co-operating authorities—two for England, and one respectively for Scotland and Ireland. And there is still much to be said for this kind of Council. Meantime we must be content with relieving a corporation in each division of the kingdom of its public duties—namely, the Apothecaries' Society in England and in Ireland, and the Faculty of Physicians and Surgeons in Glasgow. If any worthy licentiate of these bodies thinks he is going to lose anything by this reform, let him be undeceived. He has no more part or lot in the representation of these bodies than he has in the thriving drug trade carried on by the two former societies. The representative of the Council of the London Society in the General Medical Council is appointed by 24 persons, called mysteriously the master, the wardens, and the assistants. The representative of the Apothecaries' Hall of Ireland is elected by 31 persons, called the General Court or Council. The representative of the Faculty of Glasgow is elected by 170 persons, known as Fellows of the Faculty, differing from their humbler associates, the licentiates, not in having passed any higher examinations, but in having paid two additional sets of fees—the main care of Corporations. It is high time that room was made for the direct representatives of general practitioners by the abolition of the representation of 24, 31, and 170 persons respectively. The modest disfranchisement of the Conference Bill leaves two Royal Colleges in each division of the kingdom, while it gives a vote to every registered practitioner for representatives that will view questions in the broad light of the profession, instead of the narrow light of small and almost commercial corporations. Another serious reason for relieving these superfluous corporations of the duties of medical authorities is to keep down the conjoint fees. These bodies are not needed. As Sir JAMES PAGET said, no one with the diploma of two Royal Colleges will care to ask for the diploma of the Faculty of Physicians and Surgeons. Still less will he care to have the licence of either of the Apothecaries' Companies. In the name of all that is reasonable, then, let us not entail on future generations of medical men a tax for their superfluous and injurious maintenance.

We must defer the further notice of the Conference Bill. Meantime we urge on every practitioner to give prompt and immediate consideration to its proposals.

◆

THE highest form of statesmanship does not wait until questions of public interest have so "matured" as to be mischievous, before it begins to legislate. Government, by or in consequence of agitation, has many drawbacks, not the least of which are the disturbance and final withdrawal of confidence which have to be produced before a Ministry will move. This is a consideration which may be worthy the attention of our rulers in regard to not a few of the questions of reform which have been persistently pressed upon their notice session after session during a long series of years! It is not the fault or weakness of one party in the State more than of another to plead that questions are not "matured" until agitation has done its utmost to compel legislation, and at the same time wrought mischief by disturbing and destroying public confidence in the system it is deemed necessary to reform; but it is a very serious fault, and one from which the community at large severely suffers. The particular manifestation of this evil to which we are at the moment desirous of directing attention is the provoking delay of Lunacy Law Reform, until not only is agitation drifting into bad courses, but, as a fruit of the shaking of confidence it has produced, the public is resorting to a policy of concealment at once disastrous in itself and fraught with new and personal dangers. Let us at once say that we have nothing to urge against the *treatment* of lunacy or mental disorder in private houses; the evil to which we point is concealment—a concealment forced on the friends of the insane by the fears excited by agitation, and which the Legislature will not allay.

The proportion per cent. of lunatics in private asylums and of persons known to the Commissioners as insane is decreasing. What does this mean? With that shortsightedness common to public officials, the Commissioners in Lunacy and their friends and supporters interpret the figures as indicative of a decrease, or, at least, a diminished rate of increase, in the number of occurring cases of insanity. They are oblivious to the fact that the long vexing of this question of reform, and the opposition offered to a satisfactory settlement of the issue raised in the mind of the public, have had the effect of destroying confidence in the asylum-system and the protective power of the Commission; and that, in consequence of this altered feeling, the friends of the insane do not—unless driven to take the justly dreaded step—bring their patients under the official cognisance of the Commissioners. Never before, perhaps, was the practice so general as at this moment of keeping persons of unsound mind in the houses of members of their own families under the care of "trained nurses" and attendants. The Commissioners know absolutely nothing of these cases. The law, as it stands, gives them no jurisdiction in the matter. It is only when some person makes profit by taking charge of a lunatic the poor sufferer from mental disease comes under the *protection*—such as it is—which the Commissioners are able to afford. In this case, as in many others, there is practically one law for the rich and another for the poor, but in the present instance the rich fare the worst. Patients among the fairly well-to-do classes are kept at home in carefully padded rooms under mechanical—or irritable muscular—restraints, or are farmed out under the care of persons who have no special fitness for, or the experience which sometimes does duty for fitness, in the management of the insane. In this latter case, as some one *does* "make a profit" by them, the lunatics ought to be known to the Commissioners, but as a matter of fact they are not. Patients of this class are described as "nervous," "weak-minded"—anything except "insane or of unsound mind,"—and practitioners in mental disease can scarcely be blamed for lending their sanction to the secrecy.

All this, and it cannot be disguised that it constitutes a most perilous state of affairs, is the direct and inevitable fruit of agitation without legislation. The public have lost confidence in the management of private asylums, and while the Government is too busy to attend to the real needs and grievances of the community, the friends of the insane resort to the only expedient open to them—namely, keeping them under their own personal observation. It is not improbable that the larger part, if not the whole, of the seeming decrease of the total of "private patients" upon which the Commissioners in Lunacy are disposed to congratulate themselves and the public, may be accounted for by the measure to which the growing distrust of the public is driving the relatives of the mentally diseased. This is a gigantic evil, and we must hold successive Governments responsible for the consequences which are beginning to ensue. There is something so ludicrous in the state of the law which allows private patients treated in their own families to remain unregistered, while it makes the process of registration by "certificates" a terror to every sound mind, that if it were not a very grave matter the predicament in which the Commissioners are involved might be regarded as making them and their official work a laughing-stock. It is, however, impossible to look at the matter in this irreverent light. The gravest consequences are certain to be entailed on the community if legislation is not hastened, even at the cost of distracting the minds of our representatives in Parliament for a moment, from the more "interesting" questions of Irish "Boycotting" and land-law reform.

We are not alarmists, and we have certainly no wish to hamper the hands of the Ministry at this conjuncture, but it is a public duty to speak out; and—in the presence of certain serio-comic efforts of the Commissioners in Lunacy to search out and prosecute a few isolated cases of secret "farming," and, in consequence of facts known to ourselves—to show that the practice of evading the miserable law which exists is becoming widespread, and the perfunctory and sensational discharge of duty by the legal guardians and protectors of the insane is degenerating into a farce—a more conspicuous farce than the proceeding of registering a long catalogue of names, and professedly watching over the persons who bear these names, without having the means or power of even identifying them! The time has come to deal plainly with the subject of Lunacy Law Reform, and if there is, as would seem to be the fact, a settled determination in official circles to play with the question, then we must press it upon their consideration more forcibly, and with greater earnestness than we have hitherto deemed necessary. It cannot be endured that official apathy, and the misconstruction placed on official figures by incompetent statisticians, should bring down on the community evils which it will hereafter cost a world of trouble and expenditure to cure. If once the practice of *concealing* lunatics in private families is allowed to become general, as we affirm it *is* becoming general, it will be impossible to eradicate the evil by any tardy change in the law. Our own strong leaning is, as we have said, towards a policy of placing mental disease on the footing of ordinary disease, and leaving it to be treated by the medical profession on general principles, and, in the case of private patients, in private houses, without — except in cases of special necessity — their being taken out of the protection of their own families. We think the best results would be gained by this method of dealing with the question, the legal process of imposing social disabilities upon lunatics being left to the lawyers, as a matter totally apart, and entirely distinct and different in its nature. Meanwhile, all are agreed that the *hiding* of lunatics in upper and back rooms where they are subjected to nameless cruelties under the guise of kindnesses is a wrong of the greatest magnitude; and it is this hiding and this secrecy which the reckless or perverse delay of reform encourages, and which the Commissioners in Lunacy mistake for a "decrease" of lunacy in the class of private patients. It is time that public opinion should be moved to protest.

◆

M. Richet, in a lecture delivered as one of a course auxiliary to that of the Faculty of Medicine of Paris, has just given a very full and complete *résumé* of the present state of our knowledge of Rigor Mortis, which has engaged the attention of observers from the time of Louis, who in 1752 wrote an essay upon it, in which he pointed out that it was one of the principal signs of death. Nysten, in the early part of the present century, demonstrated that cadaveric rigidity is due to the condition of the muscles, since if the ligaments of the joints, the fasciæ, and the aponeuroses, are all divided, rigor mortis persists, whilst it is removed or prevented by division of the muscles or by the separation of them from their attachments. Brown-Séquard and Kühne next examined the phenomena in question minutely, the former showing that it could be removed by the injection of blood into the vessels, and the latter demonstrating that it was essentially a chemical action. It may be stated generally that rigor mortis is never absent; the few cases in which reliable authorities have believed that it has not occurred having probably been instances where it has occurred extraordinarily early or late. It occurs in all animals, both vertebrated and invertebrated. In fishes it takes place almost instantly after death, whilst in frogs, if due precautions be taken, it does not occur until after the lapse of eight or ten days. It has no relation, therefore, to the temperature of the blood of the animal. The first muscles to undergo rigor mortis appear to be those raising the lower jaw, as the masseter, temporal, and pterygoid, which are very irritable muscles. M. Niderkorn finds that in 113 subjects rigor mortis was complete at the fourth hour in 31, at the sixth hour in 20, at the fifth in 14, at the third in 14, at the seventh in 11, at the eighth in 7, at the tenth in 7, at the ninth in 4, at the thirteenth in 2, at the second in 2, and at the eleventh in 1. It commences about two hours after death, and in the human subject is usually complete about the fourth hour. It may supervene whilst the animal is still warm, as is seen in those which have been hunted to death. On the other hand, its appearance is retarded by cold, whilst its duration is almost indefinitely retarded by it. A muscle which has become rigid after death becomes still more rigid if exposed to a temperature of 120° F. This increase, according to Kühne, is due to the coagulation of the serine and caseine contained in the muscular juice. Mere congelation of a muscle does not cause it to lose its irritability, but it very rapidly becomes rigid when thawed.

The remarkable positions sometimes assumed by men killed on the field of battle have been described by many observers, and demonstrate that rigidity may supervene at the moment of death. Brown-Séquard has, indeed, recorded a case of adynamic typhoid fever, in which the jaws and limbs became fixed, whilst the heart still continued to beat; and quite lately the same thing has been recorded by M. Bochefontaine in dogs poisoned with salicylate of soda, and M. Richet has observed it in animals poisoned with medium doses of strychnia. In these cases all the muscles were rigid and unexcitable, with the exception of the heart; and artificial respiration could only be maintained with difficulty owing to the rigidity of the chest. Division of the nerves supplying a muscle appears to have little or no effect in accelerating the occurrence of rigor mortis, and, according to Hermann, neither exposure to oxygen nor to the vacuum of an air-pump exerts any influence.

In becoming rigid, muscles slightly diminish in volume; they shorten less, at least with moderately heavy weights, than muscles in contraction; they entirely lose their irritability, and their elasticity is greatly impaired. Heat is eliminated whilst rigor is being established.

In regard to the cause of rigor mortis, which is an extremely interesting point, M. Richet is of opinion that, as Kühne originally maintained, it is a chemical process; but this process is a phenomenon not of life but of death. The myosine of the muscle coagulates. The acids, which are constantly being formed and as continuously removed during life, accumulate after death in the muscle, and gradually effect the solution of the myosine, and then the azotised matters undergo decomposition and develop ammonia, which, in its turn, dissolves the myosine, and thus occasions the disappearance of the rigor. Speaking generally, rigor mortis is a chemical phenomenon, characterised by the coagulation of the myosine, and may be considered as the commencement of the death of the elements of the muscle.

◆

The recent correspondence in *The Times* on the restraint of scarlet fever furnishes another and most striking illustration of the injudiciousness, and even mischievousness, of medical men discussing in the general press questions of a strictly technical nature. In this case it may be said that the subject under consideration is of great interest to the public at large, even greater than to the profession. In other words, that it is both a public and a professional subject, and that it is indifferent whether it be made matter for general or for professional discussion. But so far as the general public is concerned, this presupposes that the strictly technical questions from which the public considerations have to start have been fairly settled by those who are presumed to possess special opportunities of, and the particular training for, judging them, and that there is some reasonable accord among these skilled individuals as to the judgment formed. Let us see how this stands in the correspondence referred to, and ask in what light it must present the medical profession in perhaps the most familiar disease it has to deal with in this country.

First, Dr. Wynter Blyth writes to *The Times* stating that it is "possible, by a very simple process, to render scarlatina convalescents absolutely harmless." In support of this he sets forth a theory of the duration of the infectiveness of scarlet fever peculiar to himself, and, as yet, unconfirmed and untested by other medical observers, and then proceeds to show that, notwithstanding the prettiness of the theory, scarlet fever may continue to be infective as long as other medical observers have found it to be. Further, he proceeds to illustrate his position by so-called "experimental" proof; and then he proceeds to qualify his recommendation by adding that, "providing the process in its minutest details is carried out thoroughly, a patient may mix with impunity with healthy people as early as the eighth day, if free from fever"; and, again, "it is only in those cases in which the process recommended has been followed out thoroughly, under skilled supervision, that I would dare to recommend the exposure of a convalescent at so early a period. In any other case such a procedure would be fraught with great public danger." Setting aside the technical questions which are here raised, it must be obvious that this qualification neutralises the public-health aspect of the case, and reduces the application of Dr. Blyth's proposed extension of the late Dr. Wm. Budd's plan of "laying" the contagious dust scattered from the skin of a person sick with or convalescent from scarlet fever, by anointing with oil or glycerine or other unctuous material, pretty much to the practice of it now in vogue. Dr. Blyth's proposition of establishing "disinfecting halls" for convalescents from scarlet fever does not much mend the matter as a practicable public-health suggestion.

A proposition of this sort addressed to the general public seemed to us at the time of its being made to be so obviously contradictory in the terms in which it was made that the technical elements scarcely called for remark, and the public might have been credited with sufficient judgment to determine for themselves how it would affect them. But this was not to be. Dr. Alfred Carpenter comes to the front to say that "he had never had reason to doubt the efficacy" of the process advocated by Dr. Blyth. Next Dr. Broadbent points out, from his exceptional experience, that the "process" is practically unattainable, except in hospitals and the houses of the wealthier classes, and even there is apt to fail in making the convalescents harmless. Then Dr. Mahomed follows in the same vein as Dr. Broadbent, and insists, also from exceptional experience of scarlet fever, upon the prime necessity of "isolation" of cases. Lastly, Dr. W. Squire steps into the fray, refusing to be content with anything short of a quarantine (and a *real* one, to boot) of forty days for convalescents from scarlet fever.

What but bewilderment to the public can arise from a discussion of this sort? They can form no correct judgment of the respective values of the several statements of the writers, and what must be the general result but to engender a doubt both in households and among sanitary authorities of the value of "isolation" as a precaution against the extension of scarlet fever. To the householder it suggests an escape from an extremely irksome measure, and to the sanitary authority an escape from expenditure upon infectious disease hospitals. In the latter case it is difficult to exaggerate the mischievousness which might thus arise from the hasty publication of a suggestion which, at least, should have been supported by evidence having some proportion to the magnitude of the issues it involved. At present the suggestion, as a public health one, is directly opposed to existing experience. If subsequently it should be shown that there are stronger grounds for its acceptance than are now apparent, no one would welcome it more than ourselves. But there are pathological and clinical considerations to be dealt with which must be discussed in other places than the public press before we can reasonably indulge in such a prospect. The question as to the "laying" of scarlatinal dust as a mode of preventing the extension of scarlet fever still remains as it was stated in the well-known memorandum of the Local Government Board, issued first under the signature of Mr. John Simon—viz., "It is believed that the dispersion of contagious dust from the patient's skin is impeded by keeping his entire body (including limbs and head and face) constantly anointed with oil or other grease; and some practitioners also believe this treatment to be of advantage to the patient himself. When the patient's convalescence is complete, the final disinfection of his surface should be effected by warm baths (with abundant soap), taken on three or four successive days, till no trace of roughness of the skin remains. Not until this has been done, nor without the greatest care that the clothes are clean and free from infection, should the patient, however slight may have been the attack, be allowed to associate with persons susceptible of scarlatina."

It would be hard to say whether the Council of the Royal College of Surgeons or the profession is to be the more congratulated on the announcement we were able to publish last week—namely, that the Council has resolved to discontinue, from and after the 31st of December next, the preliminary examination at present conducted under its authority by the College of Preceptors, and also to improve the professional examinations for the diplomas of Member and Fellow by extending the examination in medicine and making midwifery a compulsory subject of examination on and after the 1st of next January. The importance and significance of these resolutions can only be properly appreciated by those who have studied the behaviour of the various Corporations throughout the United Kingdom towards all questions of medical education and reform. The Council of the Royal College of Surgeons, though long unyielding and at times resentful, has, more perhaps than any other similar institution during the past ten years, manifested a susceptibility if not a readiness to be influenced by outside opinion. The formation of the Board of Examiners in Anatomy and Physiology, separate from the Court of Examiners in Surgery, was an enormous concession to the spirit of modern times, and in its turn smoothed the way for the further adaptation of dividing the Board into examiners in anatomy and examiners in physiology. This was well as far as it went; but, in spite of what the Council had done, there were still two serious grounds of complaint. The preliminary examination was notoriously inadequate, and the chief professional examination was seriously incomplete in so far as the diploma acquired through it was held to be sufficient to place anyone upon the Medical Register as a legally qualified practitioner. A person furnished with the diploma of Member of the College might legally engage in general practice, though he had been submitted to the most meagre examination in medicine, and had not been examined at all in midwifery. Had it not been for the long-cherished hope of a Conjoint Scheme it is difficult to imagine that such a scandal would have been allowed to continue. All this is now to be changed. The responsibility of the preliminary education of the medical students will henceforth devolve entirely upon the General Medical Council. It, therefore, becomes imperative upon this body not only to see that the wish expressed by the Council of the Royal College of Surgeons is carried out—namely, that the preliminary examinations should be held at the most convenient times and places,—but also to take special pains that the examinations accepted in lieu of those held by the College shall be thorough and comprehensive. The profession and the public alike will have cause of complaint if the largest and most important corporation should in the interests of education give up its preliminary examinations while minor ones are allowed to continue theirs. It is quite as important to guard the side entrances as the main portals. There can be no uniformity in the requirements of preliminary education until these examinations are conducted under the authority and supervision of one central body, like the General Medical Council. The general educational and examining bodies should be entrusted with the management of the examinations, and the General Medical Council should define the regulations and requirements relating thereto. In this way the General Council may control preliminary education, and indirectly prescribe and determine its character.

THE occasion of the distribution of prizes at the Ceylon Medical School, on Nov. 29th last, was rendered additionally interesting by its being made the celebration of the completion of the Koch Memorial Clock Tower, which now stands prominently forward in front of the De Saysa Museum and Hospital. Shortly after the lamented death in 1877, from accident, of Dr. Koch, Principal of the Medical School and Surgeon to the General Hospital, the members of the Civil Medical Department determined to raise a subscription among themselves to found prizes for operative surgery in memory of their deceased friend. Funds for these prizes having, however, been forthcoming from another source, the sum collected was increased by contributions from the general public, with the result of obtaining sufficient for the erection of the Clock Tower above named.

Annotations.

"Ne quid nimis."

DUNDEE COLLEGE AND ST. ANDREWS UNIVERSITY.

MUCH support is given on all hands to the proposal to which we adverted two weeks ago, that Dundee College and St. Andrews University should be amalgamated; and it is not simple affiliation which is aimed at, but actual migration of the University, in the literal sense of the word, to Dundee. It is urged that St. Andrews is unable to keep up its state respectably, and this is not untrue. The salaries of its professors in 1876–77 ranged from £160 to £585, and since that time, owing to sundry unfavourable circumstances, these emoluments have greatly fallen off. The liberal endowment of the College would renew the youth of our venerable University—a benefit which the latter would repay by the prestige which it would certainly impart to the younger institution. St. Andrews men are specially indignant at another scheme which has been hinted at—that the new college should be affiliated to Edinburgh University; this would mean total extinction for "little St. Andrews" at no very distant date. It is pointed out by some in support of the scheme for simple affiliation with St. Andrews, that such a project would only restore that University to its former dignity; as from 1537 to 1747 the University of St. Andrews contained three colleges, while at present it possesses but two. Unlike the other Scotch Universities, St. Andrews Colleges form distinct corporations from the University, have their own principals, and administer their own property—an arrangement which would favour the connexion of the proposed College with the University. After all the hard wooing that has been going on it would be singular if Dundee men preferred single blessedness, and a house and name of their own.

RESPONSIBILITY AND DISCRETION OF CORONERS.

PENDING the completion of the case, and the decision in the matter of the important application to the Lord Chancellor to dismiss the coroner for West Surrey, it is eminently undesirable to discuss the personal aspects of the case. One of the points raised by the inquiry is, however, of general importance in connexion with the present unsatisfactory state of legislation affecting coroners and their duties. The regulations which guide or control the responsibility and discretion of coroners in their decision as to the necessity for holding inquests, if any exist, are so loose and unsatisfactory as seriously to diminish the value of the coroner's office as a social protection from various forms of crime and criminal neglect. The very remarkable variations in the proportions of inquests held in different towns and counties, so often alluded to by the Registrar-General in his periodical returns, sufficiently point the different interpretation which different coroners put on the present state of the law with regard to holding inquests, even in case of deaths resulting from violence. This uncertainty in the practice of coroners creates innumerable apparent hardships for the public, apart from the manifest dangers arising from the possible neglect to hold necessary inquests. It is evident from the discussion which took place on this point, on the first day's hearing of the application above referred to, that in the opinion of the Lord Chancellor a coroner should have the weightiest of reasons for refusing to hold an inquest in the case of a death from violence which is brought under his notice. The well-known case of Sir Charles Lyell somewhat added to the difficulty and uncertainty in the exercis of the discretion of coroners in those cases of death from violence in which a certificate of a registered medical practitioner is forthcoming. While, however, a legal certificate of the cause of such a death may afford ground for the decision that an inquest is unnecessary, it would be impossible to accept such a certificate as a necessary bar to the holding of an inquest. The responsibility of refusing to hold an inquest in the case of a death relating to which no medical certificate is forthcoming is, however, so grave, that we doubt whether it should rest with coroners. An examination of the death register for some parts of England and Wales, especially in some of the home counties—Kent, for example—should carry conviction that the time has come for some more definite legislation limiting the discretion of coroners as to the necessity for holding inquests. It may be hoped that the present inquiry may help in this direction.

THE CONTAGIOUSNESS OF GLANDERS.

GLANDERS is now so prevalent throughout the country, and exists to such an alarming extent in London, that any additional evidence we can obtain as to the manner in which it is propagated must be of value. It is not, perhaps, going beyond the mark to assert that not one-half of the cases of this horrible and fatal disorder are reported to the Government; nor is it the less true that proper sanitary measures are very seldom adopted for its suppression. And it is greatly to be feared that the malady is mistaken for other diseased conditions, especially pyæmia, and that sick animals are allowed to live for weeks or months among others, to the great danger of not only these, but their human attendants. It has long been known that glanders is an inoculable disease, and that it could also be produced by transfusing blood from a diseased to a healthy horse or ass, as well as by introducing the virus contained in the nasal discharge into the stomach. It is possible that all the secretions and excretions are more or less infective, the peculiar muco-purulent fluid thrown off by the Schneiderian membrane probably being most active. This discharge has been blamed as rendering the public watering-troughs a source of danger, the fluid passing into the water when glandered horses are allowed to quench their thirst at these valuable conveniences. It has been objected to this notion, that the discharge being heavier than water, falls to the bottom of the trough, and not being readily diffusible, is not likely to be swallowed by other horses watered there. This argument had a certain amount of plausibility, and the friends of the public water-trough movement availed themselves of it when the troughs were accused of being largely instrumental in disseminating the disease.

From a note presented to the Académie des Sciences by Professor Galtier, of the Lyons Veterinary School, it appears that he has been successful in transmitting the disease to an ass, by the hypodermic injection of saliva from a glandered horse. We know that the virulent germs find admission not only through a wound or abrasion, or a thin mucous membrane, such as the conjunctiva, but also by the digestive organs. Saliva readily mixes with water, and those who have watched horses drinking will have remarked that some of the water taken into the mouth escapes by the commissures of the lips and falls back into the trough or bucket; and when drinking has been completed, a certain quantity which has not been swallowed is also returned; so that a glandered horse may largely contaminate the water in a trough with his saliva. Not only this, but when horses drink greedily, it often happens that a portion of the water is returned through the nostrils; so that the nasal, as well as the salivary secretion, may find its way into the mass of water which healthy horses subsequently swallow.

Galtier's experiments also go to show that the glander virus loses its activity when the matters which contain it, whether liquids or tissues, have been completely desiccated for fifteen days. Thorough ventilation of buildings which have been tenanted by glandered horses is, therefore, a very effective means of purifying them.

The diagnosis of glanders is sometimes very difficult, if not impossible, without having recourse to test inoculation; and the animal usually inoculated is the ass, that creature being not only less costly for this purpose, but also more easily infected than the equine species. It is still costly, however, and being large and somewhat expensive to keep during the experiment, other more convenient animals have been proposed for substitution. The rabbit is one of these, but, as M. Colin has shown in the experiments which we described a fortnight ago, it cannot be relied upon as a test animal.

THE CLINICAL SOCIETY.

The meeting of the Clinical Society on the 14th instant was very numerously attended. The ballot for the election of officers and Council for the ensuing year took place, and the following gentlemen were duly chosen:—President: Joseph Lister, D.C.L., LL.D., F.R.S. Vice-Presidents: Drs. William Henry Broadbent, Thomas Buzzard, and Andrew Clark, and Messrs. Brudenell Carter, George Lawson, and Thomas Smith. Treasurer: Mr. Christopher Heath. Council: Drs. Julius Althaus, Thomas Barlow, John Cavafy, James Frederick Goodhart, William Richard Gowers, William Smith Greenfield, George Vivian Poore, Edmund Symes Thompson, Alfred Wiltshire, I. Burney Yeo, Leonard William Sedgwick, and Edwin T. Watkins, and Messrs. Marcus Beck, William Bartlett Dalby, Henry Greenway Howse, Charles Macnamara, F. Howard Marsh, Edward Nettleship, William F. Teevan, and William Spencer Watson. Honorary Secretaries: Dr. Frederick Taylor and Mr. J. Warrington Haward.

The report of the Council was read by the hon. sec., Mr. Howard Marsh, and its reception moved by Dr. Douglas Powell, seconded by Mr. Barker. The President announced that the Council had passed some regulations regarding the preparation and reading of papers, which would shortly be in the hands of the members. Dr. Andrew Clark then proposed a vote of thanks to the retiring President, Dr. E. Headlam Greenhow, F.R.S., for his invaluable services during his term of office. Dr. Clark's motion, which was prefaced by some highly eulogistic remarks, was seconded by Mr. Morrant Baker, and carried by acclamation. Dr. Greenhow, in acknowledging the vote, said that the success of the meetings of the Society was largely owing to the admirable manner in which the hon. secretaries, Dr. Taylor and Mr. Marsh, had performed their duties. He added that he had endeavoured to encourage reports by committees, two of which had still to be presented, one of which—viz., that on the Treatment of Hip Disease—was on the point of completion. On the motion of Dr. Ord, seconded by Mr. Godlee, a vote of thanks was accorded to the retiring Vice-Presidents and other members of the Council, which was acknowledged by Mr. Hulke. Mr. Macnamara then proposed, and Dr. Burney Yeo seconded, a vote of thanks to Mr. Howard Marsh, the retiring secretary, which was cordially carried.

THE KINDERGARTEN SYSTEM.

AMONGST those interested in the education of children, there are probably not two opinions as to the merits of this system, which is gradually becoming known and appreciated in this country. There is, however, a practical difficulty in its application. The education of a child should begin from the moment it takes notice, and for this purpose it is, of course, necessary that those who have charge of the infant should possess the requisite knowledge. When we reflect upon the position of the nurse in regard to our children, the sway which she exercises over them for many hours in the day and night, we must feel how little is ordinarily known of the competence of those we employ for so responsible a charge. It is not so much the willingness of the nurse to do right that is in question as her knowledge of the principles upon which the early education of a child should be conducted. It is not so long since any old woman, who was too decrepit to do anything else for her living, was considered to possess in perfection the requisites for a sick nurse. The art of cooking was apparently supposed to be inborn in individuals who aspired to the culinary department of domestic service. A tradesman who had failed in his business was as certain to set up a preparatory school as a military man on quitting his profession took to the wine trade. And so, even at the present day, any woman who declares her proficiency is supposed to be endowed with the power of directing the education of a child, the right conduct of which will probably have more influence upon its future happiness than any other circumstance, except the qualities which it possesses by inheritance. It is time that something was done to arrest the present anomalous state of things.

THE MUSCLES IN PHTHISIS.

TWO years ago Fränkel, observing how many patients with phthisis presented hoarseness without any corresponding laryngoscopic changes, investigated the condition of the laryngeal muscles in order to ascertain whether any changes in them explained the symptom. In a considerable number of cases, both those in which there were ulcerations in the mucous membrane and those in which the naked-eye appearances were normal, he found constantly an atrophy of the striated muscles. The contractile substance was broken up, the striation indistinct, and a granular opacity had replaced the normal translucence, while in the fibres in which the process was more advanced there was an actual molecular destruction, and ultimate disappearance of the proper tissue. The connective tissue between the primitive bundles also presented a marked cell-formation, and the muscle nuclei were so increased in number as to constitute cellular sheaths to the fibres. This increase seemed to have produced additional damage to the muscular fibres, since these in places were apparently destroyed by the pressure of the groups of cells.

These observations have been confirmed by a series of investigations on forty phthisical subjects by Dr. Posadsky of St. Petersburg, which show that the changes found by Fränkel in the muscles of the larynx exist also in other muscles examined—viz., those of the upper and lower limbs, flexors and extensors, the intercostal muscles, and the diaphragm. The muscular fibres were pale, and exceedingly friable, so that they broke across with undue readiness, and could with difficulty be separated into longitudinal fibrils. This was found in two-thirds of the cases; in the remaining third the muscles were perfectly healthy. The microscope showed a granular degeneration of the fibres in all cases in which the naked-eye changes were observed. In many cases the transverse striation had entirely disappeared. Many of the fibres were strikingly narrowed, and some empty sarcolemma sheaths were seen. Fibres which were not degenerated also showed the tendency to break up into transverse segments which had been noted in the naked-eye examination. Why these changes should be so conspicuous in some cases of phthisis and absent in others it is difficult to say, since the cases with and those without the change presented nearly the same conditions and nearly the same visceral changes. The changes in the interstitial connective tissue described by Fränkel were not found by Posadsky.

FOREIGNERS IN THE MARSEILLES HOSPITALS.

AT the recent sittings of the Marseilles Municipal Council an important discussion arose from the increased expenditure due to the very large proportion of aliens who sought and obtained medical assistance and treatment in the town hospitals. The question suggested itself as to whether it was fair to tax the inhabitants of Marseilles for the maintenance of these numerous strangers. It is estimated that as many as half the patients treated in the Marseilles hospitals are foreigners, and these latter, for the most part, are Italians. On the other hand, it is argued that as the Marseillais cannot, or will not, do the heavier work, and prefer inviting Italian labourers to toil in the docks and at the new buildings which embellish the town, the consequences must be patiently borne. Further, so long as the Italian labourer preserves his health, he aids, by his work and his consumption of taxed provisions, to the wealth and income of the town. There is an Italian benevolent society, as well as an English sailor's home, at Marseilles, and both have rendered great services, but as yet neither nationality has been able to open a hospital for its own people, nor should this be necessary if a true system of reciprocity existed amongst nations. It is precisely the presumed absence of such reciprocity which in any way justifies the complaints of the French against the Italians. It was averred before the municipal council that while it suffices for an Italian to prove that he is ill to obtain admittance to a Marseilles hospital, a French sailor or workman would have considerable difficulty in obtaining similar assistance in an Italian port. This is due, not to any lack of generosity or hospitality on the part of the Italians, but simply that their hospitals are in many instances constituted on a totally different basis. Many of the Italian hospitals are endowed by pious founders, who imposed regulations which, though in no way controlled by the Legislature, must be observed. These charters sometimes exclude strangers from the benefits of the charity, and it can be readily understood that the State has not created national hospitals where there are private hospitals that answer to nearly all the requirements of the locality. These old foundations, many dating back some centuries, no longer meet the exigencies of international intercourse brought about by modern civilisation. They must either be reformed or new wings added free from the trammels imposed by the original donors. But to ensure perfect reciprocity an international treaty should be concluded between the two countries, and its provisions might probably be extended with considerable advantage to other nationalities. That the claims of humanity override all frontier divisions is a principle that the impressionable and poetic people of Italy will readily admit.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

WE are glad to be able to state that the guarantee fund for this exhibition shows every sign of being sufficient, and there can be little doubt that the scheme will be proceeded with. Among the chief guarantors are Messrs. Barron, Squire, and Co., and Messrs. Maw, Son, and Thompson, who, as well as Mr. Twining of Twickenham, and Mr. Noble of Henley-on-Thames, have each guaranteed £50. Among the other guarantors are Messrs. Doulton and Co., W. Eassie, Esq., C.E., the Sanitary Assurance Association, the President of the College of Surgeons, Captain Douglas Galton, Mr. Rogers Field, Dr. Steele of Guy's, Dr. Corfield, Mr. G. Godwin, Messrs. Benham and Son, and many others. The amount already guaranteed approaches £700. Many of the guarantors have advanced various sums towards the preliminary expenses, and it is hoped that others will do the same, as these expenses are necessarily not trivial in an undertaking of such magnitude. It is not the intention of the Exhibition

Committee to appeal to members of the profession to assist the guarantee, because it is felt that the expenses of the Congress itself have been, and will be, considerable, and that it would be unfair to make any further appeal to them. Any voluntary assistance, however, will be gladly received, and it is trusted that all who feel disposed to help the committee will do so, for it is evident that the larger the sum guaranteed the less will be the proportionate part to be paid by each guarantor in case the exhibition should not be a success financially.

The exhibition will be divided into a medical section and a sanitary section. The medical section will include whatever is of use in the treatment of the sick and wounded, and in the detection of disease, as well as a class devoted to appliances used in teaching medicine — such as books, diagrams, models, &c. The sanitary section will comprise domestic and hospital architecture; ventilation, lighting, warming; water-closets, &c.; water supply and filtration; health resorts and sanatoria. It will be seen therefore that the scope of the exhibition is wide, and it is highly probable that the 70,000 square feet of area which is the maximum that can be obtained at South Kensington will be found to be none too much. The Exhibition Committee is not yet complete, but at present it is composed of Mr. Erichsen as chairman, Mr. Berkeley Hill as treasurer, Dr. Corfield, Mr. Eassie, Mr. R. Field, Mr. G. Godwin, F.R.S., Mr. W. A. Meredith, M.B., M.R.C.S., Dr. Poore, Mr. E. C. Robins, F.S.A., Mr. Roger Smith, F.R.I.B.A., and Dr. Steele. Mr. Mark H. Judge is the secretary; and we are asked to state that all communications should be addressed to "The Secretary of the Exhibition Committee, Parkes Museum of Hygiene, University College, Gower-street, W.C."

THE CATGUT LIGATURE.

There is no part of the surgical practice instituted by Mr. Lister that has excited more interest and attention than his reintroduction of an animal ligature. In spite of many experiments, and much clinical experience, the opinion of the profession is far from unanimous in favour of carbolised catgut. Imperfections in its preparation, and its use in unsuitable cases, may explain a part, if not all, of the failures and accidents that have attended its employment, but its most ardent advocates, we believe, will grant that some improvement in its preparation is still demanded. A recent contribution to our knowledge of the action of catgut ligatures is found in a memoir entitled "Contribution à l'Étude de la Ligature dans le Traitement des Anévrismes," by Dr. G. F. Arnaud. Dr. Arnaud ligatured the carotid or femoral artery of dogs fourteen times, using carbolised catgut, and examined the parts from four to sixteen days afterwards. In nine cases the ligature had entirely disappeared, or was only scarcely appreciable; in two it was partially absorbed, with destruction of the knot; and in three it was little altered. In one of the latter only four days had elapsed from the application of the ligature, which may be held to account for the fact; in the other two, examined on the ninth and sixteenth days respectively, there was an absence of inflammatory reaction and clot, and the ligature was encysted, while for its absorption a rather abundant outpouring of lymph, or development of "granulations," is held to be necessary. In twelve of these cases the outer coat of the artery was found quite unaltered, not having been severed by the ligature; in two it was partially ulcerated, in neither case completely. In twelve cases, the inner and middle coats of the vessel were completely divided, as happens in the use of a silk or hempen thread; in one they were entire, and in one other it was doubtful whether they were partly divided or not. The clot, where not absorbed, was very small, and the obliteration of the artery was complete and firm. Senftleben has stated that internal clot rarely forms with catgut ligatures, but the evidence of these experiments, as well as of others, points to an opposite conclusion. Arnaud concludes that the effect of catgut on the artery is like that of hemp, except—a most important exception—that the outer coat is not ulcerated, the knot of the ligature softening before that occurs. It was noticed, in cases where a strand of catgut was left in the tract of the wound, that there was much more active cell-growth round the ligature than around these strands, with corresponding difference in the rate of absorption. The "absorption" of catgut is thus again fully corroborated, and still more the fact that the use of catgut ligatures is not necessarily followed by the complete severance of the artery, with the attendant risk of secondary hæmorrhage, as always follows the use of hemp or silk.

THE SNOW.

A contemporary complains that, while objecting to the measures commonly adopted in dealing with a heavy fall of snow, we do not suggest a specific method of procedure. It is our function, as the organ of medical opinion, to point out dangers to health and life or limb, and it seems decorous to leave the initiation of social reforms to our lay coadjutors. If, however, a suggestion be desired, here is one. On the next occasion of a heavy fall of snow, which seems likely to continue or lie, let the experiment be tried of simply rolling it with a moderately heavy and rough roller, so as to make a firm and roughened road. This will furnish an easy surface for wheels or runners, and the roughed shoes of horses will be, at the same time, able to obtain a hold of the ground sufficient to prevent their slipping. Moreever, when the thaw takes place it will be gradual, and instead of making the whole roadway a quagmire, it will be only commonly wet. As to the foot-paths, let them either be wholly and properly cleared by the able-bodied poor of each parish, or simply strewed with sand or ashes. The present mode of partial scraping produces a surface which is so treacherous as to occasion most of the accidents that occur to the unwary pedestrian.

PEPTONE IN PUS.

Peptone was once supposed to be exclusively a product of digestion. Whether it is so or not, its distribution has been found to be very extensive through the body. Its presence in pus has just been demonstrated by Hofmeister. A litre and a half of fresh pus removed from the thorax by paracentesis was taken, the albumen was removed by heat and oxide of lead. The lead was separated by hydrochloric acid and the peptone precipitated from the acid filtrate by phospho-tungstic acid. Thus obtained and separated, it was found to be in all respects identical with ordinary peptone, and when heated to 160° C. it passed into albumen. In composition it appeared to be nearly identical with casein peptone. In order to estimate the amount of peptone, the albumen was removed, and the polarising action of the liquid was ascertained. The peptone was found to vary between ·367 and 1·275 grammes in 100 cubic centimetres, and to be greater, the thicker the pus. In one instance it was found that the amount of peptone in the upper layers of pus was less than in the lower layers. In another case it was ascertained that the serum contained no peptone, while the pus-corpuscles contained abundance. A similar result was obtained with pus diluted with saline solution, and then filtered. The residue contained from two to seven times as much peptone as the filtrate. But if the process of filtration lasts a long time, it may happen that the amount of pus in the filtrate is as great as in the original pus. This is explained by the circumstance that the pus-corpuscles, in their death, give up their peptone. The same effect is produced by dilute caustic soda. By the destruction of pus cells large quantities of peptone may be liberated, and thus pepton-uria may arise.

STREET-VICTUALLING.

It would be a seasonable enterprise for any purveyor of food and drink to send into the public thoroughfares, for the convenience of the working classes and the industrial community generally, hand-carts fitted with apparatus for the supply of hot coffee, tea, and food suitable for hasty dinners. If hot food and drinks could be sold in the streets at a small cost in London, as they are in many of the provincial cities and towns, a good trade might be carried on, and a considerable personal service rendered. At present hot chestnuts by day and hot potatoes in the evening are the only eatables to be purchased. Hundreds of hurried or poor foot-passengers would hail such appliances as a means of health, and they would form one of the most direct, and, as we believe, effective, agencies for the avoidance of a common form and cause of drunkenness.

POST-MORTEM EMPHYSEMA FROM GASTRIC ULCER.

Among the causes of subcutaneous emphysema ulcer of the stomach is one of the rarest. An instance has, however, lately been reported by Poensgen in the *Deutsches Archiv für Klin. Med.* The patient was a man aged thirty-seven years, who had for three years presented the symptoms of gastric ulcer. He had been treated by washing out the stomach by a douche, and was relieved. A fresh attack of vomiting occurred, and he died suddenly on his way to the hospital. A short time after his death, the abdomen, chest, neck, head, face, arms, and the left leg were gradually invaded by enormous subcutaneous emphysema, which was also found after death in the connective tissue of the mediastinum and beneath the peritoneum. In the smaller curvature the wall of the stomach was perforated by an ulcer, and on the inner surface of the abdominal wall was another ulcer, which had apparently corresponded to the perforation in the stomach, and through it the gas from within that organ had seemingly escaped into the cellular tissue.

SUDDEN ILLNESS AMONGST THE POOR, AND MEDICAL ATTENDANCE.

There is a very comfortable doctrine abroad that doctors are at everybody's service in an emergency, and that they are bound to rise from their beds and go to a distant alley to save a life or ease a pain, without the least prospect of recompense. But why is such mercy to be shown only by doctors? Why does not the public share with doctors the cost and the credit of such service? It is society's duty, not that of any single profession, to see that no human creature, however poor, dies without medical aid. A country like this should make provision for the emergencies of its poor, and not throw the whole onus on the much enduring and little paid members of our profession.

We are informed that the Oxford Examination for the Radcliffe Travelling Fellowship will be holden in Lent Term, commencing on Tuesday, February 8th, at 10 A.M., in the Medical Department of the Museum. Candidates are requested to send their names to the Radcliffe Librarian, Museum, on or before February 1st.

We are glad to hear that Her Majesty's Office of Works has entrusted Mr. Waterer with the providing and planting of a large number of Rhododendrons and Azaleas in Hyde Park during the approaching season.

Professor Huxley has been appointed to the Inspectorship of Fisheries, vacant by the death of Mr. Frank Buckland. The duties connected with this post are not, we understand, of so engrossing a character as to necessitate his withdrawal from the more important of his other scientific engagements.

The following resolution was passed at a meeting of the Norwich Medico-Chirurgical Society on Jan. 4th, 1881:—"That this meeting, reprobating the systematic exclusion of the medical officers from the government of hospitals, tenders its sympathy to the staff of Guy's Hospital in the present crisis."

A meeting of Convocation of the University of London was summoned for Tuesday last, but in consequence of the inclement weather it was decided by the few members present to adjourn the business on the agenda-sheet until the meetings, which will be held as usual, in May.

At Rome, on the 16th inst., the new Anatomico-Physiological Institute in the Via Quattro Fontane was opened before a numerous and distinguished audience by Professors Tommasi-Crudeli and Moleschott, of whose addresses we shall give some account next week.

The president, vice-presidents, and council of the Royal College of Surgeons have just issued invitations for a large party of distinguished visitors to the Hunterian festival to be held on the 14th prox. after the delivery of the biennial oration by Mr. Luther Holden.

The death is announced of Dr. David P. Smith, Professor of Surgery in the Yale Medical School, and one of the most distinguished surgeons in the State of New York.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

THE "METROPOLITAN" AND "THE LANCET."

Our esteemed contemporary, the *Metropolitan*, has taken us to task, in no unkindly spirit, for having spoken somewhat disparagingly of local self-government in the metropolis with reference to small-pox and vaccination. He objects to our phrase, the "genius of muddle," as applied to the local bodies in this respect, and thinks it unwarranted; and he evidently thinks that the hard language which we apply to the Local Government Board for its doings in the present small-pox crisis is irreconcilable with our observations on the local administrative bodies. If, in face of a growing epidemic of small-pox, its own reports of the shortcomings of the vaccination authorities in the East-end, the want of proper co-operation between the vaccination authorities and the sanitary authorities, the state of question as to small-pox hospitals and the relations of the sanitary authorities thereto, our contemporary objects to the term "muddle," we shall not quarrel with him so long as the facts and the causes productive of them are recognised. But our contemporary, we think, furnishes an illustration of our observations last week of people having been led astray from the fundamental element in our means for preservation from small-pox on the by-path of hospital-isolation in small-pox, by the prominence which has been given of late to this question. He had probably not in mind, as we had when we wrote, the primary importance of vaccination as *the* safeguard against small-pox. Now, as far as public vaccination is concerned, the local poor-law authorities are responsible for the due and efficient carrying out of vaccination. In this respect, we gather from the columns of our contemporary several of the Boards of Guardians in the East end of London have been peculiarly remiss in the interval between the last epidemic extension of small-pox and the present. We know well what the difficulties in carrying out vaccination in London are, particularly those enumerated by the Local Government Board; but we draw a somewhat different lesson from them than our contemporary appears to do. These difficulties call for greater and more unremitting care in the administration of the Vaccination Acts in London than they do elsewhere—than in places where they do not exist in the same magnitude; and they involve greater responsibility in the exercise of care. Local self-government has not fully justified itself in the metropolis in this matter, and until the citizens more generally see the grave concern, so far as small-pox is concerned, they have in exacting from their poor-law local representatives a somewhat higher conception of their duties as to vaccination *at the intervals of epidemics* than has hitherto prevailed, we must take our recurring small-pox epidemics, great and small, with such grace as we may.

PUBLIC HEALTH IN SCOTLAND.

The section devoted to public health of the "Thirty-fifth Annual Report of the Board of Supervision for the Relief of the Poor and of Public Health in Scotland, 1879-80," recently published, is devoted to a bare summary account of the particular administrative actions (mainly formal) which the Board has had to undertake during the year, to which the report refers. One of the causes which called for the action of the Board is novel: it refers to the refusal of a sanitary inspector (an equivalent to our inspector of nuisances) to enter a room in which a patient lying ill of "fever" lay, and into which it was presumably necessary that he should enter for the due performance of his duties, on the ground that he did not consider it his duty to do so. On this the Board called for a report from its medical officer, Dr. Littlejohn, on the subject; and observes, "We are aware that in some parts of the country an unreasonable and exaggerated dread of infection is entertained by the population, and we deemed it especially necessary that in places where such feelings exist the sanitary inspector should know what his duties are, and should discharge these duties faithfully. We transmitted a copy of Dr. Littlejohn's report to each local authority for their information and guidance; and we intimated that we were of opinion that every person holding the office of sanitary inspector must be prepared, in the due discharge of his duties, to enter the house or room in which cases of infection exist, as pointed out by Dr. Littlejohn." A copy of Dr. Littlejohn's useful report is given in the appendix to the Board's report.

THE SALE OF FOOD AND DRUGS ACT.

Dr. John Clark has published in a separate form the excellent lecture he gave on "Adulteration and the working of the 'Sale of Food and Drugs Act'" at the opening of the present session of the Glasgow Royal Infirmary School of Medicine. He describes briefly, but clearly, the results of THE LANCET Analytical Sanitary Commission, of the legislation which followed upon them in 1860, and of the various amendments of that legislation to the present time. He illustrates his lecture from the experience of Glasgow, shows the shortcomings in the administration of the Sale of Food and Drugs Act, especially in Scotland, and generally presents us with a readable and most interesting and instructive account of this important subject.

THE HAMPSTEAD SMALL-POX HOSPITAL.

The hearing of the appeal, Hill and others *v.* The Metropolitan Asylums Board, came before the House of Lords this week. The arguments were concluded, but their lordships took time to consider. We reserve comment until the judgment is made known.

A serious localised outbreak of scarlet fever is reported from Halifax, believed (but we learn on insufficient evidence) to be due to dissemination of the contagion of the disease in a milk-supply. A milker, it is reported, had pursued his duties of milking in one of the sources of supply to the implicated dairy while several of his children were suffering from scarlet fever.

The report of Mr. Peter de la Motte of the West London District School for the year 1880 shows on the whole a favourable condition of health among 700 and odd children there, and a comparatively low mortality (7·2 per 1000 per annum). Ophthalmia is spoken of as "the malignant enemy of the school," but is stated to be decreasing under present arrangements. Granular eyelids, however, are reported prevalent, and as requiring constant and careful watching in order to eliminate relapsing cases. The plan of isolating slight cases of ophthalmia is carefully carried out.

From a recent meeting of the Rural Sanitary Authority of the Isle of Wight we gather that the Authority begins to scent trouble from the Local Government Board in its existing arrangements for inspectors of nuisances and medical officers of health. Dr. Ballard's recent visit to the island has no doubt left a pretty clear impression upon the mind of the Authority there that the Local Government Board cannot permit the present arrangements to stand without somewhat peremptory interference. Dr. Ballard's report has not yet been made public.

The Local Government Board take exception to the payment of vaccination officers by fixed salaries, and not by fees per case. The Board state that in their experience the payments of these officers by results has produced the best effects. A proposition of the City of London Union Guardians to give their Vaccination Officer a yearly salary of £75 has not met with the approval of the Local Government Board, and the Guardians have been requested to reconsider the subject, with a view of fixing his remuneration on the fee system.

A Bill has been submitted to the House of Commons by Messrs. Magniac, Dodds, and others, to make provision for the better prevention of floods, and for the conservancy of rivers, but as it is rumoured the Government will bring in a Bill on the subject, we postpone comments until this Bill sees the light.

A Bill has been introduced into the House of Commons by Mr. Edmond Gray and others, to provide for the better Notification of Infectious Diseases in Ireland.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The unusually severe cold which prevailed during the latter part of last week did not seriously affect the recorded death-rate; the effect of this cold will appear in subsequent returns. In twenty of the largest English towns, estimated to contain in the middle of this year nearly a third of the entire population of England and Wales, 5093 births and 3444 deaths were registered last week. The births were 93 below, while the deaths exceeded by 187, the average weekly numbers during 1880. The deaths showed an increase of 336 upon the low number in the previous week. The annual death-rate, which had been equal to 23·7 and 21·3 per 1000 in the two preceding weeks, rose again to 23·6 last week. During last quarter the death-rate in these twenty towns averaged only 21·5 per 1000, against 25·0 and 24·2 in the corresponding periods of 1878 and 1879.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 398 and 401 in the two preceding weeks, declined last week to 383; they included 99 from scarlet fever, 90 from whooping-cough, 74 from measles, and 35 from fever, principally enteric. The annual death-rate from these zymotic diseases averaged 2·6 per 1000 in the twenty towns, among which it ranged from 0·7 both in Plymouth and in Newcastle-upon-Tyne, to 3·4 in Bristol and 3·8 in Salford. Scarlet fever showed the largest proportional fatality in Oldham, Norwich, and Bristol; measles in Salford and Brighton; and whooping-cough in Nottingham and Leeds. The deaths from fever (principally enteric) in the twenty towns, which had been 48 and 39 in the two previous weeks, further declined to 35 last week. Of the 19 fatal cases of diphtheria in the twenty towns, 12 occurred in London and 2 in Portsmouth. Small-pox caused 28 more deaths in London and its suburban districts, whereas no fatal case of this disease was recorded in any of the nineteen large provincial towns. The number of small-pox patients in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 447 in the eleven preceding weeks, further rose to 476 on Saturday last. The new cases of small-pox admitted to these hospitals, which had been 146 and 85 in the two preceding weeks, rose again to 118 last week. On Saturday last 27 patients were under treatment at the Highgate Small-pox Hospital, showing an increase of 3 upon the number at the end of the previous week.

The deaths referred to diseases of the respiratory organs in London, which had been 290, 353, and 363 in the three preceding weeks, further rose last week to 371; this increase, however, was remarkably small, considering the severe cold, and the number was no less than 111 below the corrected average for the corresponding week of the last ten years; 236 were attributed to bronchitis, and 95 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was only equal to 5·2 per 1000 in London, whereas in Liverpool the rate from the same diseases rose to 9·1 per 1000, and in Salford it was equal to 13·2.

In the twenty towns last week the causes of 101 deaths were not certified, either by a registered medical practitioner or by a coroner; these were equal to 2·9 per cent. of the total deaths. The proportion of uncertified deaths was equal to 2·0 per cent. in London, while it averaged 3·7 per cent. in the nineteen provincial towns. No uncertified deaths were registered either in Brighton, Portsmouth, Plymouth, Wolverhampton, Leicester, or Sunderland; while their proportion was largest in Norwich, Oldham, Sheffield, and Hull.

HEALTH OF DUBLIN.

The rate of mortality in Dublin again showed an increase last week. The annual rate of mortality from all causes in the city, which had been equal to 35·8 and 31·8 in the two preceding weeks, rose again to 35·1 last week. During last quarter the death-rate in the city averaged no less than 32·6 per 1000, against 20·9 in London and 21·8 in Edinburgh. The 224 deaths in Dublin last week showed an increase of 21 upon the number in the previous week, and included but 12, or little more than 5 per cent., which were referred to the seven principal zymotic diseases; the number of deaths from these diseases in the previous week was 28. The 12 deaths from zymotic diseases in Dublin last week included 8 which were referred to fever (comprising typhus, enteric, or typhoid, and simple continued), and a fatal case each of small-pox, scarlet fever, whooping-cough, and diarrhœa; no death resulted either from measles or diphtheria. The annual death-rate from these zymotic diseases did not exceed 1·9 per 1000 in Dublin last week, while in London it was equal to 2·9, and in Edinburgh 4·0; so low a death-rate from zymotic diseases in Dublin has not occurred for many months. The deaths referred to fever in Dublin, which had steadily increased from 7 to 13 in the four previous weeks, declined to 8 last week; these, however, were equal to an annual death-rate more than five times as high as the average rate from the same causes last week in the twenty large English towns. The deaths of elderly persons (aged upwards of sixty years) in Dublin, which had been 43 and 47 in the two previous weeks, further rose to 66 last week.

GROWTH OF POPULATION IN ENGLISH TOWNS.

Within three months the Census of 1881 will have been taken, and before the end of June we shall know with some approach to accuracy what is the present population not only of the whole country, but also of its chief towns. In the mean time, however, the Registrar-General has been at the necessity of estimating the population of our large towns to the middle of 1881, for the purpose of calculating the annual rates of mortality published in the Weekly and Quarterly Returns. It is needless to say that these estimates are based for the most part upon the assumption that the rate of increase of population since 1871 has been the same as that which prevailed during the ten years 1861–71. The estimated population of the twenty towns, in the middle of this year, amounts to more than seven and a half millions of persons, and exceeds by nearly 120,000 the estimate for the middle of 1880. The excess of births over deaths in these twenty towns during last year was scarcely more than a hundred thousand, and it becomes a matter of conjecture whether the population in these towns was raised during the past year of commercial depression by the aggregation of nearly 20,000 immigrants. The probability is that the Census returns for many of our large towns will show that the increase of population during the decade just ended has been at a lower rate than that which prevailed in the preceding ten years; this would cause the Registrar-General's estimates of their present population to be in excess of the true numbers. In Sheffield, for instance, based upon the rate of increase during the ten years 1861–71, it is estimated that the gain to the population during 1880 was more than 8000, of which little more than 4000 is accounted for by excess of births over deaths. Those who know the severe period of depression from which Sheffield has recently suffered will scarcely be inclined to believe that the population of that borough was increased by nearly 4000 persons during 1880 through the excess of immigration over emigration. The population of Bristol and of some other towns is probably also over-estimated from the same cause. These doubts will be set at rest by the approaching Census, but it is much to be regretted that the value of the vital statistics for our largest towns, which are very properly attracting increased attention year by year, should be depreciated by the want of more trustworthy information as to population than can be derived from a decennial Census.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

THE SEWAGE OF PARIS.

Dr. Guéneau de Mussy has presented to the Society of Public Medicine of Paris, in the name of a commission of the Society, a report on the removal of night-soil from the habitations of Paris. The report recommends that it be made obligatory to introduce a water-supply into each house proportionate to the number of occupants; that properly constructed *cabinets d'aisance* should be required; that water should be readily accessible in the *cabinets d'aisance*; that wherever possible the *cabinet d'aisance* should communicate directly with a sewer; that where this is not practicable a movable receptacle should be had recourse to with a disinfectant to accompany each dejection; and, lastly, that "slops," as dejections, should pass directly to the sewers, a syphon-trap intervening. All the recommendations but that relating to "slops" were adopted by the Society. The modesty of the recommendations give a remarkable illustration of the shortcomings of Paris in these matters.

The Committee appointed by the Municipality of Paris to consider the question of the recent offensiveness of odour in the streets of that city, formed two sub-committees to consider respectively the question as it concerned sewers and cesspools (fixed and movable), and as it concerned depôts of offensive filth and manufactories concerned with the filth. The second sub-committee has reported, M. Aimé Girard, member of the Consultative Committee of Arts and Manufactures, acting as reporter. The recommendations of the sub-committee would do away with all depôts of filth within the city and its suburbs, and would subject to strict regulation the manner of dealing with filth in manufactories and the effluvium from the filth, so as to withdraw it from the free air, deodorise the solid matters, and destroy by fire offensive vapours.

PUBLIC HEALTH IN AUSTRALIA.

Although Australia has hitherto escaped the infection of cholera, it has not escaped the infection of Congresses. Melbourne has been having its "Social Science Congress," and, after the fashion of the home-bred examplar, a "health section" formed an integral portion of the Congress. According to our contemporary, the *Australian Medical Journal*, this section fell far short in its proceedings of what it had projected to do, and did not compare well, whether in material or in the exhibition of business capacity, with other sections. The address of the President, Dr. M'Crea, was not of a sort to put good heart into the meetings, and if, as he argued, the pioneers of public health in the Old World took a too warmly-coloured view of the public advantages to be derived from sanitary works and the labours of sanitary workers, he erred in the opposite direction in taking a too desponding view. It should have been obvious to him that his reference to the mortality statistics of Great Britain, and the vast expenditure of money in the last forty years, and the asserted inappreciable results therefrom, bristled with fallacies. A very different picture might have been drawn of the results of sanitary work in this country, at least equally free from too great hopefulness or too great despondence, and which would have given heart to the efforts now being made for the sanitary administration of Melbourne, and furnished the reasonable grounds upon which such efforts should be based, and which justify and incite Great Britain to add other millions to the millions already expended in the sanitary works and administration of the United Kingdom.

FEVER HOSPITAL FOR EDINBURGH.

No fever hospital worthy of the name exists at present in Edinburgh. It is true that the Infirmary managers, by arrangement with the Town Council, provide seventy-two beds in the old infirmary buildings for the accommodation of fever patients, no cases of this nature being treated in the new infirmary; but while this provision just serves to meet the requirements of the city for the moment, there being now sixty-five fever patients under treatment, it would prove very inadequate should an epidemic of even moderate dimensions break out, an event for which no great city can afford to be unprepared. A proposal has lately been made to purchase definitely the old infirmary buildings and convert them into a hospital for the treatment of infectious diseases. Many are of the opinion, however, that such hospital accommodation should be erected outside the city. Meanwhile Dr. Littlejohn, the medical officer of health, is preparing a report on the whole subject, which will soon be made public. This is clearly a matter which the Local Authority should undertake, as the Royal Infirmary has no funds of its own available for the purpose.

Diphtheria is reported to be raging at Mohilev, in Podolia. The Red Cross Society has organised seven sanitary detachments to meet the epidemic, each detachment consisting of a physician, two sub-surgeons, two sisters of charity, and numerous assistants.

Animal lymph has been introduced into Madras, and a regular depôt has been established, for the maintenance of which the Government has sanctioned a monthly allowance of 100 rupees.

Small-pox is stated to have broken out in the General Hospital of Halifax, Nova Scotia, and the majority of the patients in one ward had been attacked by the disease.

THE SERVICES.

MEDICAL REINFORCEMENTS FOR THE TRANSVAAL.

In addition to the medical officers who are now on their way to the Cape, to strengthen the staff at the disposal of Deputy Surgeon-General Holloway, C.B., the Indian authorities have detailed twelve officers of the Army Medical Department to accompany the troops embarking at Bombay for service in the Transvaal. These should reach Durban, the port of disembarkation, early in February, and will be a welcome addition to the medical staff.

Brigade-Surgeon William Skeen, M.D., and Surgeon Espine C. R. Ward are with the force under Sir Owen Lanyon, at Prætoria.

Brigade-Surgeon Sampson Roch was unable through ill health to proceed to the Cape last week, for service in Natal.

Deputy Surgeon-General J. Crerar succeeds Deputy Surgeon-General J. B. St. Croix Crosse as medical officer of the Royal Military Asylum at Chelsea. Dr. Crosse having attained sixty-five years of age is placed on the retired list.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of Feb. 22nd, 1870, Surgeon William Sale Sandham has been placed on the retired list from the 7th inst. The following appointments have been made:—Staff-Surgeon Bradley Gregory to the *Druid*, vice Bett, deceased; Staff-Surgeon A. B. Trousdell, M.D., to the *Phœnix*, vice Gregory; Surgeon Henry Scanlan, to the *Rifleman;* Surgeon Robert M'Ivor, M.D., to the *Asia*, vice Scanlan.

THE Metropolitan Hospital Sunday will be June 19th; February 7th and 13th are fixed as the Hospital Sunday and Saturday for the Manchester and Sheffield medical charities; the 9th inst. will be the Liverpool Sunday Fund; and on the 30th collections will be made in all the churches in Sheffield and the neighbourhood for the local medical charities.—*Charity Record.*

Correspondence.

"Audi alteram partem."

AN EXPLANATION OF THE NATURE OF THE CONNEXION BETWEEN THROAT AFFECTIONS AND ACUTE RHEUMATISM.

To the Editor of THE LANCET.

SIR,—In his paper on the "Association of Affections of the Throat with Acute Rheumatism" (THE LANCET, Dec. 11th, 1880), Dr. Fowler offers no theory to account for the undoubted connexion between the two, further than to state that it is not "to be explained on the hypothesis of a merely casual connexion," and that he believes "that not unfrequently it [the tonsillitis] is an early manifestation of the same [rheumatic] diathesis."

Pending the publication of a paper which I have in course of preparation upon the same subject, in which I have independently observed the same fact during the last few years, I would like to point out briefly that *all rheumatic fever cases* are, in my opinion, of truly pyæmic origin. By adopting this theory, which to me seems the true explanation of its nature, both from a clinical and pathological point of view, we can at once understand why a suppurative affection of the throat is followed by so-called rheumatic fever.

My experience accords pretty closely with Dr. Fowler's in placing the proportion of cases of acute rheumatism preceded by an affection of the throat at from 70 to 80 per cent., and it follows most frequently, if not only, upon the throat affection, that may be called, for want of a better name, acute follicular tonsillitis, in which a kind of purulent exudation is formed in the tonsil, and struggles out through the follicular openings on its surface.

By the prevention of its free exit, absorption of the pus is facilitated through the lymphatic vessels passing between the tonsil and the lymph gland at the angle of the jaw. The lymphatic gland resents this intrusion, inflames, enlarges, and endeavours to arrest the passage of the poisonous material in its onward course to the blood. In the discharge of this function the gland is sometimes completely successful, and hence many cases (though the first step towards infection of the blood is taken) never produce the affection of the joints or other organs. In other cases this function of the gland is less completely successful; the gland being unable to render the absorbed pus innocuous, or extrude it by inflammation, it passes onward to join the general circulation, after being arrested in its passage for a period of from one to three or four weeks, or, as I have some reason to think in some rare cases, for a considerably longer period; whilst in other cases still, that occur in constitutions of a more lymphatic diathesis, in which the lymphatic vessels may be wider or more active in their absorptive powers, or the glands less discriminative or resentful of the intrusion of effete or poisonous matter, the blood infection is accomplished, if not *pari passu* with the throat affection, at a very short interval after its declension.

The remaining 20 to 30 per cent. of acute rheumatic cases which do not claim this particular origin, may be brought about by absorption of pus elements at other mucous membranes, such as in the ear in acute or chronic otorrhœa, in the urethra in acute or chronic gonorrhœa, at the anus (as in fistula); and failing these particular localities, the absorption of any collection of pus, however small and apparently trivial, situated either in the mucous lining of organs, or on the cutaneous envelope of the body, is sufficient, in my experience, to accomplish the same result.

The last case I attended followed upon a small abscess under the finger-nail, the whole of which was absorbed, to be followed at the interval of a fortnight by affections of both ankles, knees, wrists, and the right shoulder in succession, producing what would be called a typical case of rheumatic fever.

Thus it will be seen that absorption of pus elements may take place in localities very likely to be overlooked, at least so far as its connexion with the after-production of rheumatic fever is concerned, and this occurrence not being followed *immediately* by the usual symptoms of purulent infection of the system, but the after sequences following at a considerable interval in point of time, easily accounts for the connexion between the two, which is really of a *post hoc, propter hoc* nature, remaining thus far unrecognised.

My experience further goes to prove that following upon the absorption of the throat, or at the other localities indicated, the absorbed *materies morbi* in passing the round of the circulation may entirely miss the joints, and the force of the poison may then spend itself upon other fibrous and connective tissues, such as the parenchyma of the liver, producing icteric complications; of the lungs, producing patches of consolidation; upon the fibrous envelope of the heart and its valves, causing pericarditis and endocarditis; and more rarely upon the fibrous covering of bones, causing thickenings of the periosteum, and even necrosis of bone. As a result of this absorption any one of these sequences may occur separately in a given case, or any two or all of them may be combined together in the same case. Sometimes one joint only is affected, at others all the joints and the heart as well. I have also observed a few joints, the liver, and the heart attacked, on other occasions the liver and the lungs; and even the heart only, producing what might have been called idiopathic carditis; and in a rare case I have known the joints, the liver, the lungs, the heart, and spleen all involved.

In conclusion, I would remark that the beneficial action of such remedies as alkalies, salicylates, iron, &c., in rheumatic fever, goes far to render probable the truth of the theory that pus cells (modified or unmodified) in the blood is its real cause, and that by adopting this theory the beneficial action of these remedies is, I think, placed upon a more scientific basis.

I am, Sir, your obedient servant,

WM. STEWART, F.R.C.P.E.,

Barnsley, Dec. 21st, 1880. Honorary Surgeon, Beckett Hospital.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—I trust you will allow me space in your valuable journal to call the attention of your readers to the following case, in which Chian turpentine was administered daily for nearly four months with marked benefit, as shown by the relief obtained from all distressing symptoms, and in the fact that the poor sufferer's path to the grave was deprived of pain. In justice to Prof. Clay, I feel bound to record my experience.

Mrs. C——, aged fifty-four, the mother of a large family, consulted me in August last. She informed me that about five years previously a "tumour" (probably cancerous) had been removed from the top of her head by Mr. Pridgin Teale of Leeds. A year and a half after the operation she noticed that a similar growth was forming behind the right ear. This had gone on increasing in size until the time she put herself under me. On making examination I found she was in a frightful condition. There was a medullary cancer of a fungoid type behind the ear, about the size of a hen's egg. It had begun to break down, and there was a very great discharge of pus and blood; from the base of the ulcerated portion cauliflower-like growths were springing. The right side of the face was very œdematous, the eyelids so swollen that she could not open the eye. All the lymphatics of the neck, thorax, and right arm were thoroughly infiltrated with cancerous matter, and over the upper part of the sternum was a large suppurating patch the size of the hand. She had a severe cough, and expectorated pus freely, often dreading lest she should be suffocated. Her general health was quite broken down. Slept badly; appetite poor; suffered much pain, especially in the neck and chest; very weak; had much palpitation. I gave her relatives an unfavourable prognosis. Treatment adopted: a five-grain pill of Chian turpentine (made according to Prof. Clay's formula) three times daily, after meals. Finding that she could take this quantity well, at the end of three weeks I increased it to double—viz., two pills three times daily. I also prescribed a mixture containing in each dose three minims of solution of strychnine and five minims of solution of perchloride of iron twice daily, as suggested by Prof. Clay. She improved in general health, felt so strong that she was able to visit me until within five days of her death. Her appetite increased, and she was able to take plenty of nourishment. She slept well most of the night, lost the palpitation and suffocative breathing, and, most remarkable and pleasing of all, the pains left her and never returned. All her friends considered the last result of the treatment to be marvellous. The turpentine never produced nausea or diarrhœa. The local symptoms on the whole remain unchanged.

Now I am persuaded that this poor woman's life was prolonged and her sufferings relieved by the use of the Chian turpentine. I never expected to cure her, as all the lymphatics were so thoroughly affected. If, however, the case had been treated four or five years previously by the above method there would perhaps have been no return of the disease. Even supposing Prof. Clay has not introduced a remedy which will cure cancer, yet if a sufferer's life can be prolonged and all distressing symptoms removed and death robbed of terror and pain, surely he has done something to earn the gratitude of the profession and the public! Meantime I would advise a still more extended trial of this remedy. I am, Sir, yours truly,

Leeds, Jan. 10th, 1881. H. A. ALLBUTT, M.R.C.P.E.

STATISTICS OF OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—Although it may be, as a rule, undesirable to refer in your columns to statements made in the discussions which take place at any of our Societies, yet there are occasions when there is no escape from such a course for the sake of truth and justice. Such a one is the present.

At the last meeting of the Royal Medical and Chirurgical Society I submitted to the judgment of my professional brethren a question of professional etiquette. After referring to the fact that, at a former meeting, Mr. Thornton quoted my results in ovariotomy in the Samaritan Free Hospital for the year 1880 for the purpose of comparing them with his own, I used these words: "I think it is a most unusual proceeding, and one that, I am sure, will not meet with your approval, but rather deserves to be censured, when anyone refers to the statistics of a colleague before they have been published either by the hospital or by the operator himself." To this Mr. Thornton is reported by you to have replied that "the statistics he then quoted from Dr. Bantock had been *mostly* (the italics are mine) published by that gentleman in a letter to one of the medical journals." As I was obliged to leave the meeting almost immediately after I had spoken, I did not hear Mr. Thornton's remarks, and, therefore, now ask him, through you, for the reference to the particular letter on which he relies. I wish to put myself right with those of my professional brethren who may have read your report, but more especially with the Society, whose guest I had the honour and privilege of being on that occasion.

I am, Sir, your obedient servant,

GEO. GRANVILLE BANTOCK.

Granville-place, Portman-square, W., Jan. 15th, 1881.

THE NEW FORM OF GAG.

To the Editor of THE LANCET.

SIR,—Will you kindly allow us, in your next issue, to explain the reason why we claim any credit for the "improved ring catch," in Mr. T. Smith's new combined mouth-gag and tongue-depressor. Mr. Rose was certainly kind enough to leave with us one of his gags as a pattern; but the gag was found unnecessarily long, and projected from the mouth, so as to be inconveniently in the way in operating, and on any side movement of the patient's head against the pillow being unexpectedly made, it was likely to be knocked from between the teeth. To do away with the likelihood of this occurring we have made the *levers* or *arms considerably shorter*, and with a larger space between them; this has been found a great advantage, as there is no *loss of power*. This alteration required a different arrangement of the catch than that of Mr. Rose's, which is simply a ring passing over the plain steel arms, the contact with the plain metal surface only preventing slipping. To our gag, therefore, we added a series of notches, or hollows, into the catch, thus doing away with any possibility of any slipping, and the gag unfortunately collapsing during an operation. We shall be happy to show the advantage of the gag to anyone calling, or it can be seen in use at the Children's Hospital.

As regards Mr. Rose's remarks regarding the utility of the tongue-plate, Mr. Smith informs us, "that it answers exactly in depressing the tongue, leaving nothing more to be desired in the many cases it has been tried, and is sure it will be found satisfactory in mouth operations."

We are, Sir, your obedient servants,
Great Portland-street, Jan. 19th, 1881. Mayer & Meltzer.

To the Editor of The Lancet.

Sir,—Mr. Rose objects to the addition of the tongue-plate in Mr. T. Smith's new form of gag (for use in removal of tonsils and in staphyloraphy) on account of its being liable to cause inconvenience when an anæsthetic is used. In the operation for the removal of tonsils, where an anæsthetic certainly is not required, I have never found a gag desirable. A child does not generally give trouble in the removal of one tonsil if there be no previous display of instruments, and should it tightly close its mouth during the very short time occupied in putting the guillotine in order for the second tonsil, it is only necessary to compress its nostrils, and immediately the mouth is opened to push the instrument in sideways; then turning it round one has a gag and at the same time the guillotine in position. In this way and with a good light a troublesome child's tonsils take very little over the ordinary time of eight seconds for removal.

I am, Sir, yours faithfully,
W. Pugin Thornton.
Devonshire-street, Portland-place, Jan. 14th, 1881.

THE FELLOWSHIP OF THE EDINBURGH COLLEGE OF SURGEONS.

To the Editor of The Lancet.

Sir,—It is time that public attention was drawn to the disgraceful traffic going on in this sham qualification. Time was when it was given to a few, and conferred at least a social distinction in Scotland, and when the income of the college was but slightly enhanced by it. Now I am told they draw about £2000 a year from this source alone. This town and district are being flooded by the bogus distinction, and its holders sign themselves "F.R.C.S." or "F.R.C.S.E.," thus leaving it to be inferred that they are Fellows of the London College. It is getting as bad as the "L.R.C.P." of 1859, and can be stopped in the same way, by an expression of professional opinion.

I am, Sir, yours truly,
Birmingham, Jan. 15th, 1881. F.R.C.S. Eng. (exam).

To the Editor of The Lancet.

Sir,—I fear the statements respecting the regulations in force at the Royal College of Surgeons of Edinburgh alluded to by your correspondent, a "Disinterested Medical Reformer," in The Lancet of the 15th inst., are substantially correct.

The present regulations of the College as regards its Fellowship are a great injustice to the interests of the profession, to its own acknowledged respectability, and to those of its Fellows who have, like myself, many years since obtained the diploma by regular examination. I trust the Royal College will see reason to make such alterations in its rules as will restore its prestige.

Believe me, Sir, yours faithfully,
A Fellow by Examination of
Jan. 17th, 1881. 25 Years' Standing.

Preliminary Examinations of the Royal College of Surgeons.—The Council of the Royal College of Surgeons has just given notice that from and after the 31st of December next these examinations for the diploma of Fellow and Member of the College, at present conducted by the College of Preceptors, under the authority of the College, will cease, and that from and after the date of this notice candidates for the diploma of Fellow will not be required to undergo any preliminary examination beyond that required for the diploma of Member of the College.

GLASGOW.

(*From our own Correspondent.*)

Govanhill, a burgh on the outskirts of Glasgow, has at length secured the services of a medical officer. His duties are that "he should consult with the magistrates and officers of the burgh in all matters requiring a medical opinion, make examinations, submit reports, and attend courts when required, at a salary of *twelve pounds* per annum, the engagement to be terminable on a month's notice on either side." Well might one of the Commissioners present make the remark that he "could scarcely think that any medical gentleman would be willing to accept such an amount of work at such remuneration." The circumstances under which Dr. A. J. Hall, the previous holder of this office, surrendered his appointment are sufficiently remarkable, and should be known to every health officer in the country. Dr. Hall worked for three years as "medical officer of the burgh of Govanhill," imagining that his appointment was under the Public Health Act, a view in which he was supported by the fact that the authorities, in their annual returns, represented his salary as paid under that Act. In the course of last summer, however, he was asked to examine and report in a case of assault; this he did, and charged a small fee. The Commissioners agreed to pay this fee, but intimated that in future no such extra charges would be allowed. The Board of Supervision decided, after some correspondence had passed, that the differences of opinion to which these circumstances had given rise could be settled only in a court of law. The burgh of Govanhill thus appears before the professional public in a very discreditable light; they ask an officer, whom they employ in their capacity of local authority, to perform the duties not only of medical officer under the Public Health Act, but also of police-surgeon, the Police Act being one of a separate nature, and one for which a special tax is levied. They do this with their eyes open, as witness the statement made by their clerk at a recent meeting. Mr. Robertson Sair, in reference to the proposal that, in advertising for a new officer they should specify his duties, said "that it was dangerous to enter into particulars. Their last engagement was drawn in such an indefinite way that they could scarcely conceive any duty which it would not cover."

IRELAND.

(*From our own Correspondent.*)

The outbreak of fever in Tandragee, county Armagh, to which you alluded last week, has attracted considerable attention, and as I have received reliable information on the subject, a few remarks may not be out of place. The epidemic, it appears, broke out on the 10th December last, and since then 120 cases have occurred; the cause of the outbreak being the contamination of one of the water supplies of the town with dejections from a typhoid patient who was first seen by the medical officer of the district three days after the outbreak in an almost convalescent state. The excretions of this patient were thrown into a small river which at flood-time communicates with the water-supply above referred to, and in this way the disease was spread. Dr. James Taylor, the medical officer of the district, had the water-supply cut off on the 13th December, and only three fresh cases occurred during the week ending the 13th instant. The number of cases which took place since the epidemic broke out, as relieved by the dispensary, is as follows: First week (10th to 17th December), 22 cases; second week, 38; third week, 31; fourth week, 26; fifth week, 3. Thirteen deaths had taken place up to the 13th inst., and not seven, as mentioned by Mr. Forster, Chief Secretary for Ireland, in reply to Mr. E. D. Gray's question in the House of Commons last week.

The Registrar-General for Ireland has made two changes regarding the areas adopted in his returns for the Dublin Registration District. The area has now been extended so as to embrace the registrars' districts of Clontarf and Howth No. 1, Coolock and Drumcondra No. 1, and portions of the districts of Finglas and Glasnevin and Palmerston. The other change relates to the provincial town districts, for which statistics are given, and consists in the substitution of the "Urban sanitary district" for the "Registrar's district," or group of Registrars' districts. These changes have been made with the view of supplying more accurate information regarding the mortality in towns; and, I may add, with the hope of reducing the city death-rate by including in the Dublin Registration District outlying regions whose inhabitants possess a higher standard of health.

Dr. Cameron, President of the Metropolitan Officers of Health Society, at a meeting held at the Royal College of Surgeons last week, delivered the annual address. He stated that the death-rate of Dublin, which during the decade ended in 1877 was 26·2 per 1000 persons living, rose in 1878 to 29·5, and in 1879 to 34·6 per 1000, and continued at the latter high rate in 1880. It was difficult to account for the marked increase in 1879–80, unless it was the result of the destitution which existed in the city during these years, caused by the bad harvest, which reacted upon the town population. The increase in the registered deaths in 1879–80 was to the extent of about 10 per cent., accounted for by the fact, that in these years the registration was corrected by means of returns from the cemeteries, for before 1878 it was found that, owing to defective registration, the burials exceeded the registered deaths by 11 per cent. Making every allowance, however, the increase of registered deaths was in 1879 15 per cent. over the average of the ten previous years. The increase was not due to the greater prevalence of zymotic diseases, compared with the other classes of maladies, all kinds of disease showing an increase. The causes of the high death rate may be attributed to the bad tenement dwellings, the existence of slaughter-houses and dairy-yards in crowded localities, the prevalence of much poverty and intemperance amongst certain classes, and the relatively larger proportion of the poorer classes which distinguish Dublin from English towns. The condition of the tenemental dwellings was very bad, but an improvement in them is being effected, there having been 604 houses unfit for habitation and 197 cellar dwellings detenanted and closed between August 1st, 1879, and Dec. 31st, 1880.

Dr. J. W. Busteed of Tralee has been placed on the Commission of the Peace for the County Kerry.

The annual general meeting of the Dublin Branch of the British Medical Association will be held at the College of Physicians in Ireland on the 27th inst., when the President, Dr. Robert McDonnell, F.R.S., will deliver an address.

PARIS.

(*From our own Correspondent.*)

A MOST promising young physician, Dr. André Poulin, met with his death last week under very painful circumstances. The *concierge* of the house in which he resided had received notice from the landlord to quit, and suspecting Dr. Poulin of having been instrumental in obtaining his dismissal, he determined to have revenge. The delay which had been granted to him to obtain another situation would have expired on the 15th of January, but two days before he put his long premeditated project into effect. Concealed in a bedroom which has a small window commanding the principal staircase, the murderer quietly sighted his victim as he was leaving his apartment at ten o'clock in the evening, in company with several guests, and discharged the contents of one barrel of his gun, wounding him mortally in the groin. The contents of the second barrel were distributed amongst those who had come to the rescue. Dr. Poulin had only recently completed his medical studies and obtained his degree. He had been house-physician for four years at the Paris hospitals, terminating as prize medalist a brilliant curriculum. He was a member of the Anatomical and Clinical Societies, and had been named a short time since to the important post—the first step to the Professorate—of *chef de clinique*, under Professor Hardy.

The death returns of Paris show a great increase of mortality for the last week, which is mainly due to typhoid fever, of which ninety-five cases terminated fatally. This is very nearly four times as much as the average of the corresponding weeks of the last four years (twenty-two), and half as many again as during the preceding week (sixty-three). Pulmonary diseases of all kinds also gave an increased mortality, which brings up the total to 1185, a figure which represents an annual death-rate per 1000 of 30·1.

M. Landrieux, of the Hôpital St. Louis, made a communication to the Société Médicale des Hôpitaux concerning five Esquimaux whom he had recently occasion to treat for small-pox. Of these two died before the period of eruption with hæmaturia, two more died after the exanthem, which was confluent and hæmorrhagic, had appeared. Neither of the patients had been vaccinated. On post-mortem examination the livers and mesenteric ganglia were found to be much hypertrophied, a condition which depended upon the fatty nature of the food used during life.

A discussion has been carried on at the same Society on the Effects of Ear-piercing in Scrofulous Subjects. From a large number of cases quoted by different speakers, it would appear that this trifling operation, usually performed by the jewellers, is often followed by disagreeable consequences. In a strumous person it very frequently sets up ulceration, which persists as long as the earring is worn, and ends by a fissure of the lobule. At other times a troublesome eczema is produced, which cannot always be cured by the removal of the exciting cause.

Dr. Seure has published a memoir which was presented some six months ago to the Academy of Medicine, on the Electric Properties of Dried Collodion. He finds that thin leaves of this substance, which may be detached from glass or metal plates, are negatively electric in the very highest degree, sulphide of copper and gutta-percha being positive in respect to them. In the dark they become luminous by friction, and when rubbed with the fingers they give rise to a sensation of numbness. If the outside of a bottle be covered with collodion, and then rubbed, small sparks can easily be obtained. Dr. Seure thinks that some therapeutic effects may be obtained from this substance. He suggests that leaves of dried collodion should be sewn on the inside of the garments worn by hemianæsthetic subjects, or that they should wear under-sleeves or leggings of collodionised silk. Hemianæsthesia is such a refuge for destitute therapeutic methods that it would be almost a pity to commence operations there. If collodiono-therapy is really an efficient means of applying static electricity, there are other conditions in which it might be tried. Its "æsthesiogenic" power can always be fallen back upon as a last resource.

An ingenious philanthropist proposes to diminish the mortality amongst the wounded in war by tattooing on the soldiers' bodies the principal points where compression may be made in cases of hæmorrhage. Life may be lost in a few minutes by a wound of a large artery, and it is thought that the soldier might often escape if he knew where to command an artery whilst waiting for help.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, 13th inst., a petition was presented from Thomas Robinson for inquiry into the East India Medical Service. The Medical Appointments Qualifications Bill, brought in by Mr. Errington and Mr. A. Moore, was put down for second reading on the 20th.

On Friday, upon the motion of Mr. Secretary Childers, the select committee on the Contagious Diseases Acts was appointed in the following terms:—"To inquire into the Contagious Diseases Acts, 1866–1869, their administration, operation, and effect:" Mr. Massey, Mr. Stansfeld, Mr. Cavendish Bentinck, Colonel Alexander, Viscount Crichton, Mr. Burt, Mr. O'Shaughnessy, Mr. Osborne Morgan, Mr. Cobbold, General Burnaby, Sir Henry Wolff, Mr. Ernest Noel, Colonel Digby, Mr. William Fowler, and Mr. Hopwood. Power to send for persons, papers, and records; five to be the quorum. Ordered, that all reports and returns relating thereto be referred to the said committee; that it be an instruction to the committee that they have power to receive evidence which may be tendered concerning similar systems in British Colonies or in other countries, and to report whether the said Contagious Diseases Acts should be maintained, amended, or repealed. A Government Bill to revise the constitution of endowed schools and hospitals in Scotland was brought in by Mr. Mundella.

On Monday, in reply to Mr. H. B. Sheridan, Mr. Courtney (the new Under-Secretary for the Home Department) stated that it was not intended to recommend the remission of any portion of the sentence passed upon the chemist Titley. Further petitions for inquiry into the Medical Service of the Indian Army were presented from Thomas Beaumont and George Burn. According to the order-book of the House of Commons, as printed on the above day, the second reading of the Medical Appointments Qualification Bill is fixed for the following Thursday; the Endowed Schools and Hospitals (Scotland) Bill stands for second reading on the 27th instant; the Medical Act 1858 (Amendment) Bill is the first order for Wednesday, February 2; Mr. P. A. Taylor's anti-vaccination motion has the first place for Tuesday, Feb. 8; the Infectious Diseases Notification (Ireland) Bill stands for Wednesday, March 30th; Mr. Dillwyn's Lunacy Law Amendment Bill is put down for Wednesday, May 25th; and the Contagious Diseases Acts Repeal Bill is fixed for second reading on June 15th. The following is the text of Mr. Cubitt's notice for which no day has yet been fixed with regard to London fogs:—"To move for the appointment of a Select Committee to consider to what extent the fogs of London are injurious to life, health, and property; whether they have increased and are increasing from causes which are controllable; whether the existing Acts of Parliament relative to the consumption of smoke are applicable to the present state of the metropolis, and can still be enforced; and whether alteration and extension of this legislation would be beneficial."

On Tuesday, the Government withdrew their Endowed Schools and Hospitals (Scotland) Bill, and a fresh Bill was introduced, "To Reorganise the Educational Endowments of Scotland." The second reading of the River Floods Prevention Bill was deferred to Tuesday next. Mr. Healy gave notice that he would ask leave to introduce a Bill to amend the law relating to coroners in Ireland. Mr. Moore gave notice of a question as to the production of the evidence taken at a recent inquiry by Inspectors Bourke and Brodie at Belfast Workhouse.

On Wednesday, a petition was received from C. E. Raddock for inquiry into his case. A Bill for the Appointment of a commission on local boundaries was brought in by Lord E. Fitzmaurice. Mr. Sexton gave notice that he would move for particulars of a recent inquiry at Dromore Workhouse.

On Thursday, Mr. Warton asked the Secretary of State for the Home Department whether it was the fact that, acting under the advice of the Lunacy Commissioners, such advice being supported by the report of a medical superintendent of asylums, he declined to sanction the enlargement of the Joint Counties Asylum at Abergavenny; whether he did not subsequently reconsider his decision, being influenced so to do by the advice of Dr. Gover, the Medical Inspector of Prisons; and, whether the recommendation of the Lunacy Commissioners was set aside in consequence of the opinion of a medical man unconnected with their body. Sir W. V. Harcourt said the facts were these: The Committee of Visitors wanted to enlarge the asylum. The Commissioners in Lunacy thought there ought to be a new building on a new site. It was left to the Secretary of State to settle the point; and when he (Sir William) came into office he carefully investigated the matter. It was finally reported to him that, although a new building on a new site would be ideally the most perfect thing, still an additional building on the old site would do well enough; and the consequence was that he declined to force the local people to go to an unnecessary expense. He desired to add that, with the present heavy burden of the rates, he did not wish to use the central authority to compel the local authorities to enter into expenditure which they felt to be unnecessary, and which could not be proved to be necessary. Mr. Errington asked the Vice-president of the Council whether he would agree to the appointment of a Select Committee to continue the inquiry commenced in 1878 into important questions of medical reform. Mr. Mundella stated that last year there was a Medical Bill of the Government before the House. It was referred, with other Bills, to a Select Committee. The Government did not see any probability of a Medical Bill being discussed and receiving proper attention this session, and they therefore had no intention of introducing such a Bill. But they thought it probable that some advantage would result from a continuation of the inquiry. The whole question was under consideration, and he would confer with his hon. friend about it.

Obituary.

WILLIAM ALEXANDER WHITE, M.D.

THE death of Dr. W. A. White, late of the Army Medical Service, is announced as having occurred at Duncan-street, Edinburgh, on the 29th ult. Dr. White, who was a graduate of Edinburgh, obtained his commission as an Assistant Surgeon on the 18th October, 1853, and was shortly afterwards gazetted to the 47th Regiment, with which corps he served in the Mediterranean and throughout the Crimean Campaign, including the battles of Alma, Balaclava, Inkerman, and the Fall of Sebastopol (medal and three clasps and Turkish medal). He was promoted staff-surgeon in May, 1863, and was appointed to the Royal Artillery in January, 1864, serving in charge of a brigade in India for several years. He became Senior Surgeon-Major in 1873, and did duty in Dublin prior to his retirement in October, 1879, on half-pay, when he was granted the honorary rank of deputy surgeon-general. Dr. White was unmarried.

SURGEON-MAJOR WILLIAM IRONSIDE.

WE regret to announce the death on the 16th instant, in Edinburgh, of Surgeon-Major William Ironside, M.D., of the Army Medical Department. Dr. Ironside studied at Aberdeen, of which University he was a graduate, and entered the Army as an Assistant-Surgeon on the 1st April, 1861. He was shortly afterwards gazetted to the 71st Highland Light Infantry, with which regiment he served several years in India, being transferred to the Royal Artillery on the reduction of the junior assistant-surgeons of regiments in India. He was promoted Surgeon-Major in April, 1876, returned from a tour of service in India in 1878, and had been stationed in Edinburgh for the last two years. He leaves a widow and two children to mourn his loss.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 18th inst.:—

Carter, D'Arcy Bainbridge, Leeds.
Clarke, Walter James, Birmingham.
Evans, Thomas Jones, Llanybyther, Carmarthen.
Holt, William, Camberwell New-road.
Hooley, Arthur, L.R.C.P. Edin., Cobham.
Houghton, F. E. Caulfield, Dudley.
Jones, Robert Langford, L.S.A., Bangor.
Loynd, William, Gt. Harwood.
Matthews, Samuel Richard, Llandinabo.
Oates, John Harrison, Dewsbury.
Poett, Patrick Matthias, L.K. & Q.C.P. Irel., Teremire, Dublin.
Prendergast, Joseph Moran, L.S.A., Melbourne, Australia.
Sellers, William, M.D., Radcliffe, Manchester.
Sharples, William Henry, Preston.
Stanwell, William, Rochdale.

The following gentlemen were admitted Members on Wednesday last:—

Bell, William Taylor, Totteridge Park.
Bond, Richard Pratt, L.R.C.P. Edin., Cheltenham.
Brown Percy, L.S.A., Camberwell.
Chronnell, James, Manchester.
Field, C. A. E. Adolphus, Camden-road.
Gardner, James Clark, Newcastle-on-Tyne.
Lidiard, Sydney Robert, Dulwich-road.
Marshall, James, Plymouth.
Puddicombe, Francis Morgan, Dartmouth.
Roberts, Frank Ernest, Lower Norwood.
Shepherd, T. A. Jordan, L.S.A., Rotherhithe.
Voision, Alexander Bishop, Jersey.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Jan. 13th:—

Conway, Thos. Henry, New Burwell, Newcastle-on-Tyne.
Sumner, Joseph Henry Sturtees, Redburn-street, Chelsea.

THE salary of Mr. Ilott, medical officer of the Whitechapel Union Infirmary, has been increased from £200 to £250 per annum; and that of Dr. Knox, senior resident medical officer of St. Matthew Workhouse, Bethnal-green, from £200 to £250. The West Ham Board of Guardians have raised the salary of Dr. Scoresby-Jackson, Medical Officer for Walthamstow, to £150 per annum.

MANCHESTER MEDICAL SOCIETY.—At the annual meeting of the Society held at the Owens College on Jan. 12th, the following office-bearers and members of committee were elected for 1881:—President: Mr. Edward Lund. Vice-Presidents: Mr. John Broadbent, Dr. James Hardie, Dr. George Stevenson, and Mr. Walter Whitehead. Treasurer: Mr. F. A. Heath. Secretary: Mr. Chas. Jas. Cullingworth. Honorary Librarian: Mr. Thomas Windsor. Other Members of the Committee: Drs. Henry Ashby, Julius Dreschfeld, Arthur Gamgee, Charles Edward Glascott, Robert Hopwood (Stalybridge), Thomas Jones, John Dixon Mann, Henry Colley March (Rochdale), Siegmund Moritz, Joseph Chadwick Peatson, Edwin Rayner (Stockport), and William Yeats. (The above, with the past presidents of the Society and two representatives from the council of Owens College, form the committee.) Auditors: Drs. Abraham Matthewson Edge and Alexander Hodgkinson. Editor of the Society's proceedings: Dr. Charles Edward Glascott. The report stated that the number of members now on the roll is 219, as compared with 208 last year. 1357 volumes have been added during the past year to the library, which now numbers (excluding duplicates) 25,252 volumes.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting on Tuesday, Jan. 11th, the following list of officers and council was adopted, the newly elected being those proposed by the council for ballot:—President: Mr. Reginald Harrison. Vice-Presidents: Dr. Caton, Dr. Dickinson, Dr. Gee (newly elected), and Mr. Townson (newly elected). Hon. Treasurer: Dr. W. M. Campbell. Hon. General Secretary: Mr. Rushton Parker. Hon. Secretary, Ordinary Meetings: Mr. E. A. Browne. Hon. Librarian: Dr. Howie. Council: Dr. Barr, Mr. Banks, Mr. McCheane, Mr. Ransford, Dr. Rawdon, Dr. Waters, Dr. Burton (newly elected), Dr. Costine (newly elected), Dr. Cregeen (newly elected), Dr. Hicks (newly elected), Dr. Hoppey (newly elected), and Mr. Paul (newly elected). Microscopical Committee: Dr. Alexander, Dr. Braidwood, Dr. Briggs (newly elected), Dr. Glynn, Dr. Grossmann (newly elected), Dr. Hicks, Mr. Newton, Mr. Rushton Parker, Mr. Paul, and Dr. W. Williams (newly elected).

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly court of the Directors of the above Society was held on Wednesday, Jan. 12th, at 5 P.M. Mr. John Gregory Forbes, V. P., in the chair. A sum of £1270 was awarded to fifty-nine widows, fifteen orphans, and three recipients of relief from the Copeland Fund. The expenses of the quarter were £63 2*s.* 6*d.* There were no fresh applicants for ordinary grants, and one only for extra relief from the Copeland Fund. Two new members were elected and the death of one was announced.

MR. J. WHITE HOPKINS, of the Swinnerton District of the Stone Union, has received a first-class grant for successful vaccination.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

CASSON, H., M.R.C.S.E., has been appointed Medical Officer to the Stapleford District of the Wilton Union, vice Straton, deceased.

CUNNINGHAM, A., M.B., C.M., has been appointed Medical Officer of Health for the Oldbury Urban Sanitary District.

FARRAR, C., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer to the Fourth District of the North Witchford Union.

FURNIVALL, C. H., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of Health for the District of Acton.

HOOPER, A., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer of the Burton-on-Trent District and Workhouse of the Burton-on-Trent Union.

KAY, T. V., L.R.C.P.Ed., L.R.C.S.Ed., L.F.P.S.G., L.S.A.L., has been appointed Medical Officer and Public Vaccinator to the Clay Cross District of the Chesterfield Union, vice Wilson, deceased.

MILLES, W. J., L.R.C.P.L., M.R.C.S.E., has been appointed House-Surgeon to the Royal London Ophthalmic Hospital, Moorfields.

OGILVIE, L., M.B., B.Sc., has been appointed Extra Physician to the North West London Free Dispensary for Sick Children.

WILLIAMS, DAWSON, M.B., M.R.C.S.E., has been appointed Medical and Surgical Registrar to the Victoria Hospital for Children, vice Beckingsale, resigned. [In our last issue the Christian and surname were accidentally transposed.]

Births, Marriages, and Deaths.

BIRTHS.

ELLISON.—On the 13th inst., at Blythe House, Forest-hill, the wife of Frederick W. Ellison, M.R.C.S.E., of a son.

SHELDON.—On the 14th inst., at Cornwall-road, Notting-hill, the wife of Thomas Sheldon, M.D., of a son.

TICEHURST.—On the 8th inst., at Silchester House, St. Leonard's-on-Sea, the wife of A. R. Ticehurst, M.R.C.S.E. &c., of a son.

MARRIAGES.

DANIELL—KIRKMANN.—On the 19th inst., at St. Mark's, Kennington, by the Rev. W. Griffiths, M.A., Herbert E. Daniell, M.B., eldest son of the late Alfred Daniell, Esq., Surgeon, to Edith, youngest daughter of the late W. Kirkmann, Esq.

HOBSON—WATTS.—On the 13th inst., at St. John's Church, Broughton, Manchester, John Morrison Hobson, M.D., of Addiscombe Villas, Lower Addiscombe-road, Croydon (son of the late Dr. Benj. Hobson, of China), to Emily Ashton, eldest daughter of Joseph Watts, Esq., of Lower Broughton, Manchester.

DEATHS.

COOPER.—On the 8th inst., at South-hill-park, Hampstead, Thomas Henry Cooper, M.R.C.S.E., eldest son of Thomas Cooper, Esq., late of Well-walk, Hampstead, aged 33.

CRUCKNELL.—On the 14th inst., at Epsom, after a long illness, H. H. Crucknell, M.D., Fellow of Oriel, Oxford, aged 50.

GIBSON.—On the 29th ult., at Auteuil, Paris, Isa, second daughter of William Gibson, M.D., of Campbeltown, Argyll, aged 18. Friends are requested to accept this, the only intimation.

IRONSIDE.—On the 16th inst., at Edinburgh, Surgeon-Major William Ironside, M.D., Army Medical Department.

KERR.—On the 19th inst., suddenly, William Kerr, L.R.C.P.Ed., L.F.P.S.G., of 50, Vauxhall-walk, Lambeth, S.E., aged 37. Deeply regretted.

MOORE.—On the 17th inst., at his residence, 3, Queen-street, Lancaster, J. Daniel Moore, M.D., after a lingering illness, aged 46.

TIMS.—On the 8th inst., at North-street, Langport, Thomas Lamb Tims, L.R.C.P.Ed., M.R.C.S.E., L.S.A.L. Relatives and friends will kindly accept this intimation.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

INTERNATIONAL MEDICAL CONGRESS.

LONDON, AUGUST 2ND TO 9TH, 1881.

SECTION IV.—MEDICINE.

Sir WILLIAM WITHEY GULL, Bart., D.C.L., LL.D., F.R.S., President.

Professor W. T. GAIRDNER,
Dr. GEORGE JOHNSON, F.R.S.,
Dr. RICHARD QUAIN, F.R.S.,
Dr. WILLIAM ROBERTS, F.R.S.,
} Vice-Presidents.

Dr. DYCE DUCKWORTH,
Dr. WILLIAM M. ORD,
} Secretaries.

Proposed List of Subjects for Discussion.

1. Localisation of Disease in Brain and Spinal Cord, so far as pathognomonic and diagnostic.
2. Trophic changes of Nerve-origin.
3. Vascular changes, functional and organic, in Disease.
4. Primary diseases of the Lymph-system.
5. Gout, Rheumatoid Arthritis, and Rheumatism.
6. Forms of Renal Diseases (Bright's Diseases).
7. Methods of Physical Diagnosis.
8. Therapeutic Methods:—Revulsions, Blood-letting, Diet-cure, Uses of Heat and Cold, Drug-cure, &c.

All communications regarding Section IV. should be addressed to Dr. ORD, 7, Brook-street, Grosvenor-square, London, W.

SECTION I.—ANATOMY.

Prof. FLOWER, LL.D., F.R.S., President.

Prof. MACALISTER, M.D.,
Prof. ROLLESTON, M.D., F.R.S.,
Prof. TURNER, M.B., F.R.S.,
} Vice-Presidents.

Prof. CURNOW, M.D.,
Prof. THANE,
} Secretaries.

This Section will receive communications relating to any of the following subjects:—1. Human Anatomy, descriptive, microscropic, and topographical; 2. Embryology and Teratology; 3. Anatomical Anthropology and Anthropometry; 4. Comparative Anatomy in so far as it illustrates structural arrangements in Man; 5. Improved Methods of Instruction in Anatomy, and of preparing and preserving Anatomical Specimens.

Medical Diary for the ensuing Week.

Monday, Jan. 24.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ A.M. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 P.M.

Royal Orthopædic Hospital.—Operations, 2 P.M.

St. Mark's Hospital.—Operations, 2 P.M. ; on Tuesday, 9 A.M.

Medical Society of London.—8½ P.M. Second Lettsomian Lecture: Sir Joseph Fayrer "On Tropical Dysentery and Diarrhœa."

Tuesday, Jan. 25.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 P.M.

West London Hospital.—Operations, 3 P.M.

Royal Institution.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

Royal Medical and Chirurgical Society.—8.30 P.M. Dr. Ransome, "On Further Observations on the Value of Stethometry in the Prognosis of Chest Disease."

Wednesday, Jan. 26.

National Orthopædic Hospital.—Operations, 10 A.M.

Middlesex Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ P.M., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ P.M.

King's College Hospital. — Operations, 2 P.M., and on Saturday at 1 P.M.

London Hospital.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 P.M.

University College Hospital. — Operations, 2 P.M., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children. — Operations, 2½ P.M.

Association of Surgeons practising Dental Surgery. — 8½ P.M. Annual General Meeting.—Mr. W. A. N. Cattlin, "On the Imperfections of the Dentists Act, with suggestions as to the Alterations required to protect the interests of qualified Surgeons."

Hunterian Society.—8 P.M. Mr. Waren Tay, "On a case of Colotomy."—Mr. Gilbert, "Notes on Cases in General Practice."

Society for the Encouragement of Arts, Manufactures, and Commerce.—8 P.M. Mr. Edmund Johnson, "On Five Years' Experience of the Working of the Trade Marks' Registration Act."

Thursday, Jan. 27.

St. George's Hospital.—Operations, 1 P.M.

St. Bartholomew's Hospital.—1½ P.M. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 P.M.

Central London Ophthalmic Hospital. — Operations, 2 P.M., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 P.M.

North-West London Hospital.—Operations, 2½ P.M.

Royal Institution.—3 P.M. Mr. Francis Hueffer, "On the Troubadours."

Friday, Jan. 28.

St. George's Hospital.—Ophthalmic Operations, 1½ P.M.

St. Thomas's Hospital.—Ophthalmic Operations, 2 P.M.

Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

Royal Institution.—9 P.M. Dr. Schuster, "On Modern Spectroscopy."

Quekett Microscopical Club.—8 P.M. Mr. B. W. Priest, "On Sponges."—Dr. T. S. Cobbold, "On Filariæ."

Clinical Society of London.—8½ P.M. Dr. Sutherland, "On a Case of Chronic Vomiting, in which no food except Koumiss was taken for sixteen months." –Mr. Hulke, "On the Results of a Trial of Chian Turpentine as a reputed Remedy for Cancer of the Female Genital Organs, conducted during several months of 1880 in Whitbread Ward, Middlesex Hospital."—Mr. J. W. Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Theology and Medicine.

The *Echo* gives currency to the following singular statement:—"The parish priest of Sendomi, in the diocese of Lerida, Spain, has declared from the pulpit that the last absolution, extreme unction, and Christian burial will henceforward be refused to any parishioner who allows himself, or whose kindred allow him, to be treated by any but duly qualified medical practitioners. All men, women, or children who are treated homœopathically will be deprived of the rites of the Roman Catholic Church, and treated as Moors or Jews."

SEWERS AND MILK.—DIPHTHERIA.

To the Editor of The Lancet.

Sir,—In the last number of The Lancet it is stated that the recent outbreak of diphtheria at Surbiton may be attributed to "foul water" from a well "occasionally used," which, it is inferred, "was reserved for dairy purposes." When first called in I warned the dairymen against using the well-water, and he assured me that it was never used "for dairy purposes." In the scullery, close to the door of the dairy, I observed a large sized earthenware pipe in direct communication with the soil drains running into the main sewer, which had been overlooked by the sanitary officials, and from this drain-pipe the deceased girl complained of having "swallowed the smell," of which she sickened immediately afterwards.

I am informed now that another dairy is supposed to be spreading this disease. How is it that the diphtheria should be confined to Surbiton, while the dairymen are supplying all the surrounding neighbourhood, including the Metropolitan Convalescent Institution for Children, without infecting any of them?

I have attended many cases, in all of which I can prove that the disease originated from the drains, and not from the milk, which was supplied from a variety of dairies, added to which I have treated every case as arising from drains, and none of the casualties have been amongst my patients, for the death in the dairyman's house was not from diphtheria.

There is only one ventilator in the drains throughout the populous part of Surbiton, and these drains are at times poisonous. Their condition was thus described by a resident on the 24th December last:—"I had three servants ill with gastric fever. I called in the inspector of nuisances, and he at once saw that I was ventilating the entire neighbourhood, and advised that a trap should be placed at my junction with the main sewer. I shall never forget the rush of foul air that took place when the junction was broken. The workman was driven backwards, and his candle put out, and I was made quite sick by the stench." This gentleman disconnected the sewer from his own house, and as there was no extra ventilator provided, the neighbours are the sufferers.

It is evident that with the drains of Surbiton in the condition above described—charged with "stench"—we cannot hope to escape diphtheria and other contagious diseases at certain periods; and it appears an absurdity to me to ascribe the existing sickness to milk. I have suggested that the Government sanitary engineer should be consulted as to the propriety of introducing ventilators into the drains, but the local authorities do not appear willing to adopt this measure. Some years ago ventilators were introduced into the drains of Kingston at my suggestion, with satisfactory results.

It would be interesting to know the opinion of the profession as to the necessity of burning the bedding and stripping the paper from the walls of a house where there has been a case of diphtheria.

I am, Sir, your obedient servant,
Robt. Collum, M.D.
Sutherland House, Surbiton, Surrey,
Jan. 5th, 1881.

"THE CUP" AT THE LYCEUM.

MR. IRVING as Synorix in this tragedy, after having swallowed the fatal draught at the hands of Camma, and feeling death approaching, says:—

> "I pray you lift me,
> And make me walk awhile, I have heard
> These poisons may be *walked down*: my feet
> Are tons of lead."

He is then partially raised by one of his retinue, but dies apparently in convulsions, with marked opisthotonos; on the contrary, Miss Ellen Terry as Camma, who has also swallowed the same draught, but less of it, lives long enough to see Synorix die, and then expires herself *quietly* in the arms of one of her handmaidens. The phrases "I have heard these poisons may be walked down" and "My feet are tons of lead" are certainly indicative of opium poisoning, but why the death convulsions? and why the difference in the mode of death in the two victims?

INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—The leading article in your issue of October 2nd, 1880, on the above subject, while it draws attention to its genuineness as a service, does not sufficiently note the harm which will come of the recent orders in a professional point of view—that aspect which it most concerns a purely medical journal to keep an eye upon. Nay, it even intensifies one of the mistakes. There has been no complaint, so far as I am aware, that sanitary commissioners are not fully recognised, but rather the reverse. By the recent orders, whereby the prizes of the service are given to sanitary officers, it is lamentably clear that high professional qualifications are at a discount. Those very qualifications for which we are educated, selected, and imported into India at great expense to ourselves and to the State, and which it "pays" the State to secure and to utilise, are apparently not held in such high estimation or deemed so worthy of reward as a vague general knowledge of what is good for health. If a sanitary commissioner is to be promoted to the rank o deputy surgeon-general after twenty-six years' service, it seems strange to withhold it from the principals and professors in the presidency colleges of the same standing, or in fact from any man of acknowledged ability and professional skill.

Far be it from me to undervalue sanitary science, but sanitary science as required in India cannot for a moment be compared in value or in scale with good professional knowledge and practical skill. It is in a most elementary state. A man need not have much medical knowledge or any special education at all to be a sanitary officer in India. Before now sanitary commissioners have been "laymen," and though perhaps such a thing may not occur again, yet sanitary commissioners cannot even now lay claim to any high special knowledge. They are liable to be contradicted, or differed from, or involved in an argument with any omniscient administrator who "fancies" himself in sanitary matters, and the professional man does not always get the best of it, as witness many points during the late famine.

And even now, after the dismal experiences of that time, so little is medical opinion regarded in State affairs or scientific sanitarianism, that the late Famine Commission, which has been roaming about and deliberating in various parts of the empire, at an enormous expense, the prime object of whose cogitations was the saving of human life, was composed entirely of "laymen." The results of their labours have just been given to the world, and for this very reason, however important they may be generally, are in great part shorn of their worth and value.

But Government in India is eminently unscientific and rather see-saw, and this is a notable instance of it. At one time the amount of medical knowledge in a sanitary commissioner is thought so little of that a layman is appointed to the office; at another it appears to be so much appreciated that not only is he to be a medical man, but he is to be held worthy of high reward among his own brethren. And here it is, I think, that medical journals should point out the mistake that is being made, and should not fail to insist that if honours are to be given to medical men, it should be primarily for high professional ability, and not for such qualifications as an Indian sanitary officer need have.

Hitherto the Indian Medical Service has not been wanting in skilful and well-accomplished men, but it is inevitable that professional knowledge would decline where it was not properly recognised and rewarded. At all events, men who possess it in high degree, and who are distinguished in the practice of their profession, should not be liable to departmental supersession.

I am, Sir, yours, &c.,

India, Oct. 28th, 1880. SURGEON-MAJOR, I.M.D.

The Littlehampton Provident Dispensary.—We have frequently expressed our disapproval of dispensaries conducted by one medical officer at very low fees.

Dr. Rae's paper is marked for insertion.

A Young Practitioner.—The case is probably a neurotic one. Morphia, chloral, and all such remedies are to be shunned as likely ultimately to make matters worse. Tonics, change of air and circumstances, and the expression of a hope that with advancing years pain will be less, are the principal measures to be recommended.

M.R.C.S.—We think our correspondent is right on both points. To absolutely refuse consultation with a qualified practitioner would be doubtful ethics, and would certainly be bad policy. It would excite a charge of "trades unionism," &c. Consultations should be taken only on dignified terms. The scheme adopted is a bad one, and has frequently had our disapproval. Working men and their wives are not likely to be long satisfied with a doctor chosen by others and on terms unremunerative to the surgeon appointed and disrespectful to practitioners of standing in the town.

Mr. Hilles.—It would be better, we think, to postpone the publication of the description until the instrument has been tested.

Mr. C. C. Burman.—Soon.

A Pupil is referred to the article on Books in our Students' Number.

Mr. G. A. Warren should consult his usual medical attendant.

ORCHITIS AS A CONCOMITANT AND SEQUEL OF MEDITERRANEAN FEVER.

To the Editor of THE LANCET.

SIR,—Among the remittent fevers that in almost every part of the globe affect the health of our imperial forces on land and sea there is none probably that cause so high a ratio of invaliding and individual inefficiency as that peculiar type best known under the name of Mediterranean fever. Seldom fatal in its result, but insidious in its approach, it too often leaves its victim a mere wreck of his former self, and when at last, after vainly endeavouring to shake it from him, he seeks a remedy by returning home to breathe his native air, he finds for months his limbs attacked by neuralgic pains, and his movements crippled by rheumatic joints. As it has been often noted that these remittent fevers differ one from another in some respects according to the localities in which they have been contracted, and have many of them a certain individual stamp, so we find in this particular variety to which I am alluding a marked tendency to rheumatic affections of the different organs and tissues of the body.

During the early part of this year I had the honour of serving on board of one of Her Majesty's ironclads in the Mediterranean, and spending some months lying in the harbour of Caletta without moving, had an opportunity of studying a slight outbreak of this fever among her crew.

Invaliding from foreign stations naturally removes from under the eye of the medical officer many of his worst cases, and their sequel is consequently lost to him, but out of twenty-three cases occurring on board, four suffered from what I believe to be not a common complication, and one which is the subject of this letter—viz., a rheumatic affection of the testis and neighbouring structures. In two of the patients the affection ushered in the disease after a few days' premonitory symptoms, and in the others it followed as a sequel, in one case three months, in the other four, after the acute stage of the fever had passed away, and while they were still labouring under the debility consequent upon the attack. In all of them the body of the testis was the first part affected, the organ rapidly enlarging, and testicular sensation being much impaired after two or three days. Subsequently the inflammation extended to the epididymis, and in one of the cases a hydrocele made its appearance on the same side, and was tapped. The disease was confined to one side. Under appropriate treatment the inflammation, which was very considerable in all of them, resolved, and the infiltration of the testes and epididymitis, which were great, disappeared in a rapid and marvellous manner, leaving the organs intact.

I will not even hazard an opinion on the nature of the *materies morbi* in this fever, which singles out the fibrous tissues of the body for its attacks, producing often excruciating neuralgia by affecting the neurilemma of the nerves, impairment of the joints by affecting their tendinous surroundings, and in a similar manner, is frequently the cause of effusions into the pericardia and pleuræ. Is it analogous to that of ordinary rheumatic fever? This is a question to be solved by those eminent pathologists the results of whose researches in all parts of the world are daily adding fresh knowledge to our craft. I am only a simple recorder of facts, and leave deductions to them.

I am, Sir, yours obediently,

H. M. ELLIS, R.N.

Royal Marine Artillery, Eastney, Dec. 17th, 1880.

Mr. J. S. Grubb.—As the question is put, we should say the guardians have no such power.

F.R.C.S.I. has not enclosed his card.

Mr. Malcolm Morris's lecture will appear in an early number.

THE TERMS OF ATTENDANCE ON ODDFELLOWS.

To the Editor of THE LANCET.

SIR,—I shall be much obliged if any of your readers can tell me of any lodge of Oddfellows which pays its medical officer more than four shillings a year for each member, also if the fee includes attendance in cases caused by intemperance, such as delirium tremens, and how long a distance from the lodge the medical officer is expected to attend. Information upon the above points will greatly oblige.

I am, Sir, yours faithfully,

Ben Regis, Jan. 19th, 1881. F. D. LYS.

STIMULANTS IN WORKHOUSES.

AT a recent meeting of the Prestwich Board of Guardians a discussion arose upon the subject of the consumption of stimulants in the workhouse, and Mr. Basil Cane, Local Government Board inspector, who was present, on being appealed to for his opinion, said he had seen good results follow the supply of drugs by the guardians themselves, because it relieved the medical officer of the inducement to do with wine and spirits—paid for by the union—what he would otherwise have effected with drugs. If the guardians supplied the latter there would probably be a reduction in the bill for stimulants.

"PREMATURE LABOUR INDUCED BY QUININE."

To the Editor of THE LANCET.

SIR,—I see in the number of your journal received last mail a short article on the above subject by Mr. E. Downes, and as lately I have had an exactly similar case, with an opposite result, I think it may be of some interest to record it.

The patient, aged twenty-seven, was seven months' gone in her fourth pregnancy, and was brought to an extremely debilitated and anæmic condition from repeated attacks of ague. Quinine was prescribed, at first in small doses, and subsequently increased to twenty grains per day, and continued for about three weeks. The attacks of fever disappeared under its influence, and she has now arrived almost at her full time, without any uterine disturbance of any sort, while taking the drug.

During a severe epidemic of malarial fever last year in Rangoon I had an opportunity of giving quinine in several like cases, and never saw any attempt even at the induction of labour, though I am aware that it is sometimes reputed to act in this manner.

I remain, Sir, yours faithfully,
H. A. FOGERTY, M.D., Surgeon, A.M.D.

Meerut, India, Nov. 8th, 1880.

To the Editor of THE LANCET.

SIR,—Mr. Downes's letter from Kashmere, published in your issue of the 16th October last, regarding the induction of premature labour by quinine, induces me to mention a case which occurred recently. I was called to see a lady in her eighth month of pregnancy. She had two severe attacks of the tertian type before I saw her. I tried arsenic in full doses, but without benefit. I then gave her three-grain doses of quinine twice a day with Fowler's solution and tincture of opium, but without effect. She had had by this time six attacks, and felt pain in the back, loins, and down the thighs. The last two attacks of fever were very severe, with delirium. I therefore decided to give a fairly large dose of quinine, and accordingly administered ten grains, with ten minims of tincture of opium, at 4 o'clock on the morning of the fever day. It was at once checked without a bad symptom. I repeated the dose in the morning of the next expected attack, and gave three grains, with eight minims of tincture of opium, on the intermediate day, with the best result.

Fever doubtless causes premature labour. I had a case last year in which, without quinine, the membranes burst during fever, but labour did not occur for a week after. The fever was then of eight days' duration (remittent, with insensibility), which on the eleventh day subsided. This patient was confined of a seven months' child, which did not survive its birth more than thirty hours. I have always given quinine, combined with tincture of opium, in all periods of pregnancy, and cannot call to mind any case where it produced abortion or premature labour. I believe that tincture of opium modifies, or entirely checks, any reputed or real ecbolic action of the alkaloid. Arsenic takes time to act, and the delay allows of the fever poison operating in the specific manner now generally admitted.

I am, Sir, yours faithfully,
W. J. LINCOLN, L.R.C.P., &c.,
Mysore, Nov. 17th, 1880. Civil Surgeon.

ON THE ASSOCIATION OF AFFECTIONS OF THE THROAT WITH ACUTE RHEUMATISM.

To the Editor of THE LANCET.

SIR,—I have only just seen the paper of my friend Dr. J. K. Fowler on the above subject in THE LANCET of December 11th, and also the letter of my former colleague, Mr. Lennox Browne, in the issue of the 25th December. I should like to be allowed to bear corroborative testimony as to the apparent connexion, which I have frequently noticed, between rheumatism and certain throat affections, tonsillitis especially. My attention was first drawn to the point by Mr. Lennox Browne, some four years ago, when I was acting as his clinical assistant, and I have observed it in many cases since. In almost all cases of tonsillitis which I have treated since that time I have prescribed salicylate of soda, in combination with sulphate of magnesia, and sulphate or salicylate of iron, usually with very excellent results. Patients who have had tonsillitis several times before have assured me that they had never previously got over an attack so quickly as they did under this treatment. As far as my reading goes, I think Mr. Lennox Browne was the first to note—certainly the first to emphasise—the etiological, semeiological, and therapeutic analogy between tonsillar inflammations and the arthritic diathesis. It is valuable and interesting to have the corroborative independent testimony of such an evidently careful observer as Dr. Fowler.—I am, Sir, yours obediently,

DOUGLAS HEMMING, F.R.C.S. Ed.

Bournemouth, Dec. 31st, 1880.

ABSTRACT OF

The Brown Lectures.

FURTHER INVESTIGATIONS ON ANTHRAX AND ALLIED DISEASES IN MAN AND ANIMALS.

BY PROF. W. S. GREENFIELD, M.D., F.R.C.P.

LECTURE IV.

BEFORE discussing the minute anatomy and the pathology of "woolsorters' disease," Dr. Greenfield gave an account of the cases of anthrax (splenic fever) in the cow and sheep, which had apparently arisen from drinking water in which infected wool or hair had been washed, and showed that these cases were proved by the microscope and by experiments to be really cases of anthrax. Moreover, they were of interest from the fact that the examination of the various fluids from these animals side by side with those from men showed the identity of the conditions in both.

Passing next to the microscopical anatomy of anthrax in the lower animals, he described the various appearances usually met with in splenic fever of cattle and in animals inoculated from them. The multiple ecchymoses found in various organs were shown to be usually due to thrombosis of vessels by masses of bacilli, not uncommonly the artery or vein being filled by a plug consisting entirely of bacilli, and the extravasated blood containing them only in very small numbers. This was especially the case in the heart, lung, and brain, but occurred also in other situations. It might be, however, that the bacilli, especially in the lung, were far more widely distributed, occupying in large numbers the pulmonary capillaries throughout a wide area of the lung. In the lymphatic glands and spleen they might be almost entirely limited to veins and venous sinuses, or more widely diffused. In the kidney the glomeruli, particularly those nearest the surface of the cortex, were their especial site, where they occupied and often filled the glomerular capillaries. He stated, however, that in some cases this general distribution of the bacilli was not observed, but they were almost entirely limited to certain organs, especially the lungs, and in one case to certain vessels supplying some of the bronchi, where they produced special changes.

Turning next to the subject of human anthrax, he described the changes found in the malignant pustule, following the descriptions of Davaine, Thiersch, Wagner, and Colin, and stating that he had had no opportunity of studying them for himself in man. He believed, however, from observations on the lower animals, that whereas in the majority of cases the infection of the general system occurred through the lymphatic glands, it was not at all improbable that the virus might enter the blood-stream locally through the capillaries of the affected part, and that this partly accounted for the great difference in the results of equally severe local affection. The theory of double parasitism of bacilli and micrococci, advocated by Buchner to account for the local phenomena, he did not think supported by the evidence.

The internal form of anthrax known as "woolsorters' disease" was next considered. Dr. Greenfield pointed out the far greater difficulty usually met with in the examination of the organs for bacilli in man, owing to their relatively small number and the length of time which must usually elapse before the post-mortem examination—a fact which always increased the difficulty in discovering them. After briefly adverting to the principal changes found in the organs as described in the previous lecture, these especially consisting of ecchymoses in the trachea and bronchi, great engorgement of the bronchial glands, mediastinal cellulitis, and pleural effusion, he described in detail the microscopical changes found in these cases. In two of the most complete cases, in which he was able to examine nearly all the organs of the body, he found the following conditions. In the lower part of the trachea and larger bronchi masses of bacilli were found occupying the lymphatic plexuses of the mucous and submucous tissue, and extending to near the surface of the mucous membrane. In some parts these were almost unattended by any marked change in the surrounding tissues; but where the change had proceeded to any extent, marked inflammation was present. Of the earliest changes observed, hæmorrhage into the mucous membrane and hæmorrhagic exudation upon its surface, leading to detachment of the epithelium, were the most common, in some cases the epithelial layer being raised entire, so as to form a sort of bulla on the surface. In the more advanced stages the entire mucous membrane was infiltrated with blood, so as to form a raised area, the deeper parts of the mucous membrane showing signs of inflammation, and being crowded with bacilli. No distinct ulceration was anywhere observed. Dr. Greenfield was also able to trace the course of absorption of the virus, as indicated by the presence of masses of bacilli along the lymphatics surrounding the arteries and bronchi, where they were found in some places in great abundance, whilst in other parts of the lung they could not be found at all, or only one or two here and there. In the bronchial glands, which in the majority of sections examined were completely infiltrated with blood, bacilli were found, but not in great abundance except in the bloodvessels of the cortical part, which were in many cases plugged by bacilli. The glands most especially affected were those situated at the bifurcation of the trachea, and might have become so by direct continuity from the larger bronchi. Hence Dr. Greenfield thought it probable that the primary affection was that of the bronchial mucous membrane, and that both the glands and the general system were secondarily involved. In the lung nothing special was found beyond some collapse, due to bronchial obstruction and to the pleural effusion, and in some parts commencing broncho-pneumonia. In other cases there were areas of hæmorrhage, corresponding with those seen in the lungs of lower animals when the arteries are obstructed. In the other organs no special changes beyond what are common to most febrile diseases were discovered, except where hæmorrhage had occurred in various organs. Bacilli were found scantily distributed in the blood in sections of vessels.

Passing, then, to the question of the source and mode of entrance of the virus, Dr. Greenfield described the mode of woolsorting and the conditions under which infection occurs. Neither microscopical examination nor experiments had been able to prove that the wool was the source of the infection, but the circumstantial evidence appeared conclusive that such was the case. Nor had experiments with the water in which wool had been washed been more satisfactory. But the difficulties in the investigation were so great that a negative result was not surprising.

As to the channel by which the virus enters the system, although the bronchi or lungs would appear most probable, from the origin of infection, course of symptoms, and results of pathological investigation, it could not on these grounds alone be conclusively adopted, for some cases of inoculation by the skin presented very similar pulmonary lesions. But skin inoculation in man gave rise to a definite local lesion; this might therefore be excluded. Inoculation in some part of the alimentary or respiratory tracts remained therefore for consideration.

Experiments by Böllinger, Pasteur, Toussaint, Feser, Chauveau, and others, have shown that even large quantities of anthrax virus may pass through the alimentary canal of susceptible animals without injury, unless some irritant particles capable of causing abrasion are present. Buchner has recently shown that large quantities of spores mixed with the food of white mice may pass unaltered through the greater part of the alimentary canal, being gradually destroyed by digestion, but producing no results, whilst inoculation with the contents of their intestines in small quantity causes fatal effects. Similar experiments which Dr. Greenfield had made by feeding with infected food had a like negative result.

On the other hand, it has been conclusively shown that inhalation of spores will give rise to infection, though Buchner's experiments seem to show that the result is very largely attributable to the material in which they are conveyed, and that powdered charcoal and talc are by far the most suitable. The short particles of hair found in the wool- or hair-dust would, Dr. Greenfield thought, furnish a similar irritant vehicle in inhalation of infected hair. Moreover, if inoculation had occurred through the alimentary canal the lesions produced would probably have had some resemblance to those in Wagner's cases of "intestinal mycosis." From these considerations Dr. Greenfield considered it almost conclusively established that the majority of cases of "woolsorters' disease" are a form of anthrax produced by inoculation through the mucous membrane of the bronchi, a "bronchial" as distinguished from an "intestinal" mycosis. Other cases might show that inoculation sometimes occurred through other channels. The subsequent course of infection was probably through the lymphatic and bronchial glands. Dr. Greenfield had not found any particles of hair in the alveoli in scores of sections of the lungs in these cases.

With regard to the other changes found, the pleural effusion might probably be due partly to an altered condition of the blood, but still more to the complete obstruction of the bronchial lymphatic glands. It did not appear in any case to be inflammatory, nor was any other obvious cause present. Probably this great pleural effusion was often the immediate cause of death.

As to the symptoms observed, these appeared to be closely related to the changes discovered; very probably the obstinate vomiting sometimes observed was due to implication of the vagus and phrenic nerves in the mediastinal inflammation, and this might also account for the rapid and irregular action of the heart. The convulsions had been attributed to asphyxia, but might equally be due either to direct affection of the brain, toxæmia, or uræmia, the latter being indicated by the condition of the kidneys.

The incubation period was next discussed, and the statistics from a large series of experiments by various observers, and by Dr. Greenfield himself, were collated, as well as cases in man. From these he concluded that in many cases a period of four and a half or five days elapsed between the exposure to infection and onset of symptoms in man, a longer period than usual in lower animals, but that there was probably great variation in this respect, and the known facts were not yet sufficiently numerous to justify an absolute conclusion.

As to the diagnosis of the disease; with our present knowledge it must largely depend on known exposure to infection, and this very probably accounted for its not having been recognised in regions where it almost certainly existed. From ordinary acute pneumonia it might be usually distinguished by the absence of early elevation of temperature, the absence of the usual physical signs, and of rusty sputum, the marked depression out of proportion to the local symptoms, and the rapid cyanosis, usually with signs of double pleural effusion. But in the very rapid cases death often occurred whilst the case was still regarded as one of ordinary bronchitis, and in the prolonged cases secondary bronchopneumonia might occur, and complicate the diagnosis. Moreover, it might simulate various unusual forms of latent pneumonia associated with renal and other diseases.

The diagnostic value of anthrax bacilli in the blood had been overrated, for very frequently they might be so limited to the affected regions until very near the time of death, or shortly after, that repeated examination of the blood would fail to detect them in the earlier stages of the disease. Hence it was but very rarely that their discovery would serve to establish the diagnosis. After death, before decomposition occurred, the presence of bacilli of the size and form of anthrax bacilli, without other bacteria, would be distinctive, but after decomposition had set in the presence of similar bacilli with other bacteria was inconclusive. The only certain test, inoculation, was also usually negative when decomposition had set in. But if on cultivation of blood in the warm stage the bacilli do not develop, but degenerate, they are probably not due to decomposition, as the bacilli formed in putrefying blood will, under these conditions, continue to develop in the presence of other bacteria. Dr. Greenfield also discussed other points relating to the distinction of anthrax bacilli.

In conclusion, he remarked that the observations which he had detailed, when combined with recent researches on the contagion of malarial fevers, relapsing fever, and fowl cholera, were of great suggestive value in relation to the pathology of contagion, making some of the difficulties hitherto felt in accepting the bacterial view of contagion much less than they had hitherto appeared. At the same time we ought not for a moment to allow any discovery, however important, to be extended beyond its own special and legitimate conclusions with regard to the particular disease in question. But these observations should lead to the investigation of other contagia along the lines indicated by determined facts.

It was now clearly shown that the diseases in question followed the same laws of non-recurrence or modified recurrence as other specific fevers; that they were attended by specially localised and specific lesions. The bacteria forming the contagium follow special laws of growth and distribution within the body, which are not explained by any mere chemical affinity or physical qualities. They must be regarded as parasites, which both within and without the body are selective as regards their host and the parts which they affect, and in the changes they undergo and produce, and are governed by definite laws specially related to the class of animals and the individuals which they infest. External to the body they may, under suitable conditions of growth, become modified in their properties, or even lose their morbific action. Within the body they may be innocuous, owing to the insusceptibility to their action, and may be simply destroyed or excreted. They may also be periodical in their times of diffusion, as well as selective in point of locality.

LECTURE V.

This lecture took the form of a demonstration, with remarks, of microscopical specimens, and of a series of microphotographs prepared by Dr. Maddox, which were shown with the limelight by Dr. W. H. Stone.

The series of photographs illustrated the changes undergone by the anthrax bacillus in its growth, and the continuance of the characters unaltered through a series of generations of cultivation. Together with these, photographs of the blood and the fluids from cases of human anthrax ("woolsorters' disease") were shown; and also organs of various animals dying of anthrax.

The microscopical specimens were also illustrative of the subjects of the lectures, upwards of sixty microscopes being shown. Complete series of cultivations of the anthrax bacillus under high powers were exhibited, and other bacilli liable to be mistaken for them. Other series of preparations showed the changes found in splenic fever in the lower animals, and those discovered by Dr. Greenfield in "woolsorters' disease."

Clinical Lecture
ON THE
DIAGNOSIS & TREATMENT OF RINGWORM.

Delivered at St. Mary's Hospital Medical School,

BY MALCOLM MORRIS, F.R.C.S. EDIN.,
JOINT LECTURER ON DERMATOLOGY.

GENTLEMEN,—Ringworm, no matter what part of the body may be affected, is essentially a localized eczema produced by a local cause. The local cause is a microscopic fungus which has a peculiar affinity for the epidermic structures of man and certain animals. There are some who deny that the phenomena seen on the skin to which we are accustomed to apply the term ringworm are due to this vegetable growth; but I will ask you to accept the theory as established, inasmuch as it is the opinion of the majority of dermatologists, both English and foreign.

During my observations I will ask you, then, to assume that this fungus—which is known as the Trichophyton tonsurans—is the primary cause of all the changes on the skin known as ringworm. It is found that these changes differ in appearance according to the part on which the fungus is deposited, and the fact is clearly due to the anatomical differences of the epidermic structures. But in spite of these differences the principle involved is the same—the fungus, as a foreign body, acting as an irritant and causing an eczema. The strongest argument in favour of the parasitic theory is the pre-eminently contagious character of the disease. We find that if a child suffering from ringworm be accidentally admitted into a school, after a short interval several of the other children give evidence of having been attacked in a similar manner. Occasionally, however, cases are met with in which children kept under close supervision develop ringworm, although there is apparently no history of contagion. In such circumstances I think there is little doubt that the disease has been caught from domestic animals, usually cats. As regards the physical characters of the parasitic plant, I refer you to the text-books on the subject, and especially to the excellent description by Kaposi in the fifth volume of Hebra, published by the New Sydenham Society. To-day I wish to call your attention to the various stages and changes produced by its presence, and to consider what are the indications for treatment in consequence.

In the initiation, fungus is carried in minute particles either in the air (Bazin) or by means of the clothes on to the epidermis; here it is deposited, and, if the soil is suitable and there is sufficient warmth and moisture, it commences to grow. Passing then between the horny cells of the epidermis, it finds its way into the deeper layers, where by the irritation of the more organised cells it sets up the first stage of a simple inflammatory process—viz., hyperæmia. A red spot, then, is the first subjective symptom in ringworm in every case, whether the part be covered with hair or not. Next in order comes the formation of a ring of inflammatory papules, the second stage of a true eczema, and the circle continues to widen with the growth of the fungus. The acute inflammatory symptoms may here cease, or indeed, as is the case in all eczemas, they may abort at any stage as a result of a removal of the cause. But should the condition become more intense, the papules will become the seat of vesicles; and although these vesicles have nothing peculiar in themselves, the fact of their being distributed more or less in a ring will lead to the suspicion that the disease is ringworm. Authors have recognised the three stages I have mentioned, and have given such descriptive names to the disease as tinea maculosa, tinea papulosa, and herpes tonsurans. As the ring spreads we shall find that the hyperæmia within the centre disappears, and in consequence of the interference with the growth of the cells a branny desquamation will be observed on the surface. In addition to the foregoing appearances, if the part attacked be hairy, the hairs themselves not at first affected speedily become diseased. The fungus may be deposited either on a hair or in the mouth of a hair-follicle. Thus it may grow downwards into the follicle or it may get there by extension from the deeper layers of the epidermis. As soon as it reaches the deeper part of the follicle it interferes with the nutrition of the hair, and thus causes it to break off a short distance from the mouth of the follicle, leaving a projecting stump. This stump is usually split or twisted, and has lost its natural healthy appearance; moreover, it lies but loosely in the follicle.

A recent patch of ringworm of the scalp, for example, can easily be diagnosed by the raised red ring of papules, some of which may be vesicular, with a more or less pale, slightly pigmented centre, covered with branny desquamation and short broken hairs that are readily extracted.

To pass now to the more chronic and obstinate forms of the disease. As far as English ringworm is concerned, the parts attacked are limited to the scalp, for the disease when found on non-hairy parts is quickly and easily cured; I am now speaking of English ringworm only. There is, I have understood from Indian medical officers and surgeons who have practised in China and other parts of the East, a variety of the disease which attacks the body, and is most inveterate and difficult to cure. Why this is the case I cannot tell you, but one would be inclined to imagine that the heat and the moisture on the skin would so favour the growth of the plant as to make it reach a higher state of organisation than it attains in this country. At all events, the eczema produced is undoubtedly the same, though of a more severe type, and the fungus is harder to destroy.

Acute ringworm may pass into one of two conditions:—1. It may become pustular. 2. It may become dry and squamous. Pustular ringworm of the scalp is a most important stage of the disease to recognise, as there is danger that the cause may be overlooked. It may also assume either a superficial or a deep form. If superficial, the appearance is that of pustules at the mouths of the hair-follicles, which burst and cause fresh pustules to be produced by the pus being transplanted to other parts of the head. Thus a contagious impetigo, or porrigo, is the result. As the pus dries large yellowish scabs are formed, from beneath which the pus exudes. When the scabs are removed some of the short broken hairs come away with them, and small bald patches are left in consequence. In the deep-seated variety the pus is formed in the substance of the follicle, and as it passes to the surface through the neck of it, by mixing with the sebaceous matter, it becomes somewhat thinner than ordinary pus. The effect of inflammation in the follicles is to cause the part to become raised and tender, and to have the appearance of a subcutaneous abscess. The condition is known as *kerion*. As the process continues the hairs fall out, oftentimes leaving permanent bald patches.

We now come to the second variety—viz., squamous ringworm. This is the commonest and the most chronic form of the disease. Sometimes it is seen in small localised patches corresponding in size to the original acute patch, at others it will cover the whole scalp. In the latter case it may be called by a term I have employed elsewhere—"diffuse ringworm."[1] In both these forms all signs of acute eczema have disappeared, but in their place has been produced a dry squamous eczema. The localised patches are easily recognisable, resembling, as Kaposi remarks, badly executed tonsures by reason of being covered with short broken hairs. The "diffuse" variety, on the other hand, is very often overlooked and treated as a simple eczema, in which case it will probably last for years. Gentlemen, I should advise you to be exceedingly cautious before you give a certificate that a case of ringworm is cured, for you may by carelessness in this respect cause endless trouble to a great number of people. It is when describing this variety that a word of caution needs to be spoken, for although you would not be likely to give a certificate if you saw a well-defined patch, you might very easily be led to agree with an anxious parent who had learnt to call the case simple eczema. "My child has had ringworm, and now we cannot get rid of the scurf on the head," is a remark I am told constantly, and as constantly after making a careful examination with a little patience do I succeed in finding fungus. The disappointment of the parents on being confronted with such a result can be imagined, for in many instances it has transpired that they have been told by other medical men that the case was well. In fact, even in cases where I have spoken with authority from the revelation of the microscope my opinion has been doubted, the former faulty but favourable view had so strongly possessed the parents. Diffuse ringworm is the most chronic and the most difficult to cure. In this I am supported by the opinion of the distinguished medical officer of Christ's Hospital, Dr. Alder Smith, who in an able article,[2] recently published, says, "Especially would I call attention to a variety I call 'disseminated ringworm,' one rarely diagnosed, and the most chronic and difficult to cure."

It is my wish to-day to make this troublesome condition clear to you, for I am certain that if it were recognised by surgeons generally, we should hear much less of ringworm in our schools. It is extremely contagious. I think I shall be well within the mark if I say that, if left untreated, it is a more contagious condition than any other stage of the disease. The reason is that the scalp is so dry that the particles are easily disseminated in the air, and settle on the skins of other children.

Here I would digress for a moment to consider the class of persons principally affected with this disease, as it will assist us both in our diagnosis and treatment. Children are much more prone to take it than adults, and especially on the scalp. I have seen only three cases so situated in adults. One was a governess who caught it from the children she had under her care. Occasionally in adults it attacks the beard, when it deserves the name of sycosis parasitica. It is not at all uncommon for adults to get it on the body, and it usually occurs when they are attending to children who have it on the head. As regards the children themselves, I believe it depends greatly on the character of the hair and epidermis—first, as to whether they get it at all, and, secondly, as to the length of its duration. To explain my meaning more clearly, I have grouped children into three classes:—

	Hair.	Eyes.	Epidermis.
1	Black or dark brown	Dark brown	Thick
2	Brown (medium)	Blue-grey, grey-blue, or grey-brown	Medium
3	Very light brown, golden or colourless	Light grey or blue	Fine skin with thin epidermis

The first class but rarely suffer from ringworm, the third take it easily and usually have it severely, very often the pustular variety. The second class, both as regards severity and readiness of infection, stand midway between the other two classes. If, therefore, you get a child answering to the description of either the second or third class with either a pustular or dry scaly disease limited to the scalp, I would advise you to suspect ringworm.

---

[1] Manual of Skin Diseases, p. 269.

[2] THE LANCET, January 10th, 24th, 31st, 1880.

To return to the diagnosis of the diffuse squamous variety. The whole, or a greater part, of the scalp is covered with white powdery scales that fall off easily, the hair is thin, dry, and lustreless, while here and there a few short broken hairs are to be found, which are easily extracted. *These short hairs are often extremely difficult to find, and because, in a superficial examination, you cannot at once find them, it will not be right to conclude that they do not exist.* At times I believe they are so short that their ends are hidden amongst the loose epidermis. In order to find them, instead of picking with forceps, scrape the part gently with a knife. By this means you will be able to get some of the small stumps. Place the stumps, together with portions of the epidermis, in liquor potassæ, and examine microscopically, and you will find fungus.

(To be concluded.)

THREE CASES OF SUDDEN OBSTRUCTION OF THE ABDOMINAL AORTA BY ANEURISM; WITH REMARKS.

BY J. S. BRISTOWE, M.D., F.R.C.P.

(Concluded from page 133.)

CASE 3.—*Aneurism of upper part of abdominal aorta; rupture and subperitoneal extravasation of blood; aortic obstruction; albuminuria and infarcts in kidney; partial paraplegia; death.*—W. L——, an engine-driver, forty years of age, came under my care on June 17th, 1880. He had had clap and syphilis, but otherwise had enjoyed good health till the commencement of his present illness. In 1865 he went to India as an engine-driver, and continued well until eleven months ago, when he began to suffer from pain in the lumbar region, associated with constipation. The pain soon became so constant and severe as to wholly incapacitate him for work. He went first into some local hospital, where he was treated for lumbago, without relief; and subsequently into the General Hospital at Calcutta, where he was treated mainly with purgatives, and derived, as he thought, some benefit.

On admission, he was a florid, healthy-looking man. He complained of pain in the left lumbar region, not constant, but coming on in paroxysms at irregular intervals. It was always worse at night, and was aggravated by walking or even sitting up in bed. It was generally of a dull, aching character, but at times becoming acute and lancinating. He had also an occasional burning sensation running down the fronts of both thighs to the knees. The pain prevented him from sleeping. He had slight tenderness in the left lumbar region, and over the left sacro-iliac articulation, but no enlargement. Tongue coated; appetite poor; bowels constipated, the motions being hard and scanty; heart sounds and action normal; pulse 66; lungs apparently healthy, no cough; abdomen not distended, nor tender on pressure; no tumour detected in it; urine, sp. gr. 1018, phosphates, no albumen. Temperature 99°.

He remained much the same until the 26th. The pain continued off and on with extreme severity, and was generally referred to a region a little above the centre of the crest of the left ilium; but he had also pain in the back, and at times pain across the abdomen below the umbilicus; he also had an occasional sense of numbness down the front of both thighs to the knees. The symptoms were relieved by the subcutaneous injection of morphia, and the application of a blister. The urine continued in fair abundance, of rather high specific gravity, and free from albumen.

26th.—About 8 A.M. had a very severe attack of lumbar pain, lasting for about half an hour, and then relieved by a morphia injection. He rolled himself about in bed, buried his face in the bedclothes, and cried out in agony. The pain was referred to both lumbar regions, scarcely extending into abdomen, but running down both legs, mainly the left. No sickness during attack. The temperature remained normal.

27th.—No urine passed for twenty-four hours. During the morning about three ounces were voided. It was thick, contained two-thirds albumen, and, microscopically, large granular casts, blood casts, free blood cells, and dumb-bell crystals of uric acid. The temperature varied during the day from 100° to 101·4°.

28th.—Passed six ounces of urine in the last twenty-four hours. Temperature in the morning 98·1°; in the evening 98·6°.

29th.—Passed seven ounces of urine in the last twenty-four hours. It still contained albumen, blood, and free blood cells. No casts or crystals discovered. He does not complain much of lumbar pain; but he has severe pain extending down front of left leg, and seems to have some difficulty in walking. Temperature normal. Under the use of morphia he has been free from paroxysms of pain since the 26th.

30th.—In the morning it was noted that his tongue was dry and brown; that his bowels were confined; that he had much pain in abdomen and down left leg, with occasional numbness in both feet; and that he had only passed four ounces of urine in the previous twenty-four hours. The specific gravity was 1022; it contained half albumen and blood. Temperature 98·6°. Noon: Was attacked very suddenly with increase of lumbar pain, slight sickness, and collapse. When the house-physician, who was sent for, arrived, the following was the patient's condition:—"Deadly pallor of face and lips, and rest of body. Pupils equal, small. Respirations moaning; pulse 204, scarcely perceptible. Complains of great pain in lumbar region and down legs. A diffused tumour, which has appeared since the morning, is felt in the left iliac region. No pulsation or bruit detectable over tumour or in abdomen, and no pulsation to be felt in arteries of lower extremities. Legs cold, but not colder than rest of body. They are numb, and he can scarcely move them. Can move right better than left." A little later he complained of a burning sensation in feet and inner side of thighs. Temperature 97°. 1.15: Lips and face corpse-like. Cold sweats. Pulse 122, barely perceptible; respirations sighing, but not frequent. He has a little hiccough. No urine passed. Has had no pain since morphia injection given about an hour ago. 1.50: Eyes fixed; pupils dilated; pulse not to be felt; occasional spasmodic startings of arms. Died at 2.10.

Post-mortem, July 1st.—Body fairly nourished. Chest: A little serum in pleuræ; lungs healthy; pericardium and heart healthy, the latter weighed thirteen ounces; thoracic aorta healthy. Abdomen: On opening the abdomen a large effusion of blood, in the form of a dark, soft coagulum, was found in the subperitoneal tissue on the left side, chiefly abundant in the neighbourhood of the left iliac fossa, and extending thence beneath the peritoneum of the abdominal wall anteriorly. It was not very abundant immediately in front of the spine. A large tumour was now discovered mainly on the left side of the abdomen, but extending across the median line to the right, beneath the liver. It was somewhat like a kidney in shape and suggested a renal tumour. On careful examination, however, the left kidney was found simply pushed upwards and forwards and resting on a large soft mass behind it. The tumour consisted partly of an aneurism of the abdominal aorta and partly of effused blood, the consequence of its rupture. The aneurism was saccular and came off from the posterior aspect of the aorta just where it gives off the cœliac axis and superior mesenteric. Its orifice of communication with the aorta measured two inches longitudinally. The inner coat of the aorta could only be traced for a short distance into the sac, and ended by a free irregular edge. It was not possible to say exactly how far the aneurism extended, or where the clot due to the aneurism ended and that which resulted from the rupture commenced, for the old and new clots were a good deal intermingled. The quantity of hard partially decolorised clot showed, however, that the aneurism must have been a large one, as also did the extensive erosion of the vertebræ which was present. This involved the last two dorsal and upper three lumbar vertebræ. None of the arteries springing from the abdominal aorta nor the aorta itself was plugged with clot and indeed they were pervious. But the disarrangement of clot in the aneurism and the pressure of the accumulated blood around not improbably caused more or less complete obstruction to some, at any rate, of these vessels. The left renal artery, from the stretching and displacement which it had undergone, was especially likely to have been rendered impervious. Liver and spleen were healthy. Right kidney somewhat congested, otherwise healthy. The left kidney was large and contained several large well-defined hæmorrhagic infarcts; one, occupying one-quarter of the organ, was pinkish-white in colour, and not harder than the rest of the kidney. Around it was a rim of very slight congestion.

Remarks.—The opinion first entertained by those under whose care the patient came, with respect to the first of my three cases, was that he was suffering from heart disease, and that the aortic obstruction, which was manifestly present, was due to embolism. This view I could not accept, because, first, in my opinion there was no evidence of heart disease, at any rate of such heart disease as could give rise to an embolus sufficiently bulky to occlude the aorta; and, second, according to my reading and experience, such sudden obstructions are generally, if not always, owing to the presence of aneurism. My own belief was that the patient, suffering from aortic disease, had suddenly experienced rupture of the internal coat of the artery at its highest part, with the development of a dissecting aneurism, an occurrence which is not altogether unfrequent, and is productive of such symptoms as the patient presented. The actual cause of obstruction, however, was somewhat different: it was the gradual encroachment of the clotting which was taking place in the lower of the two aneurisms on the channel of the adjoining portion of the aorta, and either its subsequent displacement or the rapid coagulation of blood in the narrow chink which the older clot had left. Paraplegic symptoms have generally been observed in these cases; but here the paraplegia was as extreme and as complete as it would have been had the lower part of the spinal cord been the seat of general softening. There was total loss of muscular power, total absence of sensation, complete abeyance of reflex excitability, and involuntary discharge of fæces and urine. Moreover, nutritive lesions had appeared rapidly. Some of the sores, which ultimately became sloughy, were no doubt due to the application of hot bottles; but this was not the explanation of the large sacral bedsore, which was already extensive at the time of admission, or only four days from the commencement of his illness. The alkaline, albuminous, and bloody urine soon becoming offensive, was, doubtless, due to early inflammation of the bladder, which, increasing in intensity up to the time of death, induced at that time partial gangrene.

In the second case, as in the first, I was inclined to attribute the aortic obstruction to the sudden formation of a dissecting aneurism, commencing probably in the aortic arch, a view which seemed to me confirmed in some degree by the development as the case went on of bronchial symptoms. I thought in fact they might be due to obstruction of the bronchial arteries by the clot accumulated between the internal and external walls of the artery. As a matter of fact, the case, pathologically, was almost identical with the last. In this, as in the other, paraplegia was a striking symptom. But here the loss of power and of sensation was incomplete, and incontinence of the evacuations was present, if at all, in only a very slight degree. But other phenomena of much interest were observed. In the first place, it will be recollected that the patient had an attack of diarrhœa on the morning of the day on which he was taken ill; that this recurred in association with much pain at the anus at the very moment when from other symptoms we have reason to suppose that the aorta became blocked; that pain at the anus, with discharge of blood, continued to be one of the features of the case up to the time of death; and, further, that marked inflammation of the mucous membrane of the rectum was discovered post-mortem. There can be no doubt, I think, that the pain and discharge of blood which occurred latterly, and the rectal inflammation, were due directly to the impeded circulation through the vessels of the part. Is it not probable, then, that the diarrhœal attack which attended the onset of his fatal illness, and probably that which occurred in the morning, may have been the immediate consequence of circulatory default? In the next place, total suppression of urine seems to have succeeded to the accident for some hours, and during the remainder of the patient's illness the urine continued scanty, and underwent some remarkable changes of quality. Three ounces were withdrawn from the bladder at the end of the first ten hours, none having been voided meanwhile. This was absolutely healthy. During the next twenty-four hours he passed a few ounces into the bed, and an ounce drawn off at the end of that time by the catheter contained three-fourths albumen, but no blood. Subsequently he passed on two occasions collectively about nine ounces and a half of urine, which was not only albuminous, but alkaline and offensive, and contained pus-cells and bacteria. It will be recollected that at the post-mortem examination no passage existed between the renal arteries and the aorta above the seat of obstruction, and that, therefore, any circulation of blood through the kidneys could only have been effected circuitously through vessels distributed to their capsules; that the kidneys were large and congested, and that the mucous membrane of the bladder presented ecchymoses. From a consideration of the above facts, it will be admitted, I think, at any rate as probable, that in consequence of the renal arterial obstruction temporary suppression of urine took place, and that which was first removed, and was healthy in quality, was the urine already contained in the urinary passages and receptacles at the time of the accident; that later, owing to the partial establishment of collateral circulation, the secretion of urine began to be re-established, but that this (as might have been expected) was loaded with albumen; and that later still vesical inflammation arising, as in the first case, the effects of that condition in rendering the urine alkaline, purulent, and offensive became superadded.

The third case I confess I did not understand until the rupture of the aneurism took place and caused a series of symptoms the meaning of which was unmistakable. I was not misled by the history (which originally, much more than as I have placed it before you, suggested affection of the bowels), into thinking that the patient was suffering from any form of bowel disease. But I halted between renal calculus, malignant disease, either of the kidney or in its neighbourhood, and aneurism of the aorta. And when latterly the urine became scanty, and contained blood, albumen, and uric-acid crystals, the renal interpretation of the case began to acquire predominance in my mind. I acknowledge, however, that a careful consideration of all the facts of the case, as detailed in my notes up to the time of rupture, especially if interpreted by the light thrown upon them by the other two cases, might probably have led me to an accurate diagnosis. It will be recollected, however, that no abdominal tumour had been detected by myself or by others who had examined the patient. The points of chief interest in this case are, that (as in the other two) obstruction of the aorta, and cessation of circulation in the parts below, were attended with paraplegic symptoms; and that (as in the last case) obstruction to the renal circulation caused almost complete suppression of urine, such urine as was secreted becoming at the same time highly albuminous. In this instance it presented granular and bloody casts. There was no absolute obstruction of either the aorta or of the large vessels springing from it in the neighbourhood of the aneurism at the post-mortem examination; but the accumulation of blood around them was quite sufficient to have caused obstruction by pressure or stretching. The fact that before death his lower limbs became absolutely pulseless and partly paralysed renders it certain that the aorta was actually obstructed; the fact that the left kidney was congested, and presented large so-called "infarcts" of recent development (such as are only caused by arterial obstruction), render it certain that the left renal artery was actually obstructed; and both together make it not improbable that there was more or less obstruction also of the right renal artery, and may be of the cœliac axis and superior mesenteric also.

In conclusion, Gentlemen, permit me to make a few observations which suggest themselves to me from the consideration of these and of other like cases. Sudden obstruction of the aorta appears to produce not only arrest of circulation in all those parts which derive their blood-supply from the arteries which are given off at and below the seat of obstruction, but to cause also paraplegic symptoms, such as loss of voluntary power, loss of sensation, loss of reflex action, and incontinence of urine and fæces, closely resembling those of paraplegia arising from direct disease of the cord, and which, like them, vary in their severity in different cases. To what are these symptoms to be attributed? I suspect that the explanation is twofold: that it is partly due to sudden arrest of those nutritive processes on which the preservation of vitality depends throughout the various tissues whose functions are impaired or lost; and that it is partly due to the fact that there is direct interference with the nutrition of the lower part of the cord from obstruction of the arteries furnished to the cord from the aorta below the seat of obstruction.

But it is clear also, if the aortic obstruction be above, or involve the renal and mesenteric arteries, as happened in the three cases which I have adduced, that the organs which these vessels supply should suffer in their nutrition and innervation, and consequently functionally, just as the skin and muscles suffer, and that special symptoms might hence be looked for in connexion both with the intestines and with the urinary organs. My cases seem to show that it is so. Obstruction of the mesenteric arteries, though perhaps immediately inducing anæmia of the bowels, soon leads to congestion, stagnation of blood, inflammation, and gangrene. This seems to have actually occurred in my second case. Obstruction of the renal artery might also at first cause anæmia of the kidney; but soon through small collateral vessels blood finds its way into the organ, which becomes congested, and owing to impaired nutrition the seat of so-called "infarcts." That these phenomena were present, at any rate, in two of my cases seem certain. For suppression of urine in both cases followed the obstruction, and the urine which was subsequently passed was albuminous, and contained blood. Again, one would expect the bladder to suffer in the same way as the rectum, and from the same cause. In every case the bladder was actually inflamed, and the ammoniacal condition of the urine which supervened in two after a time was probably due to this circumstance.

I have referred in my comments on one of my cases to the supervention in their course of the nutritive lesions, which are apt to follow spinal disease, and suggested that the early appearance of bedsores and inflammation of the bladder might thus be explained. I need scarcely say, however, that here we have a complex problem to deal with, and that, although direct nervous influence may have had some effect in producing these conditions, it is at least as probable that they were due to arrested circulation and tendency to death of the parts.

Another matter to which I may refer is the duration of cases of aortic obstruction. It might be supposed that, as is warranted by the cases I have adduced, early death must in all cases ensue, and that anything like recovery would be impossible. That permanent recovery should take place is, of course, from the nature of the disease, impossible. But there is a tendency more or less pronounced for collateral circulation to be established, and thus for parts that were cold and moribund, to resume their normal state. That tendency for the re-establishment of circulation and the restoration of function was shown by my cases in respect of the kidneys by the tendency to the re-establishment of the urinary secretion which actually occurred. But it was shown even more plainly by the restoration of warmth to the upper part of the legs, and by the limitation of gangrene in one of them to the toes and other parts of the feet. But this reinstatement is sometimes complete. I recollect a case in point, which was put on record in the Pathological Transactions by Dr. Swayne some years ago, and impressed me very much. It was that of an elderly gentleman, who had sudden obstruction of the aorta in consequence of the formation of a dissecting aneurism, and who presented many of the symptoms which my cases also presented. The circulation became re-established by collateral channels, and he recovered so as to be able to drive about in his carriage. But he died of pulmonary complication at the end of three months.

The last points which I intend to bring under your notice concern the circulation. It was mentioned that in two of the cases the pulse was full and bounding, and felt much like that of aortic regurgitation. I bring the tracing from one; it was alike in both. In only one of the three cases was a murmur detected in the abdomen. It was observed at the apex of the epigastrium, and was prolonged feebly from that point for two or three inches downwards. It presented peculiarities, which I have observed before, and to which I have called students' attention. Murmurs at the cardiac orifices correspond either to the systole or to the diastole of the ventricles of the heart; a systolic murmur never being continued into the diastole, or conversely. And if, as not unfrequently happens, cardiac murmurs are heard in the course of the arteries, these murmurs, as the case may be, correspond also either to the cardiac systole or to its diastole. Now, in my case, as also is the case with many aneurismal murmurs, and, in fact, as one ought to expect, the murmur, commencing with the percussion wave, was continued not only through the whole duration of the tidal wave corresponding to the cardiac systole, but somewhat modified in character beyond even the aortic notch, and into that portion of the pulse which corresponds to the cardiac diastole. In other words, the murmur being due to the onward passage of blood, continues so long as the passage of blood is sufficiently rapid to evoke sound, and that does not necessarily cease when the cardiac systole ceases.

Old Burlington-street, W.

FURTHER RESEARCHES ON

ETHYLATE OF SODIUM IN THE TREATMENT OF NÆVUS AND OTHER FORMS OF DISEASE,

WITH OBSERVATIONS ON ETHYLATE OF POTASSIUM.[1]

BY BENJAMIN WARD RICHARDSON, M.D., F.R.S.

THE introduction of sodium ethylate, like that of amyl nitrite, into the practice of medicine and surgery, was due to the researches on the amyls, ethyls, and alcohols, which I had the honour to carry out for my reports to the British Association for the Advancement of Science between the years 1863 and 1871. In observing the action of the more ordinary form of alcohol—the ethylic—on the blood and the tissues, it occurred to me to inquire what difference of action would occur if an alcohol was used in which sodium or potassium takes the place of the remaining atom of hydrogen which belongs to the water molecule present in the alcohols—that is to say, what would be the action of ethylic alcohol if the radical ethyl which replaces one of the hydrogens of the water was united with a metal like sodium or potassium, instead of hydrogen? The ethylates of sodium and potassium, sodium and potassium alcohols, were at that time well known as chemical substances; but they had not been used as medicinal agents, nor had their employment as remedies been suggested. It struck me, however, that they might come in as serviceable caustics, and at the same time as antiseptics.

To test their value in the last-named direction—I mean as antiseptics—I brought them into contact with fresh brain-substance taken from the newly-killed sheep, and found that they powerfully preserved the structure. I also noticed that when they were placed in contact with animal structures they were rapidly decomposed; they were oxidised. Soda or potash was produced, and absolute alcohol was *re*produced. When the ethylate thus employed was a concentrated solution, or when it was used in the form of crystal, the effect of the produced alkali was to maintain the softness or the fluidity of the structure acted upon. When the ethylate was much diluted with alcohol the effect was different; then the alcohol acted as an agent for producing rapid coagulation of the albuminous or fibrinous substance. This observation, which at first sight may appear of minor moment, turns out to be of considerable importance when the details of practice, in connexion with the ethylates, are under consideration—a fact which will be better seen further on.

The result of my experimental inquiry was to indicate that in the ethylates of sodium or potassium we had a substance which, brought into contact with colloidal tissue, would be decomposed into an active caustic in the nascent state, and into alcohol which, in the same state and at the same time, became an antiseptic, a styptic, and a pectiniser, or producer of coagulation.

Extending the inquiry to newly-drawn blood, I learned that by concentration of the ethylates I could hold the blood fluid, while by diluting them with alcohol I could cause immediate and firm coagulation. I learned, moreover, that I could change the character of the red corpuscle in the most determinate manner; that the corpuscle could be made to pass into a complete crystalline form by a strong solution; while by dilution it could be simply shrunken into a very minute and contracted condition.

The facts ultimately led me to think of applying the ethylates to living tissues as a method for removing vascular growths. I reasoned that when an ethylate was applied to a vascular growth the metal—sodium or potassium—would be oxidised and become a powerful caustic, while at the same time the alcohol that was reformed would fix the destroyed matter and the blood by the process of coagulation, and would at the same time prevent decomposition.

The choice of sodium or potassium alcohol was now before me, and ultimately I selected the sodium as the best for all practical purposes of the ordinary kind. The reason for this selection was based on the following experience:—My friend, Mr. Lord of Hampstead, had a patient who was suffering from three large vascular growths on the scalp, and in consultation with him I proposed to destroy one of these growths by means of potassium ethylate. The suggestion was adopted, and the destruction of the growth for the time was effective. The hæmorrhage which occurred was, however, so profuse and was checked with so much difficulty, that I determined in treating the other tumours to use the sodium ethylate preferentially. This acted well, and the destruction of tissue was accomplished without any trouble from loss of blood. The growths, in the end, assumed the malignant character, and the patient sank from the extension of the disease. The experience of the difference of action of the two salts, in respect to bleeding in this case, led me to propose the sodium ethylate as the safest, if not the most active, compound. It was in the first part of these inquiries that I used the ethylate of sodium with so much success in the treatment of a case of intractable nævus that had been under the care of my friend Mr. Gay. Mr. Gay was good enough to place that patient entirely under my charge and the recovery was perfect. As the Society is aware, a good many years elapsed before the employment of the ethylate came again under professional notice, through the admirable paper read before the Society, on the Treatment of Nævus, by our able colleague, Dr. John Brunton. From one occupation or another, the clinical use of the ethylate had, except on special occasions, passed out of my thoughts, until Dr. Brunton's labours revived it. Since then I have been more attentive to it, and have gained some further experience, which may, I hope, be useful to relate.

---

[1] Read before the Medical Society of London, on Monday, Jan. 17th, 1881.

In the treatment of vascular nævus (cutaneous) I have had since my last report nine cases, each of which has done well. They have all been in children, and some of them have been cases in which other modes of treatment had, previously, been tried. It may be well to give a brief review of these cases in order.

The first was an instance of the common form of nævus on the scalp in an infant three months old. After perfect recovery from vaccination, the treatment commenced in the usual way by the application of the ethylate over the growth, by means of the glass-rod. The nævus was small, not larger than a fair-sized hazel nut. The first application caused a dense scale to form, which was loose and removable on the fifth day. The ethylate was then reapplied, and five days later, when the new scale was removed, the nævus was reduced to the size of a small bean. It remained in this state during three further applications of the ethylate, being much longer under treatment than I had expected after the second application. On the seventh application it was nearly removed, and one additional touch a fortnight later completely removed it. No constitutional symptoms interfered with the course of the treatment, and no scar remained.

In the next example the treatment was almost identical both in respect to mode and to result; but as the patient was very restive and screamed extremely when the ethylate was applied, advantage was taken to make the application when the infant was in a deep sleep. The plan succeeded so well that I venture to suggest its general adoption in young children whenever the nævus is in a situation where it can be easily got at, and whenever an intelligent nurse or parent can be taught to make use of the solution in a safe and efficient manner. In the case in question the nævus was quite removed in the course of six weeks, and it can scarcely be said that any pain at all was inflicted. No scar has been left.

The third illustration was not so favourable as the two above named, although in the end the patient did well. The nævus, again on the scalp, was near to the anterior fontanelle, the fontanelle itself being large. A cerebral pulsation, distinctly marked, extended to the nævus itself. I judged at first that there was a communication from the external nævus to another vascular enlargement within the cranial arch, but this turned out to be incorrect. The child was eight months old, was pale and feeble, with a large head. The nævus originally was of the size of a small walnut, and very prominent. The first application of the ethylate gave rise to a large and firm scale of the usual kind, which was removable on the fifth day. The second application caused a great deal of pain, and the crust which formed remained for a week immovable. When the crust was at last loosened and lifted up, the nævus was found to be reduced in size, but excessively red and vascular. It was freely treated with the ethylate, and again a dense and firm crust resulted. Four days after this the crust was quite firm, and on the eighth day, as the crust was still immovable by the ordinary method of lifting it up with forceps, I, forgetful for the moment of my own instructions, directed the nurse to apply a poultice and bring the patient to me again when the crust was softened. Two days later the child was brought very unwell. It was feverish; temperature 103°. There was an odour of decomposition from the nævus, and a dark sphacelus. I immediately dried the part most carefully with absorbent wool, and applied ethylate freely, covering with dry wool lightly. The good effect was immediate; the decomposition was arrested, a new and firm crust was formed, and from that time the recovery went on favourably, the nævus being destroyed, and scarcely a scar being left. The error I made in this instance consisted in the use of moisture from the poultice. It was this which set up the decomposition, and it was the decomposition and the secondary absorption which set up the febrile condition. I name the fact, and the temporary blunder involved in it, in order to re-enforce the point of practice that in using the ethylate water must never, under any pretence, be introduced as an adjunct. The mention of that example leads me to name the further practical suggestion that the removal of the crust, or the attempt to remove it too quickly, is not a good plan. It is best to let the crust come away of itself, or, at all events, to become so loose that it can easily be lifted away. We may take it as a general rule that so long as the crust is firm the nævus is contracting. Now, therefore, instead of removing the crust entirely, I am content to take off those parts only which are loose, and then to apply another touch of ethylate over the parts that have been removed. Certainly, all violence in removal is essentially mischievous. It causes pain; it often causes bleeding; and it prolongs, instead of expediting, recovery. When the crust is depressed in the centre it may be pierced with a needle, and a little ethylate may be introduced through the openings. This plan answers excedingly well.

The next four succeeding instances of nævus treated with the ethylate presented no special features, except that in one of them there were two growths on the same patient. The question here was raised, whether it was best to treat both the tumours at the same time, or one at a time. The last-named course was adopted, and with very good results. The nævus first subjected to treatment was removed in twenty-four days, and after a week the other one, which was smaller, was removed in a little less than the same period of time. The four cases did well, and in one only is there any appreciable scar. The patients were all young. The youngest was six months; the eldest a little under two years of age.

I now come to two cases in which the treatment with the ethylate, though successful, was not so facile. The first of these instances was sent to me by my friend Dr. Stevens, of Norfolk-crescent, Hyde-park. The patient was a beautiful little girl in her second year, and the nævus was situated over the left eye involving the lid. The nævus was of the dimension of a fair-sized strawberry, and various attempts had been made to remove it without success. I commenced in this case by applying the ethylate very freely to a lesser portion, or, I had almost said, segment of the growth, for it was, to a certain extent, divided into two parts. When a fair crust was established on the part treated I applied the ethylate to the remaining part. After four applications I succeeded in getting the whole mass under a firm encrustation, and from the beginning to the end of the treatment, which lasted seven weeks, I forbore from ever forcibly raising the encrustation. Whenever I found a portion of the crust quite loose I lifted it away and reapplied the solution. In this manner the nævus was destroyed, and although a little trouble was for a few weeks experienced with one small remaining spot, in the end the cure was complete, and I had the satisfaction of hearing a few weeks since from the father of the patient that the eyebrow was appearing, that there was no scar, and that some remaining redness, which I had feared might be permanent, was passing away, so that the parts were assuming a perfectly natural colour. The size of the nævus in this case and its position over the eyeball made the treatment more than usually troublesome; but the result was a fair reward for all the pains that were bestowed. The chief difficulty consisted in applying the solution in such a manner as to prevent it from affecting the eyeball itself. Once, during a short and determined struggle by the little patient, a small portion of the solution did touch the conjunctiva, but I removed it instantly by a pouch of cotton-wool, and no mischief followed.

The last case of nævus to which I have to refer was in an infant about ten months old. The nævus was in the fore-part of the neck, and immediately over the larynx. It was of the size of a half-crown piece, and not much raised. It was troublesome to treat on account of two complications. In the first place, after the vascular structure seemed to have been entirely destroyed, it reappeared in small points not larger than the head of a pin. In the second place, whenever the ethylate was freely used, so as to destroy a large surface of the growth, a very peculiar, sharp, croupy cough was set up, which indicated the necessity of limiting the application. These obstructions, combined with the desire not to produce a scar, caused the treatment to be very prolonged, and to extend over several weeks. Fortunately it has, I hope, ended successfully, and I apprehend without leaving evidence of scar, though that remains to be proved.

(To be concluded.)

SIX CASES OF PARACENTESIS THORACIS.

By A. W. MAYO ROBSON, F.R.C.S.,
DEMONSTRATOR OF ANATOMY, LEEDS SCHOOL OF MEDICINE.

SINCE the subject of paracentesis thoracis in pleurisy with effusion has been thought worthy of being discussed lately by the Medical Society of London, the following cases I venture to hope may prove sufficiently interesting for publication, especially as they bear on the possibility of cure by once tapping, and on the danger of rapidly drawing off a large volume of fluid at one operation. Moreover, the cases have not been selected, but are reported as they occurred, being the only pleuritic effusions which I have had to treat in my own practice during the last two years.

CASE 1.—Mr. C——, aged thirty-two, with a phthisical family history, consulted me, saying that he had been well up to three weeks before, when he began to suffer from a "stitch" in the left side, that he was now very short of breath, and had difficulty in ascending a hill; his appetite had become impaired, and he was losing flesh rapidly. I found the left side dull as high as the inferior angle of the scapula, with an absence of breath sounds and vocal fremitus, but there was no disease of the lungs or other viscera. I ordered a blister to the side, and gave digitalis and iodide of potassium, but after a fortnight the fluid had reached the spine of the scapula. I advised a dry diet, and that as little fluid as possible should be taken, at the same time giving small doses of elaterium. For a few days the fluid diminished a little, but after a week it remained stationary, and my patient became tired of his rigid diet. I advised paracentesis, but, before operating, asked Dr. Clifford Allbutt to see the case with me. He fully endorsed my recommendation.

By means of the aspirator I drew off two pints and a half of clear straw-coloured fluid through the eighth intercostal space. My patient was at once relieved, and forthwith began to improve. Although a little fluid collected again during the next ten days, under the use of an iodine liniment externally and iodide of iron internally it became absorbed; and at the end of five weeks he went to Torquay for change of air. On returning a month afterwards he had gained 10 lb. in weight, and the lung seemed to have fully regained itself.

CASE 2.—Mrs. K——, aged thirty, with a family history of phthisis, told me that she had caught cold two weeks previously, and had been suffering from pain at the side and shortness of breath ever since. She had lost flesh and was looking distressed and haggard. The right side was dull up to the fifth rib, and presented the usual signs of fluid in the pleura.

A blister was applied to the side and digitalis, iodide of potassium, &c., were given, but the fluid still increasing, the dry diet treatment was adopted. No improvement resulting, tapping was advised, but as the patient and her friends said that she should not undergo an operation if it could be avoided, medicinal treatment and iodine externally were tried for several weeks, at the end of which time the dulness had reached to the clavicle, and the heart was pushed to the left; the pulse was small and intermittent, the lips were livid, and the patient had to be constantly sitting up in bed in order to breathe. At last she consented, and I drew off by means of the aspirator four pints and a few ounces of a clear straw-coloured fluid. The pulse at once became fuller, more regular, and slower, the heart assumed its normal position, the lividity disappeared, and she could bear to lie in the recumbent posture. Vesicular breathing could now be heard in the infra-clavicular region, but not below. Although her condition improved daily, some fluid returned, and a fortnight afterwards the dulness reached the mammary line; however, under the use of iodine externally and iodide of iron internally it gradually disappeared, and six weeks after the operation she was able to go into the country for change of air, there being a little dulness and some falling in of the right thoracic wall. After being eight weeks in the country she called on me, and I found she had gained 9 lb. in weight There was vesicular breathing all over the right side, and but for the slight falling in opposite the eighth, ninth, tenth, and eleventh ribs, no evidence was left of her attack.

CASE 3.—The above patient, Mrs. K——, continued quite well for fifteen months, when she caught cold, was seized with pain in the left side, and was in every respect similarly affected as she had been in the previous attack, excepting that she could now only bear to be on the right (sound) side. Effusion came on very rapidly, so that a week after hearing a friction sound over the front of the chest the dulness had advanced as high as the clavicle, and the heart had become slightly displaced to the right; the distress in breathing, though severe, was not so great as when the effusion was on the right side. She begged to be tapped, and I at once drew off by means of the aspirator and a large needle five pints of clear fluid. She was seized with a violent fit of coughing before the needle was withdrawn, became livid in the face, and breathed with great difficulty; for a few minutes I was very anxious, as the pulse was small and fluttering, and she seemed to be in great distress. I gave one-sixth of a grain of morphia by injection, which soon relieved her. From this time she had not a bad symptom, was out of bed in a fortnight, and able to leave for the country in a month. Two months afterwards she called to see me, and appeared to be in very good health; both lungs were doing good work, and the left side of the chest had not become depressed in the least.

CASE 4.—A. B——, aged thirty-six, got wet through, shivered and felt a pain in the right side; the temperature reached 102·6° and 103° for several days in succession, and there were the physical signs of pneumonia of the right lower lobe. A distinct crisis never occurred, the temperature for nearly a month rising each evening to 100° and 101°, and night sweats coming on. At the end of a month the dulness still continued, but as vocal fremitus had disappeared and he could only bear to lie on the sound side, I feared an empyema was forming, and explored by means of the aspirator. Finding the fluid clear, I drew off a pint and a half, giving my patient great relief. Some fluid returned, and at the end of three weeks I again drew off a pint, and in a fortnight three-quarters of a pint more, after which recovery was steady but sure, and he was well in three months from the commencement of his illness.

CASE 5.—Mrs. H——, aged twenty-seven, with a family history of phthisis, became debilitated by suckling, and caught cold. She called to consult me for a pain in the side which had existed for a fortnight, and for shortness of breath. On examination I found signs of fluid in the left pleura as high as the fifth rib. After twelve days' medical treatment, there being no improvement, but rather an increase of the effusion, I drew off a pint and three-quarters of clear straw-coloured fluid. She was at once relieved. After a few days a little fluid returned, but under the administration of iodide of iron and cod-liver oil, with the external use of iodine, it gradually disappeared, and she was able to go out in a month. Some dulness, evidently due to thickened pleura, remained for some time, and the lung expanded slowly, but at the end of three months (she having in the meantime spent a month at the seaside) I found the lungs doing good work, and the dulness scarcely perceptible.

CASE 6.—Miss M——, aged twenty-one, called to consult me, saying she had been ailing for several months, but that during the last few weeks she had been suffering from pain in the side and shortness of breath. She had lost flesh considerably. On examination, I found the left side of the chest dull up to the spine of the scapula, with the usual signs of fluid. As the temperature was 101°, I advised rest in bed and poultices to the side, and gave ammonia and chinchona internally; the fever subsiding in four days, she was ordered to take iodide of potassium with the bark mixture. At the end of ten days, there being no further improvement, but a slight increase of the fluid, I aspirated the chest in the sixth intercostal space, and took away two pints of clear fluid. My patient was at once relieved, and able to lie in the recumbent posture, she having been only able previously to be semi-recumbent and inclined to the right side. She improved rapidly under iodide of iron, with the external application of iodine liniment, was up in six days, and able to go out a fortnight after the tapping, feeling quite well in every respect, the lung having fully expanded, and very slight dulness remaining.

From the foregoing cases, and from others which I have observed in hospital and in private practice, I am as fully convinced that paracentesis thoracis, properly performed, is the best treatment in pleurisy with effusion, if the fluid be in any quantity, as I am that the administration of medicine to cause absorption is for the most part only waste of time to the doctor and disappointing and dangerous to the patient; for every additional day during which the lung is exposed to pressure, and time is allowed for cells to multiply in the fluid, lessens the chance of a complete cure, tends to permanently impair the lung, and to give rise to empyema with all its dangers; besides which, where there is extensive effusion there is more or less interference with the action of the heart, and great danger of sudden death.

Leeds.

SOME REMARKS ON THE TYPES OF PNEUMONIA WHICH ARE MET WITH IN NORTHERN INDIA AND IN NORTH-WESTERN AFGHANISTAN, ETC.

BY C. P. COSTELLO,
SURGEON-MAJOR, BENGAL MEDICAL DEPARTMENT.

As regards the northern and north-western parts of India these remarks are founded on twenty-one years' experience, and are offered to the profession solely because many of the facts are not as generally known as could be wished, and are therefore likely to be of use to practitioners whose lot may be cast in India, and to whom, on first commencing practice there, some knowledge of the peculiarities of pneumonia as found in Northern India may be useful.

As generally met with, this disease both in Northern India and in Northern and Western Afghanistan presents an asthenic type, and is often "latent." Persons who have suffered much from intermittent fever are, as a rule, more liable to pneumonia than others, and, on this account, there may be a "malarious" cause in such cases; it may also be added that just at the end of the fever season, before intermittent fever has ceased to fill the hospitals—that is, about the latter part of September and in October—this disease becomes very prevalent indeed. As usually seen, it runs through the first and second stages pretty regularly, but rusty sputa are not always found, and often the stethoscope detects the disease when there has been no cough or expectoration, pain in chest, &c.; it is then, of course, "latent," and this, as a complication, is most usually met with in "remittent fever," or in enteric fever, &c. When not "latent," it does not always commence at the base of the lung and travel upwards, but often begins in the middle of the lung, or perhaps at the apex, although the latter is rare. Frequently it does not pass beyond the first stage. "Latent" pneumonia is, as a rule, found to be in the second stage when first observed; this may be, and probably is, due to the delay which occurs before it is observed. Pleurisy, to some extent, is not an uncommon accompaniment of the disease, and it has often occurred to me that the case under treatment might be correctly named pleuro-pneumonia. At first I expected that this pleuro-pneumonia was contagious, and, acting on the idea, I made it a rule to isolate all such cases. In 1875 an event happened which confirmed me in this idea as to the contagiousness of some forms of pneumonia, and especially, and almost always, of pleuro-pneumonia. This was when I had charge of the 1st Punjaub Infantry at Dera Ghasi Khan, and before proceeding further, I should state that pleuro-pneumonia was very fatal amongst cattle in the Punjaub, and in the north-western frontier districts—more markedly in the lower Derajat—in that year. The 1st Punjaub Infantry, on being relieved by the 5th Punjaub Infantry at Abbotabad, marched through many of the affected districts to Dera Ghazi Khan; and the latter regiment, which took the same course to Abbotabad, had an identical outbreak, with even more fatal results, with that which I have now to describe as having occurred in the former. On joining the 1st Punjaub Infantry at Dera Ghazi Khan towards the end of March in 1875, the regiment was in a state of consternation at the number of deaths which had within a short time prior to my arrival occurred from "pneumonia." It was then rather warm at Dera Ghazi Khan, and there was not much variation of temperature in the twenty-four hours, or much difference between the day and night temperature, which made the continuance of the disease all the more inexplicable. At least from thirty to forty men had died from it in a few weeks out of a strength of about 550—as well as I can now without my notes recollect. On inquiry into the particulars &c., of the outbreak, I found them rather peculiar—viz., it was confined, almost, to two companies; when it began in the married lines, it spread from one to another of each family; in the hospital other patients not previously affected took it; and even the hospital servants, including a hospital assistant, got it apparently from patients suffering from it on whom they were, at the time of becoming ill, attending. It spread quickly through each lung, and from one lung to the other; there was scarcely ever a second stage, as the disease ran from the first stage quickly into the third, and into gangrene of the lungs. In most cases the nervous system was from the outset prostrated; the tongue dry, brown, and hard, there were sordes about the teeth, and in fact all the usual symptoms called "typhoid;" and there was in each case a "catching" pain in one or both sides—generally in a line under the axilla. I commenced by having the regiment removed from their barracks to tents; all persons affected with the disease were removed to a separate camp, where they were isolated from all others except their attendants; the attendants were forbidden from all communication with other persons or cases; and the barracks, married lines, &c., were thoroughly disinfected. Besides, everything was made ready for a march from the station should the outbreak not disappear with the above precautions. Soon after—almost at once—the above measures were taken the outbreak ceased, no new cases occurring, and within a fortnight there was not a case of the disease in the regiment. The 5th Punjaub Infantry at Abbotabad lost, I believe, sixty men from a similar outbreak; and although it was attributed to the sudden change from the warm climate of Dera Ghazi Khan to the cold and hilly climate of Abbotabad, I think that the cause was the same in both regiments —i.e., infection caught when marching through districts known to be affected with the cattle plague—pleuro-pneumonia—as met with in the year 1875 in the Punjaub and north-west frontier districts. The 1st Punjaub Infantry being chiefly "Pathans," had a great objection to post-mortem examinations, but I have had frequent opportunities in gaols under my charge on the north-west frontier of examining fatal cases of pleuro-pneumonia, and the appearances in the lungs were pretty uniform—viz., almost complete disorganisation of each lung with numerous and separate abscesses, and often gangrene of parts of the lung affected. Both lungs were usually involved, and there was a good deal of dirty soft lymph on the pleura of the affected lung, with a sanguineo-serous fluid in small quantities in the cavity of the pleura. The blood found in the left cavities of the heart was generally dark and thin.

In the type of pleuro-pneumonia just noted I found that the most successful treatment was that which in erysipelas is found most effectual—i.e. quinine, chlorate of potash, and tincture of the sesquichloride of iron, in fifteen-minim doses, along with, in this case, expectorants, antispasmodics, &c. Stimulants and good nourishment were given from the outset, and with success. In the ordinary form of pneumonia, as met with in our part of India, &c., I find quinine in small doses combined with Dover's powder (one to two grains) and ipecacuanha the best internal remedies to begin with, combined with sinapisms, followed up by "jacket" linseed-meal poultices. Good nourishment has to be given from the outset. Very soon it is generally necessary to give ammonia, squills, quinine, and compound tincture of camphor, instead of the Dover's powder, quinine, &c., above mentioned, and port wine or brandy has to be administered more or less freely, according to the tongue and pulse. I have never met with a case of pneumonia in Northern India which was benefited by bloodletting in any form, although I used to employ leeching and cupping in my earlier treatment, and so had then sufficient experience of the injurious and sometimes fatal effects of such treatment. As far as I have seen, the above remarks regarding the symptoms and treatment of pneumonia apply to Northern and Western Afghanistan, in both of which I have served, and as much to Europeans as to natives of the country, with this exception, that stimulants can with Europeans be begun earlier and have to be given more freely, as a rule, than with natives. A routine administration of either medicines or stimulants is, of course, to be deprecated in all cases, especially as it sometimes happens that wine or spirits, when given without attention to the pulse, increase the inflammation of the lung.

CASE OF TRAUMATIC TETANUS TREATED WITH CALABAR BEAN; RECOVERY.

BY C. CLARK BURMAN, L.R.C.P. & S. ED.

ON Sept. 8th last I was called to see a boy, eleven years of age, who had received an injury to his foot whilst driving a reaping machine. On examination of the case I found an extensive lacerated wound of the left heel; a large flap of skin and subcutaneous tissue was reflected over the os calcis, laying bare the posterior, and part of the inferior surface of that bone, but not injuring its periosteum. The tendo Achillis was laid bare for about two inches from its insertion to the os calcis. A considerable portion of the flap was missing upon its inner side, and its only connexion to the sole of the foot was by a narrow strip of skin, not more than half an inch in width. After cleansing the wound I replaced the flap, and retained it in position by means of sutures; but, as I feared would be the result, the upper and outer part sloughed—due, no doubt, to the small vascular supply through the narrow neck connecting it to the uninjured skin. Otherwise the wound was progressing favourably; the boy was in good spirits, and complained of no pain, except during the dressing of the wound. At first cold-water dressings were used, but so soon as sloughing took place carbolic-acid lotion was substituted. Upon Friday the 17th it seems that he complained to his mother of a "stiff neck," but of so slight a nature as not to be mentioned to me upon my visit next day. On Sunday the 19th he complained of stiffness of the jaws and difficulty in mastication, which on the following day had developed into well-marked trismus, the sterno-mastoid muscles upon each side being in a condition of tonic spasm. The risus sardonicus was distinct; the teeth could be separated only about half an inch; no general convulsions, however, had been noticed; there was great nervous excitability and slight epigastric pain. The pulse was 120 and hard, as if the arterial coats sympathised with the general muscular contraction. I at once prescribed chloral hydrate and belladonna in full doses, kept the room darkened and quiet, ordered him milk and strong beef-tea, with small but frequent quantities of port wine. An enema of castor oil and turpentine was administered. Upon Tuesday, the 21st, the first convulsion appeared, which was, however, neither severe nor of long duration. The pulse was still rapid and hard, but accompanied with very little feverishness. The wound was doing well, the slough separating nicely. During the two following days his condition was much the same, a general spasm occurring upon any sudden start or exertion, such as moving to have the wound dressed, &c. To relieve pains that he experienced along the upper part of his spine, he was laid upon his abdomen, with a pillow under his breast, and in this position he remained until convalescent. Ice not being readily obtainable, I ordered india-rubber bags filled with cold water (frequently changed) to be kept constantly applied to the lower cervical and upper dorsal regions.

Considerable difficulty now began to be experienced in swallowing the chloral and belladonna mixture, almost every attempt producing a convulsion, in which the body assumed the characteristic arched position, and all the muscles became quite rigid. He was able, however, to take considerable quantities of milk, also wine well diluted. I now administered morphia hypodermically, but the nervous excitability had now reached such a pitch that even to do this produced a convulsion. The jaws being now almost completely closed, and the difficulty and danger of administering remedies had become so much increased, that I obtained from Messrs. Savory and Moore a supply of their gelatine lamels, containing one-sixtieth of a grain of extract of Calabar bean in each; and on Wednesday, the 29th, I prescribed one every four hours, continuing the stimulants and as much milk and beef-tea as could be taken. The lamels were slipped in between the teeth and allowed to dissolve in the mouth. On Sunday, the 3rd October, decided symptoms of improvement showed themselves; the convulsions, which a few days before were so frequent and so easily excited—even the sudden falling of the door-latch was sufficient to induce one—were now less frequent and not so severe. The jaws could be opened to a slight extent, and the boy could retain and swallow his saliva. The general improvement continued until, on Thursday, the 7th, he was able to take a little boiled bread and milk, only one or two convulsions having occurred since the 3rd. The lamels were continued until October 10th, and since then his progress towards recovery has been steady and uninterrupted.

Throughout the whole progress of the case the state of the wound was all that could be desired; the slough having separated it was granulating nicely, no pain or uneasiness being experienced. On my last visit (Oct. 25th) he was sitting up, dressed, and able to get about with the assistance of a crutch, the only drawback being a little stiffness of the ankle from prolonged rest, which, however, readily gave way under passive motion; and a few days ago I had the satisfaction of seeing my patient walking about, looking little the worse for the severe illness he had gone through.

Whether the recovery of my patient was due to his youth, good health, and ability to take so much milk, beef-tea, &c. —thus keeping up his strength and enabling him to live out the disease, or to the use of the Calabar bean, or both combined—is, of course, a moot question, but the marked, immediate, steady improvement that took place after the administration of the Calabar bean would seem to indicate that that drug played a serviceable and important part in the treatment of the case, as also to show cause for a further trial of the Calabar bean (in the form of gelatine lamels) in similar cases.

I must speak a word of praise on behalf of the gelatine lamels. Their portability is evident, but I scarcely think their usefulness, under the circumstances as above described, is sufficiently appreciated. It is usual to administer remedies for tetanus hypodermically, but, as I have stated, this simple operation in my patient, whose nervous system was in so excited a condition, proved objectionable, on account of its bringing about a condition of tonic spasm, which it was sought to avoid or prevent. On the other hand, the administration of *fluid* remedies by the mouth, even when available, as in the early part of the disease, is not without similar dangers, inasmuch as in this case it proved so irritating that a choking fit, culminating in a general convulsion, almost always followed the attempt to swallow them; whereas the lamels, having been slipped between the closed teeth, were slowly dissolved and absorbed without causing any spasm.

Belford, Northumberland.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.—At the meeting of the Executive Committee, held on Wednesday last, Mr. T. Greenish, the President of the Pharmaceutical Society, Mr. James Cantlie, F.R.C.S., of Charing-cross Hospital, and Mr. Edmund Owen, F.R.C.S., of St. Mary's Hospital, were elected members of the committee. The guarantee fund has been increased by more than £100 in the last week, and Sir James Paget has placed his name upon the list of guarantors for £10 10s. The forms of applications for space are being prepared, and will be forwarded as soon as ready to those applying for them. No application for space will be considered unless received by the last day in March. Means are being taken to advertise the Exhibition in France, Germany, Austria, Italy, Russia, Scandinavia, Canada, the United States, India, and Australia.

EAST LONDON HOSPITAL FOR CHILDREN.

CASES OF CONGENITAL SYPHILIS.

(Under the care of Dr. FRANCIS WARNER.)

THE following cases illustrate the occurrence of temporary enlargement of the spleen and of laryngitis in syphilitic infants.

CASE 1. *Spleen enlarging under observation; desquamation of skin.*—Ada B——, aged nine weeks, was seen as an out-patient on June 4th, 1879, on account of a rash on the skin, and running from the eyes and nose. She had appeared healthy at birth. When five weeks old little red patches appeared first on the feet; the skin then turned white, and blisters formed and broke, and the feet had never been healthy since. Similar spots appeared on the face, and the rash gradually spread to the whole body. As the latest development of the skin disease, the nates had become very sore a fortnight previously.

When seen there was very marked desquamation of the hands and feet; the child snuffled, and there was a thick yellowish discharge from the nose; no thrush and no disease of the nails; no thickening of the long bones of the skull; voice in crying fair; spleen and liver not enlarged. Ordered twenty drops of solution of perchloride of mercury, with a little iodide of potassium, three times a day. A week later it was noticed that she looked better, the skin healing, with less desquamation.

On June 19th the sores on nates had healed; there was less desquamation. Spleen now felt distinctly enlarged, extending almost up to the umbilicus; the enlargement had occurred under observation. The child was stronger and better. There were no signs of rickets.

The skin condition continued to improve. The spleen was very distinct. On July 9th the spleen was subsiding; rash gone; no desquamation; still discharge from nose. On the 17th the spleen could not be felt enlarged; the child was getting fat. On Oct. 9th there were no visible signs of syphilis, and on Dec. 18th the child was healthy-looking, fat, and well.

CASE 2. *Child voiceless; laryngeal disease; death; necropsy; large spleen.*—Florence T——, aged seven weeks, was seen as an out-patient on Nov. 28th, 1878. When born there were "bladders full of water" about its head, but otherwise she appeared healthy. At three weeks old she had a sore mouth and face with thrush. When first seen the voice was fair; there was disease of the nail of the first finger of the left hand; it was dry, hard, and dead; the mother said there had been a little matter under it, but there was none seen. No other nail was thus affected.

On December 5th, on crying, the voice was lost, or almost lost. Much staining of the skin around the mouth, and on the nates and around the anus there were abrasions and dark-stained patches; no sores between the fingers and toes; thrush in mouth; spleen and liver appeared normal. It was found that soreness of the nates appeared with thrush when the child was three weeks old.

On the 17th there were fissures at angles of mouth and eyelids; the skin of forehead was desquamating; some desquamation of legs. Desquamation had occurred where there had been redness; thrush had gone. She was made an in-patient, and died Dec. 25th.

At the necropsy on Dec. 26th, brain, meninges, and skull were normal; the lungs were the seat of lobar and lobular pneumonia; the liver and kidneys were healthy; the spleen was large, and had recent lymph on its surface, causing soft adhesions; no other peritonitis. Larynx presented marked signs of disease, showing an ulcerated surface with a papillomatous appearance both above and below the ventricles; bronchi healthy.

The mother was under treatment for constitutional syphilis, with ulceration of the tongue and laryngitis.

CASE 3. *Voice hoarse; condylomata; ulcers on tonsils; nasal discharge.*—Henry G——, aged ten years, was first seen on Oct. 16th, 1879. His voice was hoarse; this was said to be recent. Around the anus were large condylomata with ulceration; these had appeared about three weeks previously. Ulceration of both tonsils had existed two months, and there had been discharge from the nose five months. The bowels were costive, and defecation was often attended with bleeding. There seemed no doubt that the boy was syphilitic, but on the other hand there was no proof that the syphilis was inherited, nor any suspicion that it was accidentally acquired. There was no keratitis, no ophthalmoscopic changes, no bone thickening, and no deformity of head or nose. On inspecting the throat there was seen superficial ulceration of either tonsil, spreading to the uvula and soft palate. From the nose there came an unhealthy glairy discharge, causing excoriation. Hoarseness of the voice was marked, and attended with marked stridor on deep inspiration. Ordered thirty drops of solution of perchloride of mercury, subsequently increased to sixty drops, with iodide of potassium, four times a day. The condylomata soon became drier; the tonsils, larynx, and nose remained diseased much longer. Tonsils were noted as healed on Nov. 13th. At that time an ulcer was seen over the right arytenoid cartilage. On Dec. 4th the ulcers on tonsils had healed; nostrils did not discharge; the latter symptom, however, returned. The condylomata healed up, but reappeared in January. Finally, by February the throat and nose appeared healthy, and the laryngoscope showed no ulcers, but the voice was still hoarse.

The patient was the youngest of eleven births:—1, never healthy, died at twenty-one years; 2, girl, died at twenty-four years, weakly; 3, girl, died at twenty-two years, weakly; 4, stillborn, healthy; 5, twins, one wasted, other stillborn; 6, stillborn at full term; 7, stillborn at full term; 8, miscarriage at fourth month; 9, stillborn at full term; 10, boy, aged twenty years; 11, patient. The patient was considered healthy at birth, and never had any sores on the skin till October, 1879. There was no history, sign, or probability of infection of syphilis.

CASE 4. *Spleen large, subsiding; slight rickets.*—Thomas D——, aged nine months, was seen as an out-patient June 12th, 1879. The mother said he had been healthy and well the first three weeks after birth, but not very fat. Then a rash came out on the nates, legs, and feet. "Blisters came out and bled"; these died away in a fortnight, and nothing more appeared till two months ago. There was thrush at the same time as the rash. Patient was the first child; there had been no miscarriage. The mother had some rash on her body while pregnant. When seen there was thrush; brownish mottling of the face, especially on forehead. In the right temporal region an oval patch, dark-brown, smooth and dry edges, slightly raised; a similar patch on chin. An abrasion, the size of a threepenny-piece, was seen at the side of the anus. There was moderate rickety condition, with "beading" of the ribs. Fingers and nails heathy; no bone thickening discovered. Spleen large, distinctly felt. Glands in both Scarpa's triangles enlarged. Ordered mercury ointment to be rubbed in.

On the 27th the ulcer near anus was not healed, and there was much discharge from nose. Voice good. Ordered twenty drops of solution of perchloride of mercury, with iodide of potassium, four times a day.

On July 10th two grains of mercury and chalk powder given four times a day. On the 24th the ulcers were healing. Spleen still large. Very little discharge from nose; not getting fat. On Aug. 14th no rash; the child appeared healthy and well; fat. Voice good; spleen subsiding. On Sept. 2nd the spleen could not be felt. No running at nose. On Jan. 5th, 1880, the child was well and fat and had no sores.

Remarks.—These cases illustrate the occurrence of temporary enlargement of the spleen, of chronic laryngitis in syphilitic infants. As to the splenic disease, in Case 1 the enlargement of the spleen occurred under observation, and lasted about one month. It appeared as the exanthem was passing off. In Case 2 the enlarged spleen was found on autopsy, and was covered with recent lymph. In Case 4 the spleen was enlarged during the exanthematous period, and subsided under observation. The child was slightly rickety, and this might be supposed to be the origin of the splenic enlargement, but that the subsidence was more rapid than occurs in rickets. With regard to the laryngitis, in Case 2 the child was voiceless, and the laryngeal disease was seen after death. In Case 3 ulceration of the larynx was seen with the laryngoscope.

ROYAL BERKS HOSPITAL, READING.

SIX CASES OF OVARIOTOMY.

(Under the care of Mr. O. C. MAURICE.)

FOR the following notes we are indebted to Mr. C. R. Graham, house-surgeon.

CASE 1. *Antiseptic ovariotomy; rapid recovery.*—Elizabeth F——, aged forty-five, married, was admitted on December 6th, 1877. She had been in the hospital on several occasions, suffering from menorrhagia, with some uterine enlargement, but had never been actually incapacitated from following her household duties.

On admission she had a considerable tumour in the abdomen. There was fluctuation as well as dulness on percussion over the upper part of the abdomen, but the flanks were distinctly resonant. Measurements indicated an ovarian tumour. In order to verify the diagnosis the aspirator was used, and a small quantity of fluid drawn off.

On Dec. 23rd ovariotomy was performed antiseptically, the pedicle being ligatured. The case progressed so favourably that the patient was convalescent at the end of three weeks, and was discharged cured thirty days after the operation. The temperature on the morning of the 25th Dec. was normal, but rose to 102·2° in the evening, after which it gradually descended to normal. The pulse only once reached 105, that also being on the second day after the operation; it afterwards did not exceed 90.

CASE 2. *Antiseptic ovariotomy; recovery.*—Jane W——, aged forty-two, was admitted on Dec. 31st, 1878. She was married, and had had eight children, the youngest being born in February, 1876. The catamenia had been quite regular up to the time of admission. In February, 1878, she noticed a swelling on the left side about the size of an orange; it gradually got larger, but was not accompanied by much pain. Six months before admission ascites appeared, and continued to increase, giving rise to dyspnœa and great distress.

On Jan. 10th, 1879, paracentesis abdominis was performed, and nineteen pints and a half of ascitic fluid were drawn off, to the great relief of the patient. A hard, globular mass, about the size of the fœtal head, freely movable, could then easily be felt in the left lumbar region. An ovarian tumour was diagnosed, and on Jan. 23rd ovariotomy was performed under the spray. An incision four inches long was made in the mesial line. There were no adhesions; the cyst, which was multilocular, was tapped, and a small quantity of clear fluid and gelatinous matter were drawn off. The pedicle was secured by an ordinary double ligature, cut short, and returned into the cavity of the abdomen. The wound was brought together by deep silk and superficial wire sutures, and dressed with lint soaked in carbolic oil. Strapping, pads, and a binder completed the dressings.

On the 28th the dressings were removed, the wound looking well. Temperature 100°.

Two days later the four deep sutures were removed. A drop of pus escaped on taking out the lower one. Carbolic oil dressings were discontinued, the wound being simply strapped together with adhesive plaster and covered with oakum. Temperature 100·2°.

On Feb. 3rd the wound was dressed. With the exception of about half an inch at the lower part it was quite healed. Temperature 99·2°.

From this time the patient made a good recovery, although convalescence was somewhat delayed owing to the patient getting a small bedsore. She was discharged on April 1st.

CASE 3. *Dermoid cyst of ovary; ovariotomy; death.*—Jane P——, aged fifteen, was admitted on April 22nd, 1879. She gave the following history. About Christmas, 1878, she noticed a swelling on the left side of the abdomen, which gradually enlarged. It was occasionally painful. She admitted having had undue familiarity with her cousin, a lad of seventeen, six months before. On admission the tumour was irregular in outline, solid, and situated in the lower part of the abdomen, extending upwards as far as the umbilicus; it had a slight inclination to the left side, and was freely movable. On examination per vaginam a number of small hard tubercles could be felt through the posterior wall of the vagina; the os uteri was high up behind the pubes. On introducing the finger into the rectum it at once came into contact with a hard globular mass, resembling very much the fœtal head, there being also a well-marked suture. No material change took place in the patient's condition until May 16th, when morning sickness came on and lasted ten days. A diagnosis was a matter of considerable difficulty, as owing to the previous history of the case and condition of the parts pregnancy was very strongly suspected, but after some time had elapsed and none of the other signs of pregnancy made their appearance the case was considered to be one of ovarian growth, probably of a dermoid character. As the patient's health began to fail, it was deemed advisable to make an exploratory incision, and to be guided by circumstances.

On April 28th an incision two inches in length was made in the linea alba, and an ovarian tumour discovered. There were no adhesions, the pedicle was ligatured, and hæmorrhage, which gave some trouble, having been arrested, the wound was closed with carbolised silk sutures and then strapped with adhesive plaster. In the evening the temperature was 102·6°; pulse 140. The bowels acted. On the 30th she vomited. Temperature 98·6°; pulse 128. On May 2nd the pulse was very weak, 128; temperature 103°. Tongue dry and coated with a brown fur. Two grains of quinine were given every four hours and two teaspoonfuls of brandy every two hours. The wound was dressed. Next day when the wound was dressed the sutures were removed. The pulse was counted with difficulty, about 160 per minute. Patient had been sick twice. She gradually sank and died on June 4th. The post-mortem revealed diffuse peritonitis, the whole of the abdominal organs being matted together.

The growth was a characteristic dermoid cyst, consisting of bone, cartilage, &c. It sprang from the right ovary, was multiple, the smaller cysts containing a thick gelatinous fluid. The inner surface of the cyst was made very uneven by being scattered over with circumscribed elevations, and there were also several tufts of hair two or three inches in length, of a fair colour, contained in the cyst. The bones resembled those of the fœtal skull, being in some places nodular, others laminar, and presenting a well-marked suture. In places the cyst wall was composed of cartilage.

CASE 4. *Antiseptic ovariotomy; recovery.*—Eliza R——, a domestic servant, aged twenty-five, single, was admitted Aug. 26th, 1879. She had felt out of health all the summer, but was able to continue her work up to three weeks before, when she noticed a swelling at the lower part of her abdomen in the median line; this had rapidly enlarged, but was not painful. Sickness had occasionally occurred in an evening. She menstruated quite regularly up to two months before admission.

On Sept. 9th the tumour extended one inch above the umbilicus, and the circumference of the abdomen (opposite the umbilicus) was 32 in., but by Oct. 3rd this had increased to 33½ in.

On Oct. 17th ovariotomy was performed antiseptically. An incision four inches in length was made. The cyst was unilocular, and contained a large quantity of fluid of a purulent character. The pedicle was ligatured as in the previous cases. In the evening nausea and vomiting came on, and lasted until the following day; they were arrested on the administration of beef-tea enemata. The urine also became of a dark greenish colour, due to the absorption of carbolic acid from the dressings, and continued so for several days.

On the fifth day (Oct. 22nd) the dressings were removed, and it was found that, with the exception of a quarter of an inch at the upper part of the incision, the wound was quite healed. The sutures were taken out, and from this time the patient made an excellent recovery. She attended service in the hospital chapel on Nov. 2nd, and was discharged well Dec. 2nd, 1879.

Remarks.—Owing to the tumour beginning in the median line, the lubricated state of the vagina, and the soft and patulous condition of the os, there was at first some difficulty in diagnosing this case from pregnancy. Before the operation adhesions were expected to be found. As the patient appeared to suffer several slight attacks of peritonitis fortunately these expectations were not realised. The highest temperature registered after the operation was 99·6°, and the pulse never exceeded 98.

CASE 5. *Antiseptic ovariotomy; recovery.*—Susan H——, a barmaid, single and aged nineteen, was admitted Dec. 9th, 1879. She had previously (in 1877) been in the hospital for an abdominal swelling, when fluctuation was detected over the whole of the abdomen. An ovarian tumour was diagnosed, and she was tapped; but, owing to her fainting, only fifteen ounces of fluid were drawn off. During the next few days she passed an unusually large quantity of urine, and in a week the abdomen had returned to its normal size, leaving only a slight thickening in the left iliac region. The fluid removed was quite clear, not coagulable by heat or nitric acid; sp. gr. 1003, with a slight deposit on standing of epithelial cells and crystals of phosphate of lime.

The enlargement having reappeared it was decided to operate, and on December 12th ovariotomy was performed antiseptically. Twenty-three pints and a half of serous fluid were drawn off; sp. gr. 1010, slightly alkaline, and containing a small quantity of albumen. The cyst was unilocular, and sprang from the broad ligament on the left side. The pedicle was secured with a triple ligature. On the following day the temperature rose to 100·4°, but afterwards never reached more than 99·6°. The patient recovered without a bad symptom, and was discharged Jan. 6th, 1880.

CASE 6. *Antiseptic ovariotomy; recovery.*—Lucy A——, aged twenty-seven, single, had suffered from abdominal pains for three years. Eighteen months before admission she noticed a tumour in the right pelvic region. It had grown rapidly and become more painful during the last few months. She was admitted on August 17th, 1880, and on the 28th ovariotomy was performed antiseptically. The cyst was unilocular, and the pedicle was ligatured as in the previous cases. There was a large number of adhesions; posteriorly several coils of intestine were firmly attached to the cyst, whilst inferiorly it was bound down to the fundus of the uterus by a band of fibrous tissue, an inch broad and half an inch in thickness. The patient progressed very favourably, though her recovery was somewhat delayed owing to cystitis being set up by passing the catheter. Both pulse and temperature kept rather high for three weeks, the former varying between 100 and 132, the latter between 99° and 101°, but on the evenings of the tenth and seventeenth days after the operation the temperature reached 102°, it then came down to 99°, when it remained stationary for a time, after which it became normal.

The patient was discharged cured Oct. 25th.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Observations on the Value of Stethometry in the Prognosis of Chest Disease.

THE ordinary meeting of this Society was held on the 25th inst., J. E. Erichsen, Esq., F.R.S., President, in the chair. There was but a scanty attendance. Only one paper was read, which was a further contribution to "stethometry," by Dr. Ransome, detailing with great care the result of numerous observations made by him on the movements of the chest in pulmonary disease.

The following is an abstract of the paper, entitled "Further Observations on the Value of Stethometry in the Prognosis of Chest Disease," by ARTHUR RANSOME, M.D. The bearing of stethometry upon the prognosis of chronic bronchitis, asthma, emphysema, and pleurisy having been pointed out, this paper then deals more closely with the records of chest measurements of 102 persons affected with various forms of phthisis. Fifty of these cases were either chronic, or persons in whom the disease had become quiescent (twenty-five males and twenty-five females). Forty of these were acute (twenty males and twenty females), and twelve of them were exceptional cases, in whom the chest measurements could not be relied upon from their youth, and who had succumbed from accidental causes, such as hæmorrhage, &c. The points selected for the application of the stethometer were the middle points of the clavicles and the anterior ends of the third ribs, the movements measured being chiefly those in the (horizontally) forward and the (vertically) upward directions. In all cases the measurements were obtained in an interval of comparative quiescence of the disease, and cases complicated with extensive pleuritic adhesions were excluded from the tables. From these records it appears that—1. The respiratory movements are much smaller in acute than in chronic cases. In six of the acute cases no movement was perceptible in one or another of the directions of motion at one of the points examined. No such immobility was found in any of the chronic cases. The average forward push of the clavicle in acute cases, on the worse side, was 0·15 in., in chronic cases 0·29 in. This movement over the third ribs was on the average 0·25 in. in acute cases, and 0·54 in. in chronic cases. A similar contrast was remarked in the extent of the *upward* movements. The average upward movements of the clavicles in the male acute cases was 0·25 in. on the worse, and 0·30 in. on the better side; in females 0·26 in. and 0·38 in. respectively. In the chronic male cases the corresponding diminutions were 0·50 in. on both sides; in females 0·56 in. on the worse and 0·66 in. on the better side. The third ribs move upwards in acute male cases 0·36 in. on the worse, and 0·45 in. on the better side. In females the numbers are 0·38 in. on the worse, and 0·51 in. on the better side. In chronic cases these dimensions are for males 0·72 in. and 0·74 in.; for females 0·78 in. and 0·85 in. 2. There are certain peculiarities of chest movement in chronic and acute cases, arising out of the power of independent rib movements. This is shown (*a*) in the extreme restriction of motion of parts placed over an advancing softening of the lung in its comparative freedom over a quiescent vomica. The third stage of phthisis had been reached in thirty-three cases—twenty-one of the acute, and twelve of the chronic series. The average forward push of the clavicle in the chronic cases was more than double that in the acute series, and in half the former group there was actually a larger extent of motion over the site of a vomica than on the less affected side of the chest. The circumstance was not observed in any of the acute series. The third ribs show nearly three times the amount of forward movement in chronic than in acute cases, and in the former group the motion of the bone over the excavated lung exceeds that of the opposite side. (*b*) Efforts at compensation are made, by both clavicles and third ribs, in either an upward or a forward movement. When these efforts take place in the upward direction they must be regarded either as an unfavourable sign, or else as only a measure of the muscular power that the patient can bring to bear on the obstruction to healthy breathing. There were sixteen such cases of exaggerated upward movements amongst the chronic series, and six in the acute series. In the forward direction the effort at compensation has a distinctly favourable significance—it occurs fifteen times amongst the chronic cases and only twice doubtfully amongst the acute group. Much assistance may also be derived from repeated measurements of the same case, and instances are given of the kind of information thus obtainable. From the data afforded in this paper it was concluded—1. That a small amount of movement of the chest, especially in the forward direction, is of evil augury; and that when, in adults under forty, the forward push of the third rib is less than 0·35 in., there is reason to foretell a rapid course of the disease. 2. That we may usually give a favourable prognosis when in an adult there exists an inactive vomica, with a considerable extent of movement in the ribs overlying it; and the sign is still more favourable when the forward motion of the bone is greater than that of the corresponding point on the opposite side. 3. That an excessive or compensatory effort at *upward* movement tells us little as to the gravity of the disease, but a free compensatory *forward* movement is a favourable sign. 4. That stethometry must be regarded as only one of the elements of prognosis.—The PRESIDENT, in according the usual vote of thanks, remarked that the paper was one which required careful perusal, and that the author had extended into the domain of prognosis the precision with which pulmonary affections were now diagnosed.—Dr. BROADBENT said the value of the stethometer was that it directed attention to given points in chest disease, which might otherwise be passed by as of little importance. It would be of value if it did nothing more than help to form a prognosis in the early stages of disease, for it pointed out more accurately than the eye or hand the limitation of movements of the chest in such conditions. One point came clearly out—viz., that the greater comparative extent of upward movement was often compensatory for defective forward movement. All must recognise the scrupulous care with which Dr. Ransome had made his observations and laid the points of his paper before the Society, realising more fully than had been done before the aid obtainable by definite and precise measurement of thoracic movements.—Dr. **Douglas Powell** said that all must be grateful for any aid in the prognosis of consumption, the peculiarly intermittent character of which rendered prognosis so difficult. These observations, which required so much skill and patience, especially when the difficulty of obtaining trustworthy records of the movements of the chest is considered, would be of great value for reference and guides to others—like the researches of Dr. Hutchinson with the spirometer. Dr. Powell had found the most valuable indication of the respiratory power in phthisis to be the power of expiration rather than that of inspiration; noting, that is, the degree to which the patient can empty the chest of residual air. The author's observations were also of value in correcting previous notions—e.g., the localised diminution of movement was generally regarded as evidence of chronic disease, but Dr. Ransome had shown that the movement was more impaired in acute than in chronic phthisis—in other words, that fixity was a sign of activity of progress of the disease, mobility of chronicity. Of course, in the stage of consolidation the movement in an acute case is limited; but when softening takes place the movement is generally freer; whilst if the disease become arrested, the walls flatten and movement is diminished.

The Society then adjourned.

MEDICAL SOCIETY OF LONDON.

Treatment of Nævi and other diseases by Ethylate of Sodium.

At the meeting of this Society on the 17th inst., F. J. Gant, Esq., President, in the chair—

Dr. **John Brunton** exhibited a case of Nævus of the Scalp, successfully treated by sodium ethylate, and also showed a case in which some nævoid spots on the face had been similarly dealt with.—Mr. **Wordsworth** declared that in many cases nævi spontaneously degenerated and disappeared—even after temporary increase—rendering operative measures unnecessary. But where they occupied situations liable to produce deformity, and when they were very large, they should be destroyed. On the eyelids they should be dealt with early, to avoid visible scars and contraction; several punctures with the cautery needle into the nævus itself being sufficient.—Mr. **Spencer Watson** had used sodium ethylate, but was not satisfied with the result, except for superficial nævi.—Mr. **Edmund Owen** also said that he had given it an extensive trial, and found it answer well in small superficial cases, but it had failed for deeper growths, which he had finally to treat with Paquelin's thermo-cautery. For small nævi almost any method availed, even the friction of clothing sufficed for their obliteration. The case exhibited by Dr. Brunton had been one year under treatment, and had required twelve applications of the caustic. The thermo-cautery had the advantages of rapidity of action and certainty.—Mr. **Royes Bell** had also failed to get good results from sodium ethylate in larger nævi. He agreed with Mr. Wordsworth as to the advantages of leaving many of these cases to spontaneous cure. The length of time occupied in the treatment by the ethylate was an objection to its use.

Dr. **Richardson** then read a paper "On Ethylate of Sodium in the Treatment of Nævus and other forms of Disease," the text of which will be found at p. 168.

Dr. **Routh** thought that the injection of this agent would prove useful in uterine and other fibroids. He had seen, especially in mammary tumours, marked benefit from injection of iodine, but the procedure was always followed by severe inflammation. He asked if there was much inflammation in the case of goitre treated by Dr. Richardson.—Mr. **Owen** would like to hear from Dr. Richardson the exact and probable effect which would follow upon the solution being injected into the interior of a good-sized vessel in the thyroid gland. Would it, like the ferric solution, cause coagulation? If so, he would regard its use subcutaneously with the gravest apprehension. Looking to the effect which the ethylate had upon solid tissues, he should infer that its effect on the blood would be considerable, and its injection might not improbably be followed by thrombosis or secondary hæmorrhage. — Dr. **Woakes** thought the treatment promised to afford a new departure in the case of goitre, in which the methods ordinarily in vogue were more or less abortive. Apprehensions of danger from injecting fluids into solid organs were groundless. It was a daily practice at the Throat Hospital to inject goitrous tumours chiefly with tincture of iodine, and he was not aware of a single mishap accruing beyond an occasional superficial abscess caused by the escape of a portion of the fluid into the subcutaneous areolar tissue. Injection of hypertrophied lymphatic glands, with dilute acetic acid, was common, and the results most favourable. All the accidents seemed to have occurred with the injection of perchloride of iron; but this, diluted, was constantly used in the treatment of cystic goitre, the cyst being first emptied through a cannula, the injection taking place into the cyst cavity, which in a few hours became a suppurating surface. Probably tannin in solution would supersede the use of iron for this purpose, though, with the observance of proper precautions, the injection into such structures would prove to be a perfectly safe procedure; and on this ground it seemed probable that Dr. Richardson's suggestion would prove a valuable one.—Dr. **Crocker** referred to a case of death from abscess due to injection of perchloride of iron into a thyroid tumour.—Mr. **McHardy** also alluded to a case of cystic goitre, in which death resulted from a like injection.—Dr. **Brunton**, in reply, said that he had applied the agent about twelve times in the case of the child. He used a glass-rod, applying the ethylate whenever the crust was removed easily. He considered the remedy to act in a threefold manner—as a caustic, an astringent, and as a coagulator.—Dr. **Richardson**, in reply, said that he did not advise the hypodermic injection of ethylate of sodium, except in cases of extreme danger to life, and when other means had failed. It undoubtedly dissolved gland structures, and the addition of alcohol increased its coagulating effect. Nævi treated subcutaneously had not been so successful in result as when the agent was applied externally.

CAMBRIDGE MEDICAL SOCIETY.

Treatment of large Hydatid Cyst of Liver.

A meeting of this Society was held on Friday, January 7th, Professor Paget, M.D., F.R.S., in the chair.

Dr. **Grove** (St. Ives) gave an account of the Treatment by Aspiration and by Drainage of an unusually large Hydatid Cyst of the Liver. The patient was an unmarried woman, aged thirty-five, who had had symptoms for two years referable to the liver. When first seen on May 26th, 1880, the patient was suffering from acute pain in the right hypochondrium, where there was an increase in size. The pain and tenderness becoming more severe, she was seen by Dr. Latham in consultation. At this date (June 17th) the liver was found to extend as low as the crest of the ilium, it was hard and resistant, except just at the margin of the ribs, about two and a half inches from the median line, where there was a feeling of elasticity; on pressing at that point, and between the fourth and fifth intercostal spaces, there was a suspicion of fluctuation. Dulness on percussion from the lower margin of the third rib down to the level of the crest of the ilium, except over an area of about two inches in diameter (corresponding to the fourth, fifth, and sixth costal cartilages), which was distinctly tympanitic. The respiratory sounds were heard well only under the clavicle. Posteriorly a tympanitic note at lower angle of scapula and from that to the spine; normal resonance above that, and absolute dulness below. Over this posterior tympanitic area the respiratory sounds were feeble, and there was marked tremulous bronchophony. The patient, during the examination, felt much pain, especially at the tip of the right shoulder-blade, the whole right side being extremely sensitive. As she had occasionally profuse perspirations, this, with the other signs, made it not improbable that there was a suppurating hydatid cyst in the upper portion of the liver; but as the sense of fluctuation was very slight, it was considered advisable to wait a few days before proceeding to operative interference. To continue to take effervescing mixture and anodyne draughts. On June 21st the general condition was worse and the girth had increased four inches (to thirty-four inches). There was now an elastic distinctly fluctuating tumour to be felt below the margin of the ribs. In consultation with Dr. Latham it was resolved to perform paracentesis. The puncture was made two inches to the right of the middle line and one inch below the costal cartilages; evacuation of nine pints and a half (imperial) of offensive semi-purulent fluid, containing numerous empty cysts. The operation was performed with the aspirator with a full-sized needle and occupied upwards of an hour. In the course of the following days there was some diarrhœa, the stools being of pale colour. On July 9th (evening) a rise of temperature was noted, with dry tongue and little appetite. The girth had again gone up to thirty-two inches, and was daily increasing; pain and oppressed breathing. On July 14th aspiration was again performed; seven pints and a half of bile-stained fluid were removed. Next day potassa fusa was applied somewhat to the right of the puncture to form an issue. The motions were devoid of bile. On the 18th the cyst was tapped through the eschar with trocar and cannula, the fluid removed being very biliary. Cavity washed out with chloride of zinc solution. An india-rubber drainage-tube nine inches long was introduced through the cannula, the latter was then withdrawn and the tube retained. The cyst was washed out twice daily with 2 per cent. of carbolic solution; the discharges were deeply stained with bile; entire absence of bile in the stools. For several days from July 21st the patient became weaker, emaciated, with sickness and diarrhœa. Bile began to reappear in the stools, and for two weeks from August 1st there was a great improvement, the chief trouble being constipation, which was relieved by enemata. On August 14th Dr. Grove was called up, and found the patient suffering severe pain in abdomen, with furred tongue and loss of appetite; large flow of bile from cyst. The cyst had contracted considerably, and on August 20th it contained only one syringeful. The stools became natural, and she continued to improve until, about the middle of September, the tube, which had been shortened from time to time to about three inches, was removed; granulations had all but closed the orifice, and the wound was allowed to heal.—Dr. LATHAM, who had seen the case in consultation, remarked on the rapidity with which the cyst had enlarged, both in the first instance and after the fluid had been once removed. There was tympanitic resonance over the fifth, sixth, and seventh costal cartilages, and, on auscultation, distinct tremulous bronchophony. There was a certain amount of air in the cyst; and, at the second puncturing, there was a great rush of air. He had once before observed tremulous bronchophony where the fluid was not in the pleural cavity. The largest-sized aspirating needle was used, but even that became immediately blocked by the cysts, and it had to be cleared many times in the course of the operation. The amount of fluid removed on the two occasions was 340 oz., an unusually large, if not unprecedented amount. The discharge by the drainage-tube was almost pure bile, and it was probable that the destructive changes in the cyst had opened a communication with one of the larger bile-ducts.

(To be concluded.)

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

A MEETING of the members of this association was held at Wakefield on Wednesday, Jan. 19th. The members of the association assembled at the Town Hall, and then proceeded to visit the Infectious Diseases Hospital recently erected by the Corporation of Wakefield, near Park Hills, and the West Riding Pauper Lunatic Asylum, where they were courteously received by Dr. Major, the medical superintendent. In the afternoon, a general meeting of the members was held in one of the committee-rooms of the new Town Hall. The proceedings, which occupied two hours, were of an interesting character. Mr. S. W. North, of York, the medical officer of health for that city, and the president of the association, occupied the chair, and there were also present the following gentlemen:—Mr. B. Kemp (Horbury), F. H. Wood (Wakefield), Mr. Wade, Dr. Scott (Ilkley), Dr. Farquhar (Pudsey), Dr. Hime (Sheffield), Dr. Butterfield (Bradford), and one of the Commissioners appointed to inquire into "the woolsorters' disease," Mr. J. Mitchell Wilson (Doncaster), secretary to the association, and Ald. Sellars, and Councillors Flower, Tattersall, and Sherwood, of Wakefield.—The PRESIDENT, in opening the proceedings, alluded to the great interest which is being taken at the present moment in regard to the prevention of infectious diseases. Referring to infant mortality, the President said that a very large number of deaths had taken place from diarrhœa and other causes, and arrangements were being made for a conference of medical officers of health to be held at Leeds or York in April to discuss the matter. The President also remarked that Dr. Barry, the late secretary to the association, had been appointed medical officer for the island of Cyprus, and during the meeting was elected an honorary member of the association.—Dr. WADE, the medical officer of health for Wakefield, then read a paper on the Sanitary Condition of Wakefield during the last Ten Years, and it was followed by an interesting discussion, in which the President and Dr. Butterfield (Bradford), Dr. Farquhar (Pudsey), Dr. Hime (Sheffield), and Dr. Wilson (Doncaster), took part. The last-named gentleman, in referring to a suggestion that schools should be closed as one means of preventing the spread of infectious diseases, said that this was a question in which teachers were greatly interested, because, if children were not permitted to attend school regularly, teachers lost a portion of the Government grant. He therefore thought that the matter was one which ought to be laid clearly before the Education Department. — Mr. BUTTERFIELD mentioned that a serious outbreak of scarlet fever had been caused at Bradford by two children who had had a mild atttack of it going to school before they had thoroughly recovered, and by other children in the school amusing themselves by picking the skin off the fingers of the children who had been infected. Mr. Butterfield then read some lengthy notes on "Woolsorters' Disease;" but as he and his fellow commissioners have not yet completed their inquiry, the representatives of the press were requested not to give publicity to the contents of his paper at present. Mr. Butterfield having replied to a few questions by Dr. Hime of Sheffield, the last-named gentleman exhibited a cheap and simple apparatus for testing the quality of milk.—A vote of thanks was given to the Mayor and Corporation for the use of the Town Hall, and subsequently some of the members dined together at the Bull Hotel.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

AT the fourth meeting of this Society, held on the 7th inst. at the Royal Kent Dispensary, Greenwich, Dr. Purvis in the chair, the following resolution was proposed by Dr. Purvis, and seconded by Mr. W. Lockhart, F.R.C.S.E., and carried unanimously:—"That the members of the West Kent Medico-Chirurgical Society tender to Dr. Habershon and Mr. Cooper Forster their cordial sympathy in the circumstances that have led to their resignation of the offices at Guy's Hospital, which they have so long filled with distinction and usefulness."

Dr. Galabin, Assistant Obstetrical Physician to Guy's Hospital, then read a paper on "Some cases of Tumours of the Abdomen simulating Ovarian Tumours." Dr. Galabin gave the details of several such cases which had come under his notice, which showed how very difficult it is to distinguish between such tumours, as several cases which were considered by himself and others to be ovarian, proved to be otherwise when operated on.

Reviews and Notices of Books.

Peruvian Bark: a Popular Account of the Introduction of the Chinchona Cultivation into British India. By CLEMENTS R. MARKHAM, C.B., F.R.S. London: Murray. 1880.

TO introduce into one country the cultivation of a plant which is a native of another might seem a problem of the simplest practical character; but how complex and difficult the task may be, what energy and perseverance are necessary to overcome its difficulties, is well known to the few who are familiar with the history of the introduction of the cinchona plant into India. To those who are not, we commend the story as told in this not too prolix volume of 500 pages, by Mr. Clements Markham, to whose labours the achievement is almost entirely due.

As the work is intended for popular perusal, Mr. Markham begins with a sketch of the history of the Peruvian bark. He describes what many of our readers already know, the origin of the name from the lady who, first of Europeans, owed to the bark her recovery from fever—a lady who had entertained our own Prince Charles and Duke of Buckingham, and the ruins of whose castle at Chinchon still stand at the village of the same name, not far from Madrid. The omission by Linnæus of the first *h* in her name, when he designated the plant after her, is regretted by Mr. Markham and by others, as obscuring its origin, but the Linnæan orthography is now stereotyped by almost universal custom, on which our own endeavour, for some years past, to influence by example, has had no effect. "Quina," it is hardly necessary to say, has nothing to do with the name of the plant, being only the Peruvian name for bark.

The story, from the first discovery of the value of the bark to its latest transplantation, is a long and interesting one, marked by incidents of social interest and personal adventure, by many an instance of self-sacrifice and heroism, and also by many an example of rapacity, injustice, and stupidity. Religion and science each had its share in assistance or obstruction; the use of the bark was condemned by Protestants because it was brought from Peru by Jesuits, and the discovery of the actual plant from which the bark came was an indirect result of an attempt to ascertain the shape of the earth.

Mr. Markham describes at length the natural history of the several species of cinchona, and the particulars of the discovery and geographical habitat of each of the five groups of valuable forms—Loxa, and its "crown" barks; the western slopes of Chimborazo, and their red barks; the Colombian region; Northern Peru, where the "grey bark" grows; Southern Peru and Bolivia, with their precious Calisaya bark. When the value of the bark became recognised, the supply was in time threatened with extinction. The cinchona-gatherers destroyed the trees in getting the bark; they simply stripped it from them, and the barkless trees quickly died, root and all. In some instances, relying on the abundance of the supply, after a tree was cut down they did not even take the trouble to remove the bark from the under-side of the trunk. Hence in time every cinchona plant was destroyed for ten or twelve days' journey from villages which were once surrounded by them.

The need for quinine in India, the remoteness of the South American source, and the similarity of the climate of many parts of India to that of the cinchona regions of South America, led to a suggestion for its introduction of being made as long ago as 1839 by an honoured member of our profession, Dr. Royle. Twenty years were to pass, however, before steps were taken to carry out the suggestion. The Dutch were before us in enterprise, for in 1853 they introduced the plant into Java. But the undertaking was ill-planned. The varieties chosen turned out to be of little value; and one, which, being the most hardy, was chiefly cultivated, was found to be of no value at all. Dr. Royle renewed his attempts to get the Government to take some steps with regard to India, but died in 1857, unsuccessful. His words, however, lived after him; and in 1859 Mr. Markham, who had travelled much, for geographical survey, in the cinchona forests of Peru, resolved, at the request of the India Office, to devote himself to the work. It could not have fallen into better hands. With his special qualifications for the difficult task, Mr. Markham evidently unites great personal energy and organising power. It was resolved to apply to the Government to carry out the work, but the help thus afforded was scarcely efficient. It was decided that five expeditions should be despatched, one to each of the regions in which the valuable bark grows, since it was doubtful which species would best bear cultivation in India with least loss of its valuable properties. The most difficult of these expeditions, that into the forests of Caravaya, in which the Calisaya bark grows, was undertaken by Mr. Markham himself. The narrative of his journey, given in detail, is full of vivid interest. The journey from the small coast town on the Pacific coast had to be performed on mules, along for the most part unfrequented paths. They started from Islay on March 6th, 1860, and it was not until May 1st that the mountain forests were reached. Many of the roads were at their best like "back-attic stairs after an earthquake," while swollen rivers added to the difficulties and even peril of the journey. When they reached the cinchona districts, 5000 feet above the level of the sea, they had to penetrate into dense tropical forests, where no European had ever been before, and search long before they found the plants. Having succeeded in securing the needed specimens and commenced their return journey they found that their perils were not yet over. The people of the district had been excited by rumours that the export of the plants would ruin their bark trade, and were resolved that not a single plant should be carried away. It was necessary to avoid all towns and villages and to shape a direct compass course across the Cordilleras. In their journeys they were only saved from starvation by an occasional meeting with a friendly Indian, but ultimately reached the coast in safety. The other expeditions were equally successful. One of the most important of these was the search for the red bark by Dr. Spruce, to whose scientific character, energy, and perseverance Mr. Markham pays a high tribute. By the efforts of Messrs. Ledger and Cross in the other expeditions all difficulties were overcome in the end. Plants and seeds of all the cinchona species known to commerce were brought to the coast, and the plants satisfactorily established in Wardian cases. In a sad chapter Mr. Markham tells a very dark story of the insufficient recompense to those who, at the risk of life, and, in several instances, at the loss of health, effected this work. The original agreements were for comparatively small remuneration, so that, if the attempts were unsuccessful, little money loss should be incurred by the Government, the generosity of which was trusted to, should success reward the attempts—a trust ill-placed in every instance.

The selection of the most appropriate sites in India for the cinchona cultivation required much care. They were chosen under Mr. Markham's own supervision, guided by his experience and observation in South America. The first and most important plantation was in the well-known Nilgiri Hills, the most delightful climate in the world, where "the warmth is not heat, and the coolness is not cold"; and the plantation was successfully carried out by Mr. McIvor, the Superintendent of the Government Gardens at Utakamund. The experiments and results here and elsewhere are graphically narrated by Mr. Markham. By 1866 there were 244,871 trees permanently planted out. "The old jungle had disappeared, and in its place were the rows of Peruvian bark trees with their graceful and beautiful foliage." Numerous private plantations have since sprung up; no less than 290,000 cinchona plants and 503 ounces of seed having been given to the public up to 1875. A very important and promising discovery was made in 1873—that of a spontaneous hybrid, which contained three times as much alkaloid as the ordinary species.

The other cinchona plantations of India are next described, especially in British Sikkim and Ceylon. The climate of the latter is well adapted for the purpose, and the extent of cultivation and amount of labour promised a fair trial. So rapidly has the cultivation spread that in 1877 there were no less than 5578 acres under cultivation, and the number of trees now planted out is about seven millions. The entire cultivation in Ceylon is now carried out by private companies and private proprietors; Government having, so far, only given its attention to the propagation, nursing, and classification of the plants.

The introduction of the cinchona plantation into India has been a financial success. The amount of quinine needed in India is very large, the yearly demand being about 10,000 lb., and the cost nearly £40,000. The total cost of the introduction and growth of the cinchona in India up to 1876 was £129,628, and by 1880 the whole capital amount had been paid off, and the plantations had begun to yield a clear annual profit. But this is not all. One of the objects urged from the first by Mr. Markham, and which has been partly attained, was the preparation of a cheap febrifuge for the use of the poor, and it has led to the manufacture of a similar febrifuge in Europe, and thus promises to be of immense benefit to the civilised world.

The East India barks have even entered the London market, and the position they take there is a very high one. In 1878–9 the Government bark sales showed a profit of £35,293. In 1879–80 the total yield of Peruvian bark from India and Ceylon was 1,172,000 lb., and it is now second in point of quantity only to Colombia, which exports six millions. But as regards quality the East Indian supply stands first; and some specimens have attained a higher price than has ever been reached by South American specimens. It is very depressing to learn that, in spite of this success, and promise of still greater success, the Government plantations have been neglected, and future prospects have been jeopardised, to secure large present results. This is the case chiefly in the Nilgiri plantations since the death of Mr. McIvor. In Sikkim more enlightened views have prevailed, and the true object of the cinchona plantation is understood and appreciated. It is probable that, under due management and fiscal regulation, the enterprise may in time come to be of vast financial importance to the Indian Empire. A writer in the *Pall Mall Gazette* of Sept. 18th, 1880, points out that it is probable that China will hereafter be among the largest and most constant customers for cheap febrifuge alkaloids from British India. Opium is now employed as the medicine which is cheapest and most readily obtained. If cinchona alkaloids should come into competition with opium, and obtain the preference by their lower price, their immense superiority would produce a revolution in the Chinese consumption of the two drugs. By this process a solution would be found for the dangers and uncertainties of the large opium revenue of India, and for the perplexing moral questions connected with it.

Hernia, Strangulated and Reducible. With Cure by Subcutaneous Injections, together with suggested and improved Methods for Kelotomy. Also, an Appendix giving a short Account of various new Surgical Instruments. By JOS. H. WARREN, M.D. Boston. London: Sampson Low and Co. 1880.

ALTHOUGH, in accordance with the title of the work, it embraces a good deal more, it is only the description of Dr. Warren's operation for the radical cure of reducible hernia that will prove of interest to most English surgeons. It will be remembered by some that many years ago an American surgeon, Dr. Heaton, visited London, and, under the patronage of Sir W. Fergusson and others, demonstrated an operation for the cure of hernia by means of a subcutaneous injection of a decoction of oak bark upon and around the hernial rings. Dr. Warren has devoted much attention to this subject, and professes to have improved, if not perfected, the original operation of Heaton. With a special syringe armed with a flat blunt oval needle spirally twisted he injects a few drops of a mixture of decoction of oak bark, ether, alcohol, and morphia along the hernial canal, and especially around the "rings." By this he excites an exudation of plastic lymph, which closes the rings and canal, and prevents the redescent of the hernia. There are of course many details of the operation and after-treatment that our space forbids us to notice fully here, which have in view the protection of the peritoneum and neighbouring vessels, and the complete organisation of the lymph before any strain is put upon it. Considerable success is claimed for this method by Dr. Warren, who says that he has cured as many as from 80 to 85 per cent. of cases operated upon; but unfortunately we have no statistics at all given us, and the statement is confessedly a merely approximative one. Dr. Warren visited this country last autumn, and operated on some cases of Mr. Bryant's at Guy's Hospital, and it would be interesting to know from an independent source what success he then achieved, and also whether Mr. Bryant has himself practised this method subsequently, and if so with what results. The benefit conferred upon mankind by anyone who would introduce a simple and effectual cure for hernia would be almost incalculable, and all will receive with cordiality any honest attempt to attain such an end. The author's spiral-ended or vermicular instruments were exhibited at Cambridge in August last, and have been noticed in our columns.

THE CHLOROTIC MURMUR.

To the Editor of THE LANCET.

SIR,—I note that in your last issue Dr. Byrom Bramwell somewhat unwarrantably couples Naunyn's name with mine in a statement he makes as to the chlorotic murmur, in which he quite mistakes my views.

To Naunyn belongs the great merit of first showing that a murmur often found in mitral stenosis in the neighbourhood of the pulmonary artery is not arterial, but auricular, in character. I am not aware that Naunyn has written anything at all about the chlorotic murmur. To myself alone belongs the merit or demerit of connecting together the observations of Beau, &c., as to the dilatation of the heart in chlorosis, with Naunyn's observation as to the dependence of a basic systolic murmur having a certain well-defined position of maximum intensity upon mitral regurgitation. I have endeavoured to show that the chlorotic murmur has this position of maximum intensity, and that the assumption that it depends upon curable mitral regurgitation is the only one which is consistent with the mode in which this murmur progresses from area to area, or which can explain and make intelligible the various views which have been held as to its origin. I have nowhere denied that the chlorotic murmur is ever arterial; I have only endeavoured to prove that in its earliest phase it is strictly cardiac in character, and that the arterial murmur in chlorosis is a late development, largely due, as Beau has pointed out, to the large blood wave sent on by the dilated and somewhat hypertrophied left ventricle. As my second edition is not yet ready, and the first is out of print, I may for the present refer Dr. Bramwell to a paper on "The Position and Mechanism of the Hæmic Murmur," published at page 383 of THE LANCET in September, 1877, where my views will be found fully detailed.

I only notice this misstatement in self-defence, but I had better guard myself against being supposed to homologate all the other doctrines propounded by Dr. Bramwell in the same paper, some of which I regard as inconsistent with fact, and others with physiology and with the physics of the circulation; in this respect I may specially refer to the theory that the aortic valves close first in the case of a reduplicated second accompanying mitral stenosis.

I am, Sir, yours sincerely,
Edinburgh, Jan. 20th, 1881. GEORGE W. BALFOUR.

PRESENTATION.—On Saturday, the 22nd inst., Dr. C. Swaby-Smith of Seaforth, near Liverpool, was presented with an appropriate address accompanied with a purse of money by the Committee of Management of the Seaforth National Schools, in recognition of his services as Honorary Secretary during the past seven years.

THE LANCET.

LONDON: SATURDAY, JANUARY 29, 1881.

Our readers will remember that a question, describable as one of etiquette, and arising out of the case of Regina *v.* Ingle, tried at the Central Criminal Court August 5th, 1880, was referred to the President and Censors of the Royal College of Physicians. The facts may be recalled in a few sentences. Louisa Morgan, a married woman, aged twenty-six, was admitted at Guy's Hospital, under the care of Dr. Pavy, on June 9th, with maladies which, either at that time or afterwards, were recognised as "old and quiescent phthisis, suppurating cyst in broad ligaments, acute inflammatory mass (tubercular) in cortex of brain." The case ended by the death of the patient on July 21st. On July 6th Louisa Morgan was found to have become suddenly worse, and it appeared that on the previous day she had, without the instructions of the physician, received "a very prolonged bath," with "almost cold water, remained in it for a considerable time," and seemed "to have suffered from a severe mental shock." Just at that time Guy's Hospital was in the height of its troubles under a "new system of nursing" which the medical staff did not approve, and Dr. Pavy believing that the death of his patient was accelerated by the use of the bath and the manner in which it was administered, an inquest was held, and the Nurse Ingle committed for manslaughter. The case was detailed, and its principal bearings discussed in these columns, on August 14th, 1880. The main features will be, therefore, as fresh as need be in the recollection of all who care to follow the issue. Sir William Gull, a consulting physician of Guy's Hospital, not having seen the patient during her life or her body after death, and therefore basing his judgment of the case on the evidence given by Dr. Pavy at the inquest, together with certain clinical notes and records of the post-mortem examination, arrived at the conclusion that the death was due to disease existing prior to the bath, and that, in point of fact, the nurse was unduly pressed. Acting on this view of the case, he appeared in Court and gave evidence which tended to show that the pathological condition of the deceased had not been fully recognised, and that the death might be fairly referred to natural causes.

Setting aside, for the moment, the terms and manner of this evidence, the question arose whether it was in accord with professional etiquette for a physician not concerned in the case, but connected with the hospital, to appear in opposition to a colleague, and publicly impugn the accuracy of his diagnosis without having himself seen the patient or even examined her body. It was obvious, and is admitted on all hands, that the presumption set up and maintained by Sir William Gull on behalf of the nurse rested on an assumption of error in the view taken of the disease by Dr. Pavy. If the physician in attendance was right, the death had been accelerated by the bath. If the physician *not* in attendance was right, the death occurred from the natural development of the disease. Both opinions could not be right; and inasmuch as one was formed at the bedside and in the post-mortem room, while the other rested on second-hand evidence, it became a question of etiquette referable to the College of Physicians whether the proceedings taken and the evidence given by Sir William Gull were strictly professional. The President and Censors of the College have replied as follows:—

"The President and Censors of the Royal College of Physicians, having carefully considered Dr. Pavy's complaint, and Sir William Gull's reply to that complaint, do not deem the character of the evidence which a Fellow or Member of the College has given on oath in a Court of Justice a proper subject to investigate when the Court has expressed itself satisfied in regard of the truthfulness and sincerity of the witness. They consider Sir William Gull, holding the opinions he expressed on oath, justified in going into Court. They are further of opinion that Dr. Pavy's diagnosis and treatment of the woman afford no grounds for any remarks calculated to disparage his well-deserved reputation as an eminent and skilful physician."

Could anything be more grotesque? After carefully considering the statements of Dr. Pavy in appeal, and Sir William Gull in rejoinder, the President and Censors "do not deem the character of the evidence which a Fellow or Member of the College has given on oath in a Court of Justice a proper subject to investigate when the Court has expressed itself satisfied in regard of the truthfulness and sincerity of the witness." If this is the principle on which the College acts, why did not the Board at the outset decline to consider the case? Or was it only after making an attempt to get to the bottom of the question they discovered that it was one into which they had no business to pry? Then, again, what in the name of common sense does the College mean by a court of justice expressing itself as satisfied of the truthfulness and sincerity of a witness? It must be perfectly well known to every member of the Board that it is not the practice of courts so to express themselves. Witnesses do not commonly make their exit with certificates of truthfulness and sincerity. There was no question as to the "truthfulness and sincerity" of the evidence given by Sir William Gull and Dr. Pavy. It would be an insult to these gentlemen to suppose they needed the expressed satisfaction of any court to accredit their testimony. Yet this is the ground on which the President and Censors declined to investigate the character of the evidence given! Having thus delivered itself, the same authority proceeds to declare that "Sir William Gull, holding the opinions he expressed on oath, was justified in going into court," but is "further of opinion that Dr. Pavy's diagnosis and treatment of the woman afford no grounds for any remarks calculated to disparage his well-deserved reputation as an eminent and skilful physician." Why the sole aim and purpose of Sir William Gull's evidence—the only effect it could have in the case—was to show that Dr. Pavy's diagnosis had been defective! A decision which decides nothing, which rests on contradictory propositions, and stultifies itself will not satisfy the profession, and we should be astonished to hear that it gave the least comfort to either of the gentlemen interested in the appeal. The President and Censors of the Royal College of Physicians have again signally proved the incompetency of that august body to act as a tribunal of etiquette. Whatever else it may be fit for, it cannot rule the practice of the profession or lay down principles of conduct by which the amenities of professional life can be governed, so that right may be done to all men, and a good understanding may prevail. The final appeal now lies to the profession, and we will not shrink from an expression of the opinion which, as we believe, the profession has formed.

Sir WILLIAM GULL, beyond question, acted with perfect sincerity and the high motive of sympathy with an accused person whom he believed to be unduly pressed. He conceived, on reading the reports of the case, that the death might have been due to the disease and not to the bath, and so feeling, he came forward, or consented to be called, in defence. In thus acting, we have no doubt, he intended to serve the cause of justice and scientific truth, but we are not the less on that account of opinion that Sir WILLIAM GULL was wrong. It ought to have been evident to him that, as consulting physician of the hospital, it was a duty he owed his colleagues to confer with them before acting. It cannot be forgotten that he knew nothing of the case except by report, or obviously imperfect and insufficient documentary evidence. It is at all times a grave step to impugn the accuracy of a diagnosis after the death of the patient, and we can scarcely conceive of circumstances under which a practitioner would be justified in so doing without something much more trustworthy, as the material of a retrospective judgment, than any evidence or testimony Sir WILLIAM GULL had before him. We are bound to say that the clinical report, which we publish in another column, does not appear to us to convey any definite information in the case. We think it was a mistake to produce such a report in Court. There is, or ought to be, a full and clear record of every case treated in a public hospital, on which reliance can be placed. If such reports do not exist at Guy's Hospital, it is impossible to think that hospital has progressed with the times. Such records were duly and diligently made by the resident officers of hospitals thirty years ago. Why are they not made now? Have modern improvements in clinical method rendered close and accurate observation unnecessary? We do not see that Sir WILLIAM GULL—once in the witness-box and committed to the error of appearing in reference to a case of which he had no personal knowledge—can be blamed for commenting on the clinical notes and reports before the Court, seeing that they had been legally put in evidence. We think he would have done wisely to decline giving any opinion on grounds so meagre, but the documents in question were legally part of the case for the prosecution. Dr. PAVY'S position in the matter is, of course, unaffected by what has transpired. No member of the profession —including Sir WILLIAM GULL himself—ever entertained a thought disparaging to that distinguished physician.

The *contretemps* has been one of a most regrettable character, and the sooner it is forgotten the better. Meanwhile, we must say that the course taken by Dr. PAVY in declining to give a certificate of the cause of death, and thus necessitating an inquest, was inevitable, and in the interests of simple justice and common humanity. With the legal issue of the case neither the physician nor the profession have any concern. It would not be tolerated that a nurse should administer a bath without the instructions of the medical officer in charge of the case. As death followed in a manner which was thought to connect the bath with the fatal issue, it was a plain duty to refer the facts to judicial inquiry. The only subjects of professional regret are those to which we have adverted—namely, that Sir WILLIAM GULL should have deemed it a matter of personal duty, and consistent with his position as a consultee and holding official relations with the acting staff of Guy's Hospital, to interpose, or, interposing, to base any critical and retrospective opinion of the case on such slender and manifestly untrustworthy reports as were at his disposal; and that the physicians of Guy's Hospital do not cause to be kept and preserved clinical records of every case treated in the wards of that institution, made by skilled and responsible qualified observers, analogous to the qualified and salaried house-physicians and house-surgeons of times past, and of a nature to be produced in evidence on any emergency, without question as to their value, or the possibility of their being either repudiated or impugned. Surely this should form part of the duty of a hospital staff. It cannot be that only private records are required? There ought clearly to be a hospital clinical register duly kept and officially preserved. The profession may now hope that we have heard the last of a case which it has been most painful to investigate, and from the consideration of which we retire with a sense of relief. It is a story that points its own moral; enforcing the need of *esprit de corps*, and teaching a lesson of fraternity which the profession should be careful to learn and refuse to allow its members to ignore.

SINCE the use of the Hampstead Hospital of the Metropolitan Asylums Board for the reception of cases of small-pox in 1871-72, the common belief of the population resident in the near vicinity of the hospital that the contagion of the small-pox patients accumulated there was diffused from the hospital buildings to susceptible people inhabiting adjacent houses has become firmer and firmer. Each successive use of the hospital for small-pox has appeared to them to lend support to this belief, and later events in connexion with the small-pox hospitals of the Asylums Board at Homerton, Stockwell, and Fulham have been held to add further confirmation to it. But although ten years have passed since the rumour of this belief first reached the public generally, and within that period has grown upon the public so as to form now a formidable impediment to the provision of proper hospital room for the accommodation of small-pox patients, not only in the metropolis, but also in the provinces, no sufficient investigation has been made by those whose duty we hold it was to make such investigation into the circumstances under which the rumour first arose, and into the degree of truth or error underlying it, and the belief which has now so generally grown out of it. There were two points to be considered—first, the strictly medical point of the conditions under which, and extent to which, the contagion of small-pox admitted of being diffused through the atmosphere; and subordinate to this the indirect means in which the contagion might be apt to be disseminated in the carrying of small-pox patients to a hospital, and their dismissal thence when convalescent. Next, and depending upon the answers to be given to the first question, there was that of the public policy involved in the accumulation of large numbers of small-pox patients in the near vicinity of inhabited houses.

With regard to the first question, at the time of the establishment of the Asylums Board Small-pox Hospitals all trustworthy medical evidence pointed to the conclusion that fear of diffusion of small-pox contagion through the atmosphere from a ward occupied by small-pox patients need not be entertained, and that the indirect means of dissemination of the contagion by patients conveyed to and dismissed from a small-pox hospital might be readily controlled. And these general conclusions were apparently fully confirmed by the results of the inquiry made by THE LANCET Sanitary Commission when the rumour of extension of small-pox from the Hampstead Hospital to neighbouring houses became alarming. The Commission was unable to ascertain any reasonable ground for the belief that contagion had been diffused from the wards through the atmosphere; and such evidence of extension as was discovered pointed to indirect but well-known ways in which small-pox is disseminated, and it was found difficult in all cases to say whether the extension came from patients in hospital or from patients among the general population outside the hospital, who had contracted the disease elsewhere in the metropolis. One thing, however, was made evident, that full light upon the subject could only be obtained by inquiry in detail into individual cases of asserted contraction of the disease from the hospital, and this alone could be done by the Central Government itself undertaking the inquiry.

And here we come to the initial misfortune of the whole of this troubled question. The Metropolitan Asylums Board at the time of the institution of the metropolitan small-pox hospitals was purely a Poor-law authority, and, acting strictly within its legal functions, it ignored almost wholly the general public health phase of these hospitals. In their establishment for Poor-law purposes, the principles as to infectious disease hospitals involved in the Sanitary Act, 1866, were overlooked, and in the whole of the discussions which took place upon these hospitals the department of the Government then concerned with the public health administration of the kingdom—namely, the Privy Council—was, we believe, never consulted! But, more astonishing still, when the Poor-law Commissioners and their functions were merged in the Local Government Board, which had entrusted to it both the Poor-law and Public Health administration of the kingdom, still the public health aspect of these hospitals was ignored, and, as a consequence, their usefulness is now gravely impeded, and, we learn on good authority, the erection of infectious disease hospitals throughout the kingdom brought practically to a standstill. In another column our readers will be glad to see that the Local Government Board appears at last to be recovering from the judicial blindness which in this respect has fallen upon them. It is known that Dr. THORNE THORNE has been for some time engaged in an inquiry on, and the results obtained from, the erection of infectious disease hospitals in various parts of the kingdom. It now appears that he is devoting his attention, among other things, particularly to the question of extension of disease from them. In continuation of that inquiry he has now been directed, in conjunction with Mr. W. H. POWER, to inquire into the reported extension of the contagion of small-pox from the Metropolitan Asylums Board's small-pox hospital at Fulham. As a first step in this important inquiry, Dr. THORNE THORNE has issued a circular to the medical practitioners residing within a mile of the Fulham Hospital asking for information as to *all* cases of small-pox falling under their observation during the next three months, and for their assistance in tracing these cases to their source. Here, then, we have an inquiry begun in the metropolis of a sort which can alone help to a full knowledge of the influence of the metropolitan small-pox hospitals in respect to the dissemination of contagion in their neighbourhoods. Having regard to the importance of the professional and public questions at issue, we sincerely trust that Dr. THORNE THORNE and Mr. W. H. POWER will receive from the medical profession in Fulham and the vicinity of the hospital the most cordial assistance.

◆

THE answer of Mr. MUNDELLA to Mr. ERRINGTON on the subject of Medical Legislation, which will be found in our Parliamentary notes of last week, seems to us as satisfactory as it could be in the most exceptional circumstances of the Legislature. Mr. MUNDELLA sees no probability of a Medical Bill being discussed and receiving proper attention this session, and therefore the Government did not intend to introduce a Bill; "but they thought it probable that some advantage would result from the continuation of the inquiry" by the Select Committee. The Vice-President said the matter was under consideration, and he promised to confer with Mr. ERRINGTON about it. To our thinking the evidence obtained already by the Select Committee of the last Parliament contains ground enough for a Bill amending the constitution and powers of the Council, and the constitution of the Licensing Boards of the kingdom. Without the Government accepting the responsibility of formulating a Bill, it may yet see its way to support a measure which is announced as being framed by a conference representing pretty fully the profession itself, and introduced by Mr. HARDCASTLE and others. This Bill will, it is stated, be very shortly before us and the public. If a satisfactory measure, it should be pressed on the attention of the House of Commons, and either adopted absolutely, or, if a Committee is to be appointed, it should be referred to the Committee with the other Bills which have been more or less considered. We consider the case ripe for legislation. If ever a public body has proved itself costly and incapable, it is the Medical Council, which is, unfortunately, the official source of all information to Government. The competing and complicated Examining Boards, with their half diplomas, are a scandal of fifty years' standing; and the imperfection of the means of distinguishing qualified from unqualified practitioners, with the consequent prevalence of fraud and imposture, are notorious public evils. So far we think the case for Reform "ripe and over-ripe." Still, we accept Mr. MUNDELLA'S language in perfect good faith. If he thinks that further opportunity should be given for developing the case for or against legislation, and that there is no probability of the Government accepting and helping forward a good Bill even prepared to their hand, then we shall acquiesce in the further inquiry, feeling that it can only go to confirm the case for legislation. Before finally deciding, after consultation with Mr. ERRINGTON, Mr. MUNDELLA should certainly consider the Bill introduced by Mr. HARDCASTLE, purporting, as it does, to represent all classes and interests of the profession.

WE lately described the interesting experiments of Dr. BROWN-SÉQUARD on the effect of the application of chloroform to the skin on the functions of the central nervous system. It has been objected that the effects might possibly be due to the inhalation of some of the chloroform vapour. He has therefore repeated his experiments, and with the precaution of making the animal breathe air from another floor of the laboratory than that in which the experiments were made, its head being placed within a tube. The results obtained were the same as those already described, the only difference being that the period of excitement which usually precedes that of complete resolution, was a little longer than in the experiments already published. During this period, which is frequent, although not constant, the respiratory and cardiac movements are more rapid and more energetic. The animal cries and is disturbed—it appears hyperæsthetic, and its rectal temperature is raised a fifth or a quarter of a degree Centigrade.

Dr. BROWN-SÉQUARD, in a fresh series of experiments, has ascertained that the influence of chloroform on the mucous membranes is, as a rule, much more rapid and energetic than when applied to the skin. In these observations also the animals (dogs, cats, rabbits, and guinea-pigs) were made to breathe, by means of a tube fixed in the trachea, air coming from a distant part of the laboratory. Inhibition of the heart and respiration was invariably produced in a very brief, though variable time. Moreover, the loss of sensibility, of reflex action, and general resolution, with arrest of the exchange between the tissues and the blood, were frequently observed almost immediately after the application of the chloroform to the mucous membranes of the nose and larynx, or when it was poured into the mouth of a guinea-pig or rabbit. But, strange to say, the application of chloroform to the posterior part of the mucous membrane of the mouth of the dog, or to the surface of the pharynx, always produced the opposite effect to the inhibition observed in the other animals. Respiration is greatly augmented, one dog, for instance, breathing 160 times a minute. Thus the effect in the same animal is altogether different when the chloroform is applied to the laryngeal mucous membrane, than when it is applied to the adjacent mucous membrane in the pharynx and mouth.

The influence of chloroform poured into one nostril upon the diaphragm and phrenic nerves is exactly the same as that produced when it is applied to the side of the thorax or to the shoulder. There is a loss of the equilibrium between the action of the two halves of the diaphragmatic apparatus; the phrenic nerve and the half of the diaphragm on the side corresponding to the nostril irritated become more energetic both in the degree and in the duration of their action, after the thorax has been opened, while those on the other side present the opposite condition.

Chloral hydrate, even in the most concentrated solution, when applied to the skin, does not usually produce any of the anæsthetic or other effects which follow its injection into a vein or beneath the skin. This is, however, not true when a large area of the skin is irritated by anhydrous chloral. The effects of this are perfectly analogous to those of the application of chloroform. The only differences are that the chloral acts more slowly, but causes death more readily; that it causes pulmonary, renal, and intestinal hæmorrhages more frequently than chloroform, and that it produces abundant secretions from various abdominal glands, and so causes diarrhœa, an effect which is never produced by chloroform. Chloral seems to cause glycosuria, which chloroform never does, and is apparently absorbed by the vessels of the skin to a much greater extent than chloroform. Inhalations of anhydrous chloral or its application to the skin, do not produce anæsthesia except at the moment of death. In the guinea-pig especially, which is rendered anæsthetic so readily by the inhalation of a very small quantity of the vapour of chloroform, the inhalation of chloral has very little anæsthetic effect.

WE observe, with regret, that before the promised Warrant regulating the conditions of service in the Medical Department of the Navy has been promulgated, the usual advertisement has been issued by the Admiralty of an examination of candidates for commissions, to be held on Feb. 14th and following days. We cannot but think that in adopting this course they have committed a serious mistake. It is true that an intimation is given that "new regulations giving naval medical officers generally the same relative pay, position, &c., with reference to Army medical officers, as formerly existed, will shortly be published." But this is surely much too vague a statement of benefits to be conferred to satisfy any of the class of young medical men who would be likely to prove desirable candidates, and it refers only to the relative position with regard to the Army medical officers. Nothing is said of any intended change in the regulations regarding compulsory half-pay, nor of the privilege of choice of cabins according to rank being assured to them, nor of the abolition of the obnoxious rule requiring five years' service in the rank of Deputy before being eligible for promotion to that of Inspector-General. We are unwilling to suppose that there is any reason for withholding the Warrant till after the examinations are over, but we cannot understand the delay. The failure to obtain candidates has been too long manifest. The Committee appointed to inquire into the causes of this has long since made its report. There has been abundance of time to consider this report and to decide upon the necessary measures, and the wording of the advertisement itself seems to imply that these have already been settled. Why, then, have they not been published? We are most reluctant to say anything that would even seem to be injurious to the public service; but a sense of duty to the profession, and an earnest desire to promote the best interests alike of the Department and of the Navy generally, compel us to advise any medical men who may be desirous of entering the Service to withhold their applications till the new Warrant makes its appearance. We can conceive few things more injurious than that men should engage to enter a Service on unknown conditions and vague promises, or more likely to create a discontented and inefficient Department should these prove to be less satisfactory than was expected. Up to the time of our going to press the Warrant is not, at least, in the hands of the profession. We would urge in the strongest manner upon the Admiralty the expediency of bringing out the Warrant at once if they desire to have a fair supply of well-qualified candidates. The delay which has taken place has already diminished the chance of an adequate number being obtained on this occasion; but, unless prompt measures are adopted, there is every probability of the intended examination proving as complete a failure as those of the last two years.

Annotations.

"Ne quid nimis."

FROST AND MORTALITY.

THE fatal effect of severe winter weather, called seasonable, upon the public health is once more exemplified in the Registrar-General's weekly return. During the six weeks of mild winter weather ending 8th inst. the weekly number of deaths in the twenty large English towns dealt with in that return averaged 2971, whereas in the two following weeks they rose to 3444 and 4199. This represents an excess of mortality in the two weeks equal to 1701 deaths in the twenty towns. It has often been shown in the reports of the Registrar-General that the effect of intense cold is fully as great upon the mortality of rural as upon that of urban populations. We may therefore assume that the effect of the severe frost which set in on the 12th inst. on the registered mortality of England and Wales up to Saturday, 22nd inst., was to add to the register the record of not less than 5749 deaths of persons who would have survived if the mild weather had continued. This simply represents the number of those killed outright by the first week of the frost, and affords but a slight indication of what the losses to the population would have been from a continuation of the intense cold. The above figures take no account of the wounded in the first week's conflict with the weather, who will the more readily succumb if the conflict be prolonged. It will be many weeks before it will be possible to sum up the total losses due to this arctic weather. It must not be supposed that the losses fall chiefly upon the weakly, the elderly, and infirm, as these figures show that the largest proportional losses were among male adults aged from thirty to fifty, upon those whose occupations entail upon them most risk of exposure.

PASSIVE CONGESTION OF THE SPLEEN.

AT the suggestion of Virchow, the histological changes in the spleen which result from passive congestion have been studied very carefully by Dr. R. Nikolaides. In the indurated organ, the naked eye can detect a thick white layer around the vessels, which renders the tint of the section a paler red than might be expected. Under the microscope the walls of the bloodvessels, and especially those of the arteries, are seen to be enormously thickened by an increase of the adventitia and the adjacent zone of tissue, which passes gradually into the neighbouring reticulum of the splenic pulp. The trabeculæ are thickened, and the contiguous cells of the pulp undergo atrophy, just as do the outer cells of the acini of the liver in cirrhosis. These changes are more or less marked in all congested spleens, and confer upon the organ its increased density. Their degree appears to depend upon the slowness with which the mechanical congestion is developed. Besides these changes, alterations occur also in the intima of the vessels. They are most marked in the arteries, and are only found in the veins in very chronic cases. In the veins the change consists in merely fatty degeneration; but the inner coat of the arteries presents an overgrowth of all the connective tissue layers—a true endarteritis, similar to that which Virchow has described in the veins of some other organs, as the lungs and liver, in passive congestion. It is difficult to say whether the muscular coat of the vessels is thickened or not; but Nikolaides believes that there is a considerable increase in the circular muscular fibres. Not only is this conclusion suggested by histological examination, but it is remarked that the mechanical congestion of the spleen never entails the degree of hyperæmia met with in other organs, as the liver and the kidney, in spite of the fact that the circulatory arrangement of the spleen is highly favourable to the occurrence of such hyperæmia. This fact is regarded as supporting the view that in congestion the muscular walls of the arteries contract, overgrow, and lessen the hyperæmia. The evidence on this point seems scarcely conclusive. Some share in this effect might be ascribed to an overaction of the muscular fibres proper to the splenic pulp, since it is difficult to understand, without such overaction, how the blood could be lessened in an organ, like the spleen, destitute of capillaries, by contraction of the arteries, if there exists an obstruction to the exit of blood. The splenic follicles, Nikolaides believes to take no part in the overgrowth of tissue which results from passive congestion.

SANITARY PROGRESS IN ARCHITECTURE.

A REFERENCE to the last number of our excellent contemporary the *Builder* affords conclusive evidence that the members of the architectural profession are gradually becoming fully alive to the necessity of attending to the sanitary arrangements of our public and private buildings. We find, in the first place, an extensive report of a debate at the Royal Institute of British Architects on the relations of sanitary science to civil architecture. The debate was *à propos* of a very able paper read by Mr. E. C. Robins, F.S.A., the Architect to the City Guilds, on November 29th, 1880; and as one evening was insufficient for so extensive a subject the discussion was resumed on the 17th inst., when, after a very interesting debate, it was found necessary to again adjourn it till the 14th of February next. We feel no little sympathy with those gentlemen who regard architecture mainly as a fine art (and who are furnishing us with edifices calculated to please the eye to a maximum extent), yet find that the requirements of civilisation and modern city life necessitate their directing attention to matters which are the very reverse of æsthetic. When we think of a genius like Michael Angelo turning his divine intellect to the contemplation of a soil-pipe, we confess that it seems like a "god kissing carrion." But the necessity has arisen; people feel that the most magnificent structure is but a whited sepulchre if sewer air gain access to it, and accordingly the heads of the architectural profession, led by the President of the Institute, Mr. Whichcord, are manfully facing the cruel duty imposed upon them, and we may soon look to having our buildings constructed with all the safeguards which sanitary science has yet suggested. It was not to be expected that architects would yield to sanitary exigencies without grumbling, and accordingly one architect was found to advocate the sending of "waterclosets, pipes, and plumbing of every kind outside the house" (as though such a course were possible in London), and another turned upon the sanitarians with a taunt that the whole of sanitary science was only tentative and experimental, and that it had no claim to be considered exact or finite. We trust not; we do not know of any branch of science which is finite. The word "progress" has a welcome sound in the ears of scientists, and we could only wish that architects were less content to copy Grecian or Venetian models for their houses, and by trying to adjust antique models to modern requirements, give us at the same time the diseases which depopulated Athens and decimated Europe in the Middle Ages. Alongside of the account of this debate is a verbatim report of a lecture delivered by Mr. Robins to members of building societies, at the Parkes Museum, the subject being ventilation, lighting, and warming. The lecturer, by his frequent quotations from Parkes, De Chaumont, Galton, Corfield, and other writers on the science of hygiene, showed he completely recognised that henceforth those who practise architecture as a fine art must be votaries at the shrine of Hygeia, if their edifices are to be altogether lovely. In addition to the foregoing we find an able editorial article on "the Campaign against Preventable Human Misery," in which the writer, after alluding to the sanitary associations which have lately arisen among us, devotes his attention mainly to the "*burning* question" of smoke prevention, and his remarks are tempered by suggestiveness and sound common sense. In bedrooms and dressing-rooms the writer is of opinion that some of the gas-fires which have already been invented will be found to answer the purpose. In the nursery, in consequence of the absolute necessity of a free supply of fresh air, he advises the retention of the ordinary open grate as we have it at present. In the kitchen the writer thinks that "culm," composed of anthracite-dust welded into balls with the aid of clay, a fuel much used in Pembrokeshire, would prove both smokeless and economical. For the drawing-room fires of the rich, wood or cannel coal should be employed, and this, the writer affirms, "is the very poetry of open fires." He appears to take the view that the main difficulty in the smoke question is to be found in the various domestic hearths, and that the tall chimneys of manufacturers may be reduced to reason without much difficulty.

BOOTS.

THE discomforts of an inclement season are mainly due to having to encounter it in unsuitable clothing, and we believe that the pleasures of out-door exercise are, to the young, enhanced rather than otherwise by boisterous weather, provided the apparel is calculated to resist it. Of all articles of clothing nothing is more important in weather such as we have been lately enduring than the boots, and the quality of these largely affects the power of the individual to avoid the risks attendant upon snow and thaw. A cheap pair of machined boots made of green absorbent leather, and stitched with unwaxed thread, are admirably calculated to eat up the saving in their initial cost with a bill for medical attendance, and it should be remembered that in purchasing boots it is of prime importance to see that the leather is properly tanned and well seasoned, that the threads are waxed and the stitches sufficiently close. At such a time some extra protection for the feet is commonly resorted to, and for those who need an overshoe to keep the feet clean and dry when paying visits of ceremony, there is nothing better than the American overshoes made of cloth and india-rubber, and popularly known on the other side of the Atlantic as "Jemimas." These keep the feet warm as well as dry, and are a great improvement on the old golosh. To keep the feet warm, however, there is nothing like brisk walking, and overshoes of all kinds are a great hindrance to exercise. How can we get exercise and keep the feet moderately dry as well? That is the problem to be solved. In very bad weather the boots should be greased or dubbed instead of being polished, and it will be found that water will run off upper leathers so treated. The absorbent sole, however, remains, and no matter what thickness of leather be used the sole gets to a certain extent saturated after a long walk in the damp, and the evaporation from a wet sole is the great cause of cold feet when the exercise is finished. It is a great object to keep the absorbent sole out of the damp if possible. To effect this there is no better contrivance than the very homely one of having a few hobnails driven into it, and since these may be quickly applied to any pair of boots, and do not (or need not) materially increase the weight or clumsiness of the boot, we think such a course is strongly to be recommended. The advantages of them are the following:—1. They keep the sole from one-eighth to a quarter of an inch off the damp ground. 2. They give a firm hold on snowy or greasy pavements when locomotion is almost impossible in ordinary boots. 3. They allow the sole to drain of such moisture as it picks up, and by keeping a layer of air beneath the sole and the damp ground they increase the warmth of a boot just as the familiar expedient of a wisp of straw keeps the foot warm when placed inside a boot. 4. They are very cleanly, and by giving fewer points of contact between the sole and the ground they prevent to a great extent the splashing which is caused by the sharp contact of a wide heavy sole with a sloppy pavement. There are undoubtedly disadvantages, the chief of which is the sound; but, on the whole, in damp weather hobnails are a rare luxury, and we believe that those who are tempted to follow our advice will not blame us for devoting a few lines to the hygiene of "clouted shoon."

THE CIRCULATION IN MARROW OF BONE AND CEREBRAL MENINGES.

KOLLMAN, in a series of investigations into the circulation in the medulla of human bone, has corroborated the statements of Hayer and Rindfleisch that this circulation is not continuous through vessels, but that the minute veins open into the interstices of the tissue. In spite of this interruption, the circulation goes on with perfect regularity. Aqueous solutions of Berlin blue find their way from the veins to the arteries as readily as from the arteries to the veins, and, what is still more remarkable, they find their way from the sub-arachnoid space of the spinal cord, to the spongy structure of the skull, into the sinuses of the dura mater, and into the veins of the skull and of the face. It is conjectured that the communication between the sub-arachnoid spaces and the veins is by means of the Pacchionian granulations. The sub-arachnoid and subdural spaces of the brain are not in direct communication, but the injection readily passes from the subdural space into the periphery of the Pacchionian granulations and so into the venous sinuses. There are also fissures in the inner surface of the dura mater which are openings into the lymphatic canals.

THE ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.

THIS hospital is passing through a period of some difficulty. The funds are not in a flourishing state, and amongst the remedies proposed is an alteration in the out-patient department. At the recent annual meeting of the governors and friends of the institution it was alleged that many abuses exist, and that many persons get out-patient tickets who are able to pay for medical attendance. It was alleged also that the medical officers were sometimes late or absent in the out-patient department. With a view to meet these evils, it was proposed by the committee to establish a provident dispensary in connexion with the hospital, and at Southsea, and to expend a sum not exceeding £200 annually in remunerating the medical officers who may be appointed to attend the out-patients and the members of the provident dispensary. Further, it was proposed, in order to give effect to the first resolution, to suspend certain rules of the institution affecting the appointment and rights of the medical men. This proposal came upon the medical men unexpectedly, and was warmly objected to. Dr. Cousins therefore proposed, as an amendment, that the scheme should be examined and reported on by a special committee, to consist of the committee, the honorary medical officers, and eight subscribers, chosen from the members. A long and keen discussion followed. Dr. Cousin's amendment was carried by 16 to 8. We commend the subscribers for listening to the objections of the medical men, and for declining to adopt organic changes without the fullest examination of their merits and tendency. The warning of Guy's should suffice for all lesser institutions. It will be found impossible to work hospitals or dispensaries successfully without the concurrence of the medical staff. To the public of Portsmouth we would venture to say that no cause can be more worthy of their support than that of the hospital, and that no such community can relieve itself of the responsibility of upholding it. After all allowance for questions of management, or even abuse, there remains the great claim of painful and disabling suffering.

SICKNESS AND PAUPERISM.

IT is not only the present discomfort and distress occasioned by the severity of the weather that we have to contend against, but we must look forward to a considerable increase of what we may call unavoidable pauperism. Already the wards of the general hospitals and sick infirmaries of the workhouses are crowded to overflowing. At the same time a decrease is noticed in the attendances at the out-patient room. This is caused partly by the severity of the weather keeping the sufferers at home, but chiefly by the fact that the chronic cases which form so large a proportion of out-patient attendants have given up the struggle, and have been obliged to seek refuge in the workhouse. Amongst our working population there is always a large number suffering from chronic bronchitis, emphysema, and rheumatic affections, and who, if they can tide over the worst months of winter, can during the remainder of the year earn a fair wage and thus keep house and home together. In ordinary winters this is feasible, but with such a prolonged continuance of cold as we are now experiencing the struggle is too often impossible. The savings of the summer months are expended, the sufferer is unable to attend the out-patient room, and the wards of the hospital are too full to receive him; so the workhouse is his only refuge. Once there the chances are that he never ceases to be a burden on the rates. With his fellows outside he knows he has lost caste, and he also feels that the comfort and repose even of a workhouse ward are superior to those he can obtain at home. Feeling, therefore, that his old associates will shun him on account of the taint of pauperism he now bears, and shrinking from what he now thinks to be a useless struggle, he resigns himself to his fate. And so a man, who for years with a little timely assistance during seasons of illness might have supported himself, becomes a burden on the rates. If in becoming a pauper the disaster only concerned himself the mischief would be limited. But under the present system the man pauperises his wife and children. These latter, brought up under the grim shadow of the Poor Law, continue the pauper brood for generations. In this time of exceptional distress the great point to aim at is to prevent respectable families drifting into pauperism. At our great hospitals the claims for admission should be carefully investigated; this is no time for beds to be occupied by well-fed and pampered servants, or by the pensioners of the rich, when a bed may turn the scale between independence and pauperism for a whole family. The charitable, too, should use discrimination as to the institutions on which to bestow their charity; between those which have reserve funds and those which are struggling on from hand to mouth, depending only on daily and weekly subscriptions, and relying on the public to supply any deficiencies that may arise. Such advice might seem superfluous; but only to-day in the columns of a contemporary we saw an appeal from a hospital which possesses a reserve fund of over a hundred thousand pounds, and has land valued at ten thousand, stating that funds were urgently needed! Under the present exceptional circumstances hospitals with such a balance-sheet have no right to appeal to the charitable. To demand money in such a case, when there is so much suffering requiring immediate relief, is positively sinful.

COLLEGE OF PHYSICIANS OF IRELAND.

DURING the months of November and December last a large number of candidates presented themselves for the licence in Medicine of this College, and twenty-three, having satisfied their examiners, were duly admitted licentiates. This month one gentleman only obtained the licence, and the reason of this sudden decrease in the number of applicants is explained by a regulation in reference to fever certificates, adopted by the College in May last, and which came into operation the first day of the present year. By this regulation it is ordained that every candidate for the licence in Medicine shall be required to produce evidence that he has for not less than three months studied fever in a hospital recognised by the College containing fever wards, and recorded from daily personal observation at least five cases of fever to the satisfaction of the attending clinical physician. It seems that this by-law has created a good deal of inconvenience to intending applicants, and hence the falling off in the numbers, and the explanation that so many candidates underwent examination in November and December last before this regulation came into force. We believe, however, that we are correct in stating that any registered practitioner of five years' standing can be admitted, according to Regulation 7 of the College, to examination for the licence on producing his certificate of registration, and showing that he is exempted from producing the fever certificate, as well as from examination by printed questions.

BACTERIA IN THE CHOROID.

THE *Centralblatt für prakt. Augenheilk.* for October last contains a paper by the Duke Charles of Bavaria on the discovery of bacteria in the choroid coat of two eyeballs. The eyeballs, which showed neither naked eye nor microscopical evidence of disease, were preserved in Müller's fluid. On examination the vessels of both the coarser and the finer vascular network of the choroid were found closely packed with bacteria. They were especially abundant in the larger capillaries just before their ultimate division and in the finest capillaries themselves, and least numerous in the small arteries and veins. There was no sign of decomposition of the eyes, nor were any organisms found in the Müller's fluid, in which they had been immersed, while other globes contained in the same vessel did not present any similar appearances. These, together with the fact that the bacteria were only in small numbers in the veins and closely packed in the capillaries, negative the supposition that they had originated post-mortem. The bacteria were cylindrical rodlets about half the length of the nucleus of a leucocyte, with a clearly-defined outline, homogeneous, glistening, and structureless contents. Besides these, some bacilli from five to twenty times their length and some of the small rods undergoing division were found. They mostly resembled the forms of organisms seen in septic diseases and in decomposition, and they differed from the bacilli of splenic fever by their greater thickness and the slight rounding of their ends.

THE TRANSVAAL WAR.

THE Bearer Company of the Army Hospital Corps, commanded by Surgeon-Major William Johnston, under orders for the Cape, was inspected by Surgeon-General Fasson, on the Depôt Parade-ground, South Camp, Aldershot, on Monday last. The men were equipped with the white colonial helmets, and carried Martini-Henry carbines, with which they have been armed in preference to the revolver which was issued to the Army Hospital Corps in the late Zulu War. The Company paraded at an early hour on Tuesday morning, and marched to the Aldershot station, where a special train was in waiting to convey them to Southampton, where they embarked on board the Union Company's mail steamer *Danube*, which sailed for Natal that day. The marching-out strength of the Company was eight officers of the Army Medical Department, three officers of the Army Hospital Corps, two sergeant-majors, and 136 non-commissioned officers and men, with, for transport purposes, one conductor and twenty men of the Army Service Corps. The ambulance waggons, water-carts, surgery waggons, pack-saddles, stretchers, cacolets, litters, and other equipments had been previously sent from Woolwich arsenal and shipped on board the *Danube*. The War Office authorities decided that the horses and mules for the Bearer Company shall be obtained in Natal on arrival, an arrangement which economises the transport from England; but, looking at the known scarcity of baggage animals in the Cape Colony, it is a somewhat hazardous proceeding.

UNIVERSITIES (SCOTLAND) VOTING BILL.

THIS is a Bill introduced by Dr. Lyon Playfair and others, to amend the mode of voting in elections of representatives for the Scottish Universities. The chief provisions of this Bill are to the effect that electors are to vote by voting-papers only, that these papers and letters of intimation are to be issued by the Registrar of the University, and are to be returned by the voter to him, to be kept in safe custody till counted by the returning officer. Signature before a magistrate is to be dispensed with. The candidates are to be bound by Clause 15 to pay the expenses incurred in issuing the voting-papers, and in taking the poll. These arrangements seem calculated to promote the order and keep down the expenses of University elections, and to be worthy of support.

THE MUCOUS MEMBRANE OF THE ANUS.

IN the *Journ. de l'Anat. et Phys.*, G. Hermann has recently published some observations on the structure of the anal mucous membrane. He includes in this term a circular rim from 5 to 12 mm. in depth, reaching from the narrow white ano-cutaneous line pointed out by Hilton, to the ano-rectal line above—a portion corresponding to the internal sphincter and analogous to the red free border of the lips between the skin and true mucous membrane. After pointing out that with the exception of a serous coat on the outside, the structures of this region are the same as those met with in the upper part of the intestine—two layers of muscular tissue, mucous membrane, Auerbach's and Meissner's plexuses,—he enters into fuller detail as to the structure and development of the mucous membrane. The epithelium is squamous and stratified, but columnar in the depressions between the columnæ recti of Morgagni. At the sides he finds pouches and duct-like tubes lined with simple or stratified epithelium, which dip down to the depth of one centimetre into the subjacent muscle and there sometimes branch at their extremities. He considers these to be analogous to the glands found in this situation in animals. It is also suggested that these depressions, duct-like tubes, and the closed follicles found between them play an important part in the production of anal abscess and fistula.

DUBLIN HOSPITAL SUNDAY.

THE total amount obtained by the collections last November for this fund amount to £4050, which shows a decrease of £294, as compared with that of 1879. This decrease was expected, and is undoubtedly to be attributed to the land agitation and the depression in trade, circumstances which sufficiently explain the falling off in the receipts. Each charity which participates in the funds collected is assisted (1) according to the amount of voluntary contributions received by it, and (2) by the amount of work done. Among the donations was one which may be specially referred to—viz., a sum of nearly £40, being the proceeds of a football match, played by the Irish Football Union in November last.

THE ROYAL MATERNITY CHARITY.

THE annual report of this charity for delivering poor married women at their own houses is published. The institution is 124 years old. The committee report that 3595 females have been delivered in the year, the largest number since 1867. There were but eight deaths and few other serious results. The work is done chiefly by midwives, with the assistance of the medical officers in emergencies. The results compare very favourably with those of lying-in hospitals. It is significant that, notwithstanding the generally bad hygienic condition of the houses of the poor, and all the hard conditions of poverty itself, the process of parturition should be so much more favourable in such houses than in lying-in hospitals, however well conducted.

THE DEATH OF DR. ANDREW WOOD.

IT is with extreme regret that we announce to our readers the death of Dr. Andrew Wood of Edinburgh. It occurred suddenly on Tuesday. He had been ailing for some days, but on that day resumed his professional duties. On returning from his round, he was found in his carriage lying in a state of unconsciousness, from which he did not recover. The deceased gentleman was seventy years of age. We are compelled to reserve a further notice of this melancholy event and of Dr. Wood's life till next week.

LEGACIES AND THE HOSPITAL SUNDAY FUND.

THE Hospital Sunday Fund was wise in publishing a form of legacy for the use of those wishing to use the Council of the Fund as a medium for the distribution of their legacies to Hospitals. A cheque was received at the Mansion House a few days ago for 100 guineas from the trustees of the late Mr. James Drew, of Cornwall-terrace, Regent's-park.

SUPPURATION OF ENLARGED THYROID.

SPONTANEOUS suppuration of a goitre is one of the least common terminations. An instance in which this occurred during the course of an attack of typhoid fever has lately been recorded by M. Weill, from Jaccoud's wards. The patient was a man aged twenty-two, who had a goitre of moderate size and firm consistence. He had lived until within four months in a district where goitre is endemic. The attack of typhoid fever ran a normal and mild course. The day after the temperature had become natural, he complained of severe pain in the neck, and the surface of the goitre was observed to be reddened. During the next day the redness and size of the goitre increased, and its consistence diminished, until distinct fluctuation was perceptible. A week later it was incised, and a large quantity of pus escaped. A drainage-tube was applied, and the cavity washed out daily with carbolic acid. It gradually lessened in size, and was ultimately reduced to two or three small nodules by the side of the larynx.

CLINICAL SOCIETY.

THE newly elected President, Mr. Lister, will take the chair for the first time at the meeting of the Clinical Society this evening (Friday), and will deliver an introductory address, before the ordinary business of the Society is proceeded with. Mr. Lister will take for his subject, "the Catgut Ligature," and a discussion will probably follow.

TWO warders of the Menyflatts Lunatic Asylum are in custody in connexion with an alleged fatal assault on an inmate, Cornelius O'Leary. The patient, for nearly three weeks before his death, was very violent and needed constant attention night and day. On the morning of the 3rd inst., it was pointed out to Dr. Liddell at his usual morning visit, that there was something wrong with O'Leary's chest, and on examination it was found that at least one of his ribs was broken. In two days more the patient died, and the post-mortem examination, we understand, tended to confirm Dr. Liddell's suspicion that the injury was not self-inflicted. The two attendants, who are night warders and who were with O'Leary the night before the injury was discovered, have been before the Sheriff and were committed for further inquiry.

THE subscribers to the "Habershon and Cooper Forster Testimonial Fund" are already numerous, and it is not intended to delay the presentation for any length of time. We have been asked to state that the list will be closed on Feb. 28th. Guy's men who wish to subscribe will therefore do well to communicate at once with the Treasurer, C. A. Aikin, 7, Clifton-place, Sussex-square, W.; or with one of the Secretaries—H. Morris, 2, Mansfield-street, Portland-place, W., or F. Durham, 38, Brook-street, Grosvenor-square, W.

AT the meeting of the Epidemiological Society on Wednesday, Feb. 2nd, at 8 P.M., Dr. Squire will read a hitherto unpublished letter by Dr. Edward Jenner, containing "Instructions for Vaccine Inoculation," in the possession of Mr. Symonds, F.R.C.S., of Oxford. Surgeon-General Gordon will afterwards introduce the subject of Cholera and Fever, especially with reference to their occurrence in India and China.

MR. ERNEST CRAVEN LUNN, L.S.A., whose name appears this week in the list of gentlemen who obtained the Membership of the College of Surgeons on the 20th inst., whilst waiting at the doors of the Gaiety Theatre with a young lady, whom he was about to marry, was knocked down by a cab, and instantly killed; his betrothed at the same time sustaining a fracture of one of her legs.

A CONFERENCE of anatomical teachers will be held next Thursday evening (Feb. 3rd) at the Middlesex Hospital to consider the propriety of taking steps to remedy the prevailing scarcity of subjects for dissection.

AT the meeting of the Quekett Microscopical Club this evening (Friday) Dr. Cobbold will read a further communication from Dr. Manson, of Amoy, on Filaria.

DR. J. J. LUCE, the accident to whom we recorded on the 1st inst., is, we are glad to learn, recovering from the serious injuries he received by being thrown from his vehicle.

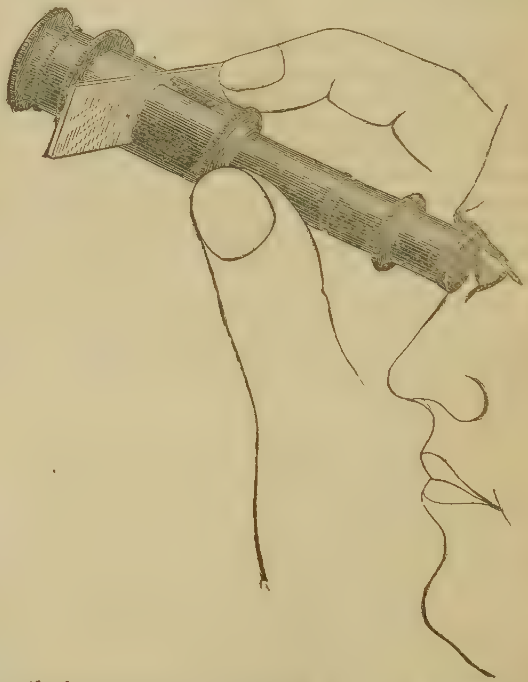
WE may remind our readers that at the meeting of the Pathological Society to be held on Tuesday next the President (Dr. Wilks) will deliver his introductory address, which was postponed from the last meeting on account of the severe weather having caused only a very small attendance of members.

JOHN HOUSLEY, M.D., and E. M. C. HOOKER, L.R.C.P. Lond., M.R.C.S. Eng., are candidates for the vacant Coronership of East Retford, Nottinghamshire, and have each issued an address to the freeholders.

New Inventions.

NEW POCKET MICROSCOPE.

WE have received from Messrs. Salt and Son, surgical instrument makers, Birmingham, a small pocket microscope for the examination of urinary deposits, blood, &c. The stand and mirror hitherto deemed essential in all compound microscopes are dispensed with. A lens is placed at the end of the microscope, which, when the instrument is held up to a window or lamp, concentrates sufficient light upon the slide to render all objects in the field distinctly visible. Even on a dull day in London we have found the illumination thus obtained amply sufficient. The microscope is a compound achromatic one, furnished with a quarter inch objective, having a magnifying power of 120 diameters, and a sliding tube of short range, for adjusting the focus. In using the instrument it is intended that a few drops of the suspected urine are placed between two small glass slides, which are then placed in a deep notch in the lower part of the microscope. They are fixed *in situ* by a sliding tube with a milled flange, which, when pushed up against the glass, holds it securely. The microscope is then applied to the eye, as shown in the engraving, and the focus adjusted.



It is an ingenious little instrument, very compact, measuring only five inches in length, and its case is scarcely bigger than that of a fair-sized urinometer. We can thoroughly commend it not only for convenience, but, when properly used, for efficiency also. It is well adapted for the examination of the blood; an excess of white corpuscles can be at once distinguished by its means. It is also, when properly employed, very useful for the examination of the urine, but used in the method recommended by Messrs. Salt, it is almost valueless for this purpose. It is true that if a urine were loaded with pus, this could no doubt be readily discovered in the manner above described; but if the urine contained a few blood-corpuscles or casts, they could not be thus discovered. The film of liquid held between two glass slides by capillary attraction is so extremely thin that objects sparingly contained in the urine would not be discovered. If, however, a small cover glass be used, and the movable tube be placed above the slide so as to clamp it from above instead of from below, and thus avoid pressing the cover glass against the edge of the notch, a thicker film of liquid is examined, and the instrument answers very well. But its utility would be greatly increased if a plain mirror were fixed in a removable tube at the end of the instrument, so that it could be used in the upright posture as well as, if desired, in the horizontal. All practitioners know how desirable it often is, in examining a urinary deposit, to have a very thick film of liquid, and this is impossible unless the microscope is vertical in position.

INSTRUMENT FOR APPLICATION OF WOOL &c. TO CAVITIES.

MESSRS. MAW, SON, AND THOMPSON have sent us a new instrument manufactured by them for the application of cotton-wool, &c. to the bottom of cavities or sinuses. It is a stout probe nine inches long, terminating at one end in two sharp prongs, which are spirally twisted. By this end cotton-wool is firmly held, and can be used to cleanse the bottom of sinuses or cavities, or, if desired, by rotating the probe in the opposite direction to the spiral, the cotton-wool is left at the bottom of the cavity. Surgeons will find it to be of use in many ways.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

THE METROPOLITAN SMALL-POX HOSPITALS AS FOCI OF INFECTION.

A LETTER, of which we subjoin a copy, is being very extensively circulated amongst medical practitioners in and about Fulham, Kensington, and Chelsea, by Dr. Thorne Thorne of the Local Government Board. The matter to which it relates is one of so much importance that we trust every one concerned will promptly comply with the request which is made.

"Local Government Board, Whitehall, Jan. 19th, 1881.

"DEAR SIR,—Under the instructions of the Local Government Board I am engaged in an inquiry relating to the use and influence of hospitals for infectious diseases, and in connexion with this investigation I am desirous of ascertaining whether such hospitals are, and if so by what means, instrumental in causing the spread of infection in the localities in which they are situated.

"At the present moment I am engaged, together with my colleague, Mr. W. H. Power, in procuring information on this point as regards the Metropolitan Asylums District Hospital at Fulham, where cases of small-pox are under treatment, and I shall feel much indebted to you if you will kindly give me the names and addresses of any persons whom you may have met with suffering from small-pox within a radius of one mile of the hospital since Christmas day last; and also if you will during the next three months give me similar information as regards any cases which may come under your notice, quite irrespective of any presumed source of contagion.

"I need hardly say that any such information will in every case be used with due regard for your own and the patient's desire for privacy.

"I am, dear Sir, very faithfully yours,
"R. THORNE THORNE."

THE DISSEMINATION OF INFECTIOUS DISEASE.

Here are some illustrations of modes in which infectious diseases are thoughtlessly disseminated. Dr. Sedgwick Saunders reports that the body of a child who had died of scarlet fever was removed from a house in Kensington to an undertaker's in the City, and kept on his premises unburied from Dec. 30th to Jan. 1st. It is reported that the corpse of a man dying of small-pox in London was carried to Cottenham in Cambridgeshire for interment. There the coffin was opened for the relatives and friends to view the deceased. As many as a hundred persons viewed the corpse, some even kissing it. Two of the relatives, it is known, subsequently were seized with small-pox and one has died. Inquiry is to be made by the Sanitary Authority (St. Ives) into the circumstances of the case and as to the extent of the mischief arising from it. The *Bucks Herald* records the following:—Scarlet fever attacks a child in a family of several children in London. The medical man recommends that the seemingly unaffected children (two) should be sent away. They were sent to an aunt in Buckinghamshire. On the evening of their arrival one was found to have the eruption of scarlet fever out upon him, the other sickened the next day. The first attacked died and an inquest was held on the body. We have still to learn whether these cases have proved the focus for a new extension of the disease.

ST. VEDAST'S CHURCH (CITY OF LONDON).

Dr. Sedgwick Saunders has presented a report to the City (of London) Commissioners of Sewers, which gives a curious account of the condition of the burial-places of the dead within this old structure. It appears that in process of time, from the deterioration of the structure of the vaults beneath the flooring of the church, the walls have yielded and cracked, the floor above also yielding, and the cracks extending through the floor into the body of the church. On an investigation of the state of the church in this respect it was found that certain builders were no better long ago than they are now, and that vaults which should have been "sealed" had not been sealed, and had been simply covered in, and even floored by old gravestones. An instance is mentioned of the wooden floor of a pew being found as constituting the only covering of a grave which contained five coffins. The congregation of the church had unwittingly for years been copying the habit of the monkish order, who are accustomed to preserve their dead and pray among them; but, unlike this order, without the corpses having undergone a previous desiccation. The Commissioners of Sewers have now taken the matter in hand with a view to secure a more decent and wholesome condition of the church.

THE POPLAR INFECTIOUS DISEASES HOSPITAL.

A deputation of the Metropolitan Asylums Board has visited and inspected this hospital, but the visit has tended to confirm the objections of the Board to either hiring or purchasing the building. Indeed, the deputation have reported somewhat disparagingly of it, averring that although the accommodation is said to have been erected for seventy-two patients, in reality it is only sufficient for forty-eight; and, in addition, they assert that the arrangements for the executive are deficient. For example, room is wanting for lodging servants. The Poplar District Board thought it bad enough for the Asylums Board to refuse to come to terms with them, but for the latter to depreciate the hospital, a brand-new one built at a considerable cost, is more than District Board nature can bear; so a "representation" is to be made to the Asylums Board concerning the injurious remarks of the deputation.

THE RURAL SANITARY AUTHORITY OF GUILDFORD.

We are glad to learn that the Rural Sanitary Authority of Guildford have decided that it is no longer desirable that the medical officers for the Union be reappointed medical officers of health, but that one medical officer of health who is not in private practice be appointed. We trust the Authority will further see the advantage of entering into the Surrey Combination of sanitary districts for the appointment of a medical officer of health. The evidence in favour of combined districts for such appointment would appear from the latest report of the Local Government Board to be almost overwhelming, and Guildford is so situated with respect to the Chertsey Union, Dorking Union, &c., as to appear to fall naturally into combination with them. We have little doubt that this view of the subject will receive the full consideration of the Authority.

The vaccination officer of Bethnal-green has asked his Board of Guardians for assistance to make a house-to-house visitation of his district, small-pox being still on the increase there. One member thought the request to be much too serious to settle offhand, and that it should be referred to the Dispensary Committee. Another thought that this talk about small-pox was "sheer nonsense." The disease was "simply nature righting herself." A third thought twenty assistants would be needed to do the work thoroughly which the vaccination officer wanted to be done (not seeing that the statement was a confession of the backward state of vaccination in the parish). A fourth thought that it would be unwise "to employ such a large staff without due consideration." So (the Local Government Board's advice notwithstanding) the Board of Guardians will pause to consider a question which ought to have been "considered" months ago, while small-pox steadily gains ground.

Dr. Bridges has been complaining to the Local Government Board of the physical condition of certain children in St. Olave's Workhouse. The Local Government Board transmitted Dr. Bridges' observations to the Board of Guardians. In their discussion of these observations, the Chairman of the guardians observed that the questions raised by Dr. Bridges had been considered by the visiting committee, and the statement with respect to insufficient dietary only related to a few of the elder children. Whereupon a Guardian observed that doubtless by the summer time St. John's churchyard would be in a condition to be used by the children. Does this mean for burial or for exercise?

An evening contemporary announces that, on the recommendation of the Metropolitan Asylums Board, the visiting of relatives and friends to the inmates of the metropolitan workhouse district schools and orphanages in connexion with the Poor-law administration has been prohibited in consequence of small-pox in the metropolis. Does this imply that the Metropolitan Asylums Board distrust the protective power of vaccination, or that the children in the orphanages and schools are imperfectly vaccinated? We commend the question to the attention of the Local Government Board.

We understand that the St. George's-in-the-East Vestry, as Sanitary Authority, has felt called upon to require the Blackwall Railway Company to *clean* its station at Shadwell, the persistent dirtiness of the stations on this line of railway not hitherto having been interfered with. The Company are aghast at this astounding interference with a right of uncleanliness which they had reason to believe had become vested by long immunity.

On a question of giving additional remuneration to the relieving officers for extra services in connexion with the vaccination work of the Union, before the Stepney Board of Guardians, several members spoke in forcible terms of the neglect of vaccination in the Union, and of the vaccination work of the guardians having been suffered to fall into arrear.

The Crewe magistrates have imposed a fine of £4 on a pork-butcher for keeping his premises in an uncleanly state, surreptitiously passing offal into the drains of his slaughter-house, not having provided proper receptacles for it.

The Court of Chancery has refused to enforce the specific performance of certain contracts for the purchase of dwelling-houses in which the drainage was found to be defective.

The report of a serious outbreak of scarlet fever having occurred in the neighbourhood of Lincoln is, we understand, incorrect.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

The effect of the severe cold which set in on 12th inst. caused a marked increase in the registered mortality last week, although the increase was scarcely so great as might have been expected to result from the exceptionally low temperature recorded. In twenty of the largest English towns, estimated to contain in the middle of this year a population exceeding seven and a half millions of persons, 4582 births and 4199 deaths were registered last week. The births were 604 below, whereas the deaths exceeded by no less than 904, the average weekly numbers during last year. The deaths showed a further increase of 755 upon the low numbers returned in recent weeks. The annual death-rate, which had been equal to 21·3 and 23·6 in the two preceding weeks, further rose last week to 28·8, a higher rate than has prevailed in any week since the first week in February last, when it was equal to 37·0. During the past three weeks of the current quarter the death-rate in these twenty towns averaged 24·6 per 1000, and was 0·9 below the average rate in the corresponding periods of the five years 1876-80.

The deaths referred in the twenty towns to the principal zymotic diseases, which had been 401 and 383 in the two preceding weeks, were 390 last week, and included 103 from scarlet fever, 93 from whooping-cough, and 72 from measles. The annual death-rate from the principal zymotic diseases averaged 2·7 per 1000 in the twenty towns, among which it ranged from 0·7 and 1·0 in Wolverhampton and Hull, to 3·6 and 4·0 in Norwich and Salford. Scarlet fever showed the largest proportional fatality in Norwich and Sunderland, whooping-cough in Leeds and Nottingham, and measles in Salford. The deaths referred to fever (principally enteric) in the twenty towns, which had been but 39 and 35 in the two previous weeks, further declined to 32 last week, and were very considerably below the average. Nine of the 13 deaths from diphtheria occurred in London. Small-pox caused 44 more deaths in London and its suburbs, whereas no fatal case of this disease was registered in any of the nineteen large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylum Hospitals, which had steadily increased from 77 to 477 in the twelve preceding weeks, further rose to 516 on Saturday last. The new cases of small-pox admitted to these hospitals, which had been 85 and 118 in the two preceding weeks, further rose to 142 last week. The Highgate Small-pox Hospital contained 27 patients on Saturday last, against 24 and 26 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had slowly increased from 290 to 371 in the four preceding weeks, rose last week, under the influence of the severe cold, to 617, and showed an excess of 141 upon the corrected average number in the corresponding week of the last ten years; 441 were referred to bronchitis, and 97 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 8·7 per 1000 in London, while the rate from the same diseases was 14·2 in Liverpool.

In the twenty towns last week the causes of 114 deaths were not certified, either by a registered medical practitioner or by a coroner; these were equal to 2·7 per cent. of the total deaths. The proportion of uncertified deaths was equal to 1·8 per cent. in London, while it averaged 3·6 per cent. in the nineteen provincial towns. The proportion of uncertified deaths was largest last week in Salford, Sheffield, Bradford, and Hull.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 31·1 per 1000 last week, against 22·5, 25·9, and 24·6 in the three preceding weeks; this rate exceeded by 2·3 per 1000 the average rate last week in the twenty large English towns. The rates in the eight Scotch towns ranged from 21·4 and 27·2 in Edinburgh and Aberdeen, to 35·5 and 38·1 in Glasgow and Paisley. The deaths referred to the principal zymotic diseases in the eight towns, which had been 105 and 102 in the two preceding weeks, were 107 last week, and were equal to an annual rate of 4·2 per 1000, against 2·7 in the twenty large English towns. In the eight Scotch towns the zymotic death-rate last week ranged from 2·1 and 3·0 in Paisley and Aberdeen, to 4·7 and 6·9 in Edinburgh and Leith. The fatal cases of scarlet fever in the eight towns, which had been 27 and 19 in the two previous weeks, were 28 last week, of which 10 occurred in Edinburgh, 10 in Glasgow, and 6 in Leith. The 25 deaths from whooping-cough showed an increase of two upon the number in the previous week, and included 15 in Glasgow, 5 in Edinburgh, and 4 in Dundee. Of the 19 deaths from diphtheria 12 were returned in Glasgow, as were

8 of the 12 fatal cases of measles in the eight towns. The 8 deaths referred to "fever" showed a decline of 7 from the number in the previous week; 2 occurred in Glasgow, 2 in Edinburgh, and 2 in Greenock. The deaths referred to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), in the eight Scotch towns were 307 last week, against 161 and 191 in the two previous weeks; they were equal to an annual rate of 12·2 per 1000 of the population; the death-rate from the same diseases in London did not exceed 7·6. The greatest fatality from lung diseases in the Scotch towns occurred last week in Glasgow, Dundee, and Paisley.

HEALTH OF DUBLIN.

The rate of mortality in Dublin showed a further increase last week. The annual rate of mortality from all causes in the city, which had been equal to 31·8 and 35·1 in the two preceding weeks, further rose last week to 45·7, a higher rate than has prevailed since the end of January last. During the first three weeks of the current quarter the death-rate in the city averaged 37·5 per 1000, against 24·1 in London and 23·2 in Edinburgh. The 292 deaths in Dublin last week showed a further increase of no less than 68 upon the numbers returned in the two preceding weeks, and included 37, or nearly 13 per cent., which were referred to the principal zymotic diseases; against but 12 in the previous week. These 37 zymotic deaths in Dublin last week included 17 which were referred to fever (typhus, enteric or typhoid, and simple continued), 8 fatal cases of whooping-cough, 6 of scarlet fever, 3 of diphtheria, and one each of small-pox, measles, and diarrhœa. The annual death-rate from these zymotic diseases was equal to 5·8 per 1000 in Dublin last week, while it did not exceed 2·9 in London, and was 4·7 in Edinburgh. The deaths referred to fever in Dublin, which were 13 and 8 in the two previous weeks, rose to 17 last week, and were equal to an annual death-rate more than twelve times as high as the average rate from the same causes last week in the twenty large English towns. The eight deaths from whooping-cough also showed a marked excess upon recent weekly numbers, and the deaths from scarlet fever were within one of those returned in each of the two previous weeks. The deaths of infants were more numerous, but the largest proportional increase occurred among elderly persons; the deaths of persons aged upwards of sixty years, which had been 47 and 66 in the two previous weeks, further rose to 84 last week.

VITAL STATISTICS OF THE ISLE OF MAN.

Civil registration in the Isle of Man was, by recent legislation, nearly assimilated to that which has long prevailed in the rest of the United Kingdom, and the figures for the year 1879 for the first time afforded facilities for comparison and estimation of sanitary condition. The Isle of Man has an area nearly half as large again as that of Rutlandshire, and had in 1871 a population of 54,042, more than twice the population of that county; assuming that the population of the island since 1871 has increased at the same rate as that which prevailed between 1861 and 1871, the present population may be estimated at 55,653. During the year 1879 the births and deaths registered within the island were, respectively, 1569 and 1122, calculated upon the estimated population in the middle of 1879, the birth-rate was equal to 28·3, and the death-rate to 20·2 per 1000 persons living. The marriage rate was equal to 12·4 per 1000. Both the marriage and birth-rates were below the average rates in agricultural counties in England. It may be noted that 7·2 per cent. of the births registered were those of illegitimate children. The death-rate in the Isle of Man differed but slightly from the average rate in England and Wales in 1879, which was 20·9 per 1000. The fatality from the principal zymotic diseases, however, was remarkably small in the Isle of Man, as only 39 deaths in 1879 were referred to measles, scarlet fever, diphtheria, whooping-cough, enteric fever, and diarrhœa, and none to small-pox, typhus, or simple and undefined fever. The annual death-rate from these principal zymotic diseases in the Isle of Man during 1879 did not exceed 0·7 per 1000, against 2·4 in England and Wales. The low rate of infant mortality in the island also affords satisfactory evidence of its sanitary condition; the proportion of deaths under one year of age to births registered in 1879 was not quite equal to 105 per 1000, whereas the average proportion in England and Wales was 136 per 1000. One unsatisfactory feature in the figures for the year may be noted, and this is a high rate of puerperal fatality. We have said that 1569 births were registered in the island during 1879, and it appears that sixteen deaths occurred in childbirth, including five from puerperal fever; these show a rate of puerperal fatality equal to 10·2 per 1000 children born alive. In England and Wales the average proportion of deaths of mothers to 1000 children born alive did not exceed 3·8 during the three years 1877–8–9. It may be hoped that the rate of puerperal fatality in the Isle of Man during 1879 was exceptional. As the death-rate from zymotic diseases in the Isle of Man was so much below, and the rate from all causes differed so little from the rates in England and Wales, it follows that an excess must have occurred from some other causes; but from what diseases this excess mainly arose does not appear from the return before us. It may be noted, however, that the death-rate from phthisis and from acute diseases of the respiratory organs was equal to 3·4 and 3·1 per 1000 of the estimated population; both these rates were in excess of the average English rates from the same diseases. These statistics, if continued annually, will afford the best possible test of the varying sanitary condition of the Manx population.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DIPHTHERIA.

The continued attention which is being given by medical officers of health to diphtheria is interestingly indicated by two communications which have recently reached us. The one is an inaugural address delivered before the Birmingham and Midland Society of Medical Officers of Health by Mr. G. H. Fosbroke, medical officer of health for the urban and rural sanitary districts of Stratford-on-Avon, Evesham, and Alcester, President of the Association; the other contains brief "Notes on the Spread of Diphtheria," printed for private circulation by Dr. Edwyn Slade-King, medical officer of health for Torrington, Ilfracombe, and Dulverton. Mr. Fosbroke devoted his address chiefly to an account of the experiences he had had of diphtheria in his district, comparing these experiences with those of other persons with reference to the disease, and laying particular stress upon the greater prevalence of the malady in rural as compared with urban districts, its association with typhoid fever and with scarlet fever, which he holds to be much closer than is commonly believed, and its inaptitude, as he thinks, to extend in towns as contrasted with the country. Further, he expressed himself as having been unable to trace any definite relations between the prevalence of the disease and the geological formation of a locality, or between the fluctuations of the malady in a district where it was long prevalent and season; he commented on family susceptibility as a predisposing cause, and finally confessed that he had felt himself compelled to admit the spontaneous origin of the disease in certain cases. Dr. Slade-King holds the opinion that "the atmosphere becomes contaminated by contagia from the bodies of the sick [of diphtheria], and that currents of air carry the poison with them in their course"; and he relates several very curious and instructive outbreaks of the disease within his district of particular interest to the student of diphtheria.

SCARLET FEVER AT ROSENEATH AND CLYNDER.

An alarming outbreak of scarlet fever has taken place at Roseneath and Clynder, on the shores of the Gareloch. Many of the cases are serious, and several deaths have already been reported. The drainage of the whole district is extremely unsatisfactory; between the Glasgow sewage mud, brought down and deposited with each tide, and the local sewage, which is discharged usually between high and low-water marks, this locality, which was and is still a favourite summer retreat, is fast becoming unbearable. It is now difficult to find on the shores of the loch a clean spot for bathing; while the local smells and the frequent endemic prevalence of "influenza" are scaring off summer visitors. It is said, however, that the authorities are arranging a complete drainage system for the district, under the guidance of Dr. Yair. Perhaps this epidemic may give an impetus to their efforts. In connexion with this matter, the Rev. Dr. Story, at the close of a recent Sunday service, addressed some plain and sensible observations to his congregation. While regretting the distress prevailing in the parish, he advised the people not to give way to a feeling of panic, but to do all in their power to avert the threatened evil from themselves and their families. He counselled them to keep their houses clean both inside and outside, to clothe their children as warmly as possible, and to give them plain wholesome food, and no trash.

THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.

The annual meeting of this Association was held on the 18th inst., the Bishop of Manchester presiding. We regret to see that the financial condition of the society is still not so prosperous as it should be in so wealthy a city as Manchester. It is a poor return for the benefits that this society has conferred upon the borough, and upon the sister borough of Salford, in keeping public attention alive to the importance of public-health questions, that it should be straitened for funds. A want of just recognition of the educational influence exercised by the Association in matters of health is here implied which is somewhat dispiriting. We also regret to see that from the increasing difficulties the Association has experienced in collecting records of sickness the weekly returns it has issued for twenty years have now to be given up. Considerable attention was devoted during the meeting to the excellent educational work of the Ladies' Branch of the Association.

Dr. Russell of Glasgow reports the occurrence of twelve cases of typhus among persons who had attended the "wake" of a man who had died of the disease in his own residence.

THE SERVICES.

Surgeon-Major R. W. Davies, Army Medical Department, has been appointed surgeon on the personal staff of Sir Donald Stewart, G.C.B., the new Commander-in-Chief in India.

Surgeon-Major James Hector, M.B., has been appointed to the medical charge of the 13th Hussars at Candahar.

Surgeon Henry Bradford, A.M.D., has been appointed Instructor of the Army Hospital Corps, Aldershot, vice Surgeon-Major T. Faris, who has proceeded on service to Natal.

ADMIRALTY.—The following appointments have been made:—Staff-Surgeon C. Harvey to the *Triumph*, for Esquimalt, sick quarters, vice Sharood; Surgeon H. B. Guppy to the *Ganges*, vice Fisher.

THE CASE OF LOUISA MORGAN

(GUY'S HOSPITAL).

THE following is the "Clinical Report" of this case, to which reference was made in the proceedings.

Ward and No. of bed: Mary, No. 2. Nature of case: Old and quiescent phthisis; suppurating cyst in broad ligaments; acute inflammatory mass (tubercular) in cortex of brain. Result: Death; tubercular meningitis. Name and age of patient: Louisa Morgan; aged twenty-six. Residence: 42, Charlotte-street, Old Kent-road. Date of discharge: Died July 21st, 1880.

Physician: Dr. Pavy. Clinical clerk: J. R. Veitch. Date of admission: June 9th, 1880.

Occupation.—Has been in the habit of working the sewing-machine. Is married; has been married ten years; has one child nine years old; never had a miscarriage.

Family history.—Parents both dead. Father was between fifty and sixty when he died. Does not know what he died of. Mother died of brain trouble, aged fifty. No history of phthisis in the family.

Personal history.—Had scarlet fever and measles when a baby. Seven years ago had gastric fever, for which she had medical advice for nearly two months. Has always had a slight cough in winter, but the last winter it was much worse than usual. Has lived regularly; accustomed to take beer and sometimes spirits with her meals. Ten years ago suffered very much from rheumatism in her arms and shoulders principally; was unable to use her arms without great difficulty. Does not remember any particulars of her illness.

Present illness.—Last September had great pain in the lower part of the abdomen; also great pain in her back and loins; was unable to take her food, but suffered from continual thirst. When she drank much she immediately suffered from diarrhœa, with great pain, and passed very light motions. The pain extended down her left thigh; was attended by Dr. Palmer for four months. She remained in bed for about a month, and then began to get about a little each day, but not for any length at a time on account of pain in her stomach and back. She got very much better, and remained so until February, 1880, when she was again taken ill. Was advised to come into the hospital. Three weeks ago her feet and legs began to swell from the ankle to the knee. The diarrhœa was bad, and she suffered from pain in her stomach and back.

Personal appearance.—Thin, delicate-looking, anæmic; complexion light; anxious expression; eyes light, pupil contracted; skin thin, hot, and moist.

Alimentary system.—Tongue clean; appetite bad; complains of great thirst, nausea, and sickness; motions not regular, and very light in colour.

Circulatory system.—Normal.

Respiratory.—There is slight bronchial breathing at the left apex.

June 9th.—Chop.—11th: Evening temperature, 100·4° F. Patient complains of severe headache; her breathing is regular and easy. Takes her food well. Bowels lax.—12th: Evening temperature 99·8°.—14th: Milk O. ½, soda water, and six ounces of wine; ferri am. cit., gr. 5; tinct. sumbul, min. 20; mist. am., ℥ 1; t.d.s.—16th: Still complains of headache; says it is worse after taking her medicine. A harsh sound is heard at the left apex. Appetite is not so good to-day; tongue rather furred, whitish-brown. Bowels open.—20th: Headache is rather less than it was, but still complains slightly.—25th: Headaches have left her, but she complains of pains in her back and loins; has a leucorrhœal discharge; takes her food well; pulse strong; breathing just the same as before; the bronchial breathing is still heard just below the angle of the scapula (left).—30th: Patient still the same; no headache, but pain in the back and loins. Discharge still continues.

[Note by the Registrar for July 5th.]—I saw her about two hours after bath. At first sight I thought her moribund. She was utterly collapsed, blue and cold. She took no notice of anything about her, and would not answer questions.—F. A. M.

July 6th.—Patient is much worse this morning. Yesterday had a very prolonged bath, almost cold water; remained in it for a considerable time; appears to have suffered from a severe mental shock. (Dr. Pavy.) There was considerable bruising over left shin, and several slight bruises on both arms.—7th: Patient still in same condition. Does not care to answer questions. Tongue furred, brownish colour; face much flushed. There is a nervous twitching at the bedclothes. Passes everything under her. Evening temperature 100·8°; pulse 120.—8th: Morning temperature 99·4°; evening temperature 101·4°.—9th: Still the same objection to speaking; lies quite still except for the twitching of the hands. Takes her food well when she is fed. Morning temperature 100·2°; evening temperature 101·2°; pulse 116; respiration 40.—11th: Morning temperature 99·2°; pulse 100; respiration 38; evening temperature 101·6°; pulse 120; respiration 40.—12th.—Slight bronchial breathing still heard at left apex, just below left of scapula. Does not answer questions; refuses to put out her tongue. Skin very hot, moist. Cheeks much flushed. Passes everything under her. Morning temperature 102·4°; evening temperature 102·6°; respiration 36; pulse 130.—13th: Mist. chinchon. co., ℥ 1, t. d. s. Morning temperature 102·4°; pulse 140; respiration 38; evening temperature 104° (10 P.M.); pulse 150; respiration 48.—14th: Enema saponis stet. Morning temperature 103·6°; evening temperature 102·4°; pulse 140; respiration 32.—15th: Still the same; temperature very high; appears hardly sensible; P. enema. Morning temperature 102·4°; evening temperature 103·2°.—16th: Glyc. boracis. Morning temperature 101·4°; pulse 150; evening temperature 103·2°; pulse 150.—17th: Patient still lying in a semi-conscious state; will not take food unless put into her mouth. Morning temperature 103·2°; evening temperature 102·6°; pulse 140.—18th: Morning temperature 102·6°; pulse 140; respiration 40.—19th: There is bronchial breathing at apex of right scapula; patient still in same condition. Morning temperature 104°; evening tem perature 104°; pulse 146.—20th : Patient perfectly unconscious ; appears to suffer acute pain when left arm is lifted in taking temperature ; swallows with difficulty. Morning temperature 105°; evening temperature 104·7° ; pulse 200 ; respiration 60.—21st : Morning temperature 105°; pulse 200; temperature 106° (2 P.M.)—22nd : Patient died at 11.30 last night. Post-mortem examination to-day.

The following is a summary of Dr. Goodhart's notes of the post-mortem examination :—

Post-mortem.—The convolutions of the right hemisphere along the longitudinal fissure, about the hinder part of the first frontal and the anterior central, were involved in a large mass of yellow tubercles, which dipped some way into the white matter of the cerebrum. The section of it was of an unusual appearance, being softer than usual and many-coloured, from changes in the blood pigment within and around it. At first sight it was not unlike a mass of red softening. But a more careful examination showed that it was a focus of yellow tubercle, in which other secondary changes, softening, and decomposition, or disintegration of blood had occurred. Behind this large mass was a second smaller one, also in the convolutions, bordering the longitudinal fissure, and having the usual fine yellow characters of yellow tubercle. In addition to these, the convolutions about them had a diffused layer of yellow tubercle uniting their edges, and spreading into the pia mater over them, while at the base there was a general tubercular meningitis. It was my opinion at the time that there had been a quiescent or slowly-maturing growth of yellow tubercle, probably existant for some time, and that the softening and tubercular meningitis were of recent date.

Correspondence.

"Audi alteram partem."

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.

To the Editor of THE LANCET.

SIR,—As a licentiate of the above College I have been extremely pleased with the letters in your journal. At the same time I must say that it is somewhat extreme to designate the Fellowship of this college as a *bogus* diploma. No one can obtain it who has not passed an examination in surgery previously. You might as well say that the M.D. degrees of St. Andrews and Aberdeen are bogus degrees; still, I think no one will be bold enough to assert this. These degrees are given by promotion, after the M.B. has been two years in practice, which really means nothing, for a practitioner may be unfortunate enough to see very little practice in two years, or, may be, he practises homœopathy during that period. Edinburgh and Glasgow have only insisted on a *thesis* for the degree during the last few years, and a few years ago it was very seldom a thesis was rejected. It must, however, be remembered that they only promote their own graduates, and it is here where the Edinburgh College has sinned. It should only have promoted its own licentiates. If it had done so we should not have had this outcry.

I do hope, however, that good may come out of this adverse opinion as to the granting of the Fellowship, and hope the Edinburgh College will see its way to institute an examination for its higher qualification, even at the expense of another charter. If it cannot do this, then why not do like the university, have a thesis on a surgical or scientific subject, and also limit the promotion to its own licentiates? It would then compel aspirants to be examined, although they might have some other surgical diploma; and from what I know of the licence of the College, I can say that the examination will bear comparison with any of the other corporate, and even some of the university, examinations. One of your correspondents seems to make light of the examination for the licence; evidently he is newly fledged, or is not even tolerably acquainted with older surgeons who possess *only* the licence of the Edinburgh College as qualifying for practice. When I was a student, a few years ago, men were rejected who a few weeks after were capped for the degree of M.B. The older licentiates, however, will tell you that the Edinburgh College was, as it is now, with the exception perhaps of one or two corporations, the only college which gave a *complete* examination in all branches of medical science, and this certainly is a great thing to say, when we find our London College only *now* taking steps to do the same.

I am, Sir, yours, &c.,

Wigan, Jan. 24th, 1881. WM. BERRY, M.R.C.S. Eng., &c.

To the Editor of THE LANCET.

SIR,—Are you aware that the R.C.S. Edinburgh have had for some time under consideration a scheme for examination for its Fellowship?

I applied about three months since for admission (under examination), having seen that some of the "Fellows" placed the magic words "exam." after their names. I was in reply informed that this was under an "old" statute, and that I could only be admitted under the existing rules, but that they hoped very speedily to promulgate some new ones for holding examinations similar to the English College.

I think this should be generally known, and I should feel obliged if you would give this the same prominence as other letters upon this subject, in justice to the Edinburgh College of Surgeons, who have intended altering the present state of affairs, prior to your justly-merited leader upon the sale of "highest" diplomas.

I am, Sir, yours faithfully,
ARTHUR PRICE, M.R.C.S. Eng., &c.

Great Smith-st., Westminster, S.W., Jan. 25th, 1881.

STATISTICS OF OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—At the meeting of the Royal Medical and Chirurgical Society, to which Dr. Bantock refers in his letter of Jan. 15th, I entered a strong protest against the system of rediscussing in the journals papers which have been fully discussed before the Society. This is my reason for keeping silence under the battery of letters with which we have been edified, and in which my work has received its full share of attention. I intend to adhere to my resolution. When I have fresh facts to bring forward I shall publish them, and do not fear the verdict of the profession. Having written so many letters, Dr. Bantock is naturally in doubt as to which of them I referred to. The reference was to one which appeared in the *Medical Times and Gazette* in August last.

A suggestion has been made that a committee should be appointed to watch the results of Listerian and non-Listerian ovariotomy. I think the suggestion a good one, and if an impartial committee can be formed I shall not only be happy to facilitate their observations on my future practice, but shall be glad to give them access to all my case-books since I commenced abdominal section.

I am, Sir, truly yours,
J. KNOWSLEY THORNTON.

Park-street, Grosvenor-square, W., Jan. 26th, 1881.

THE NEW FORM OF GAG.

To the Editor of THE LANCET.

SIR,—Will you allow us to state that the "improved" ring-catch with notches, for which Messrs. Mayer and Meltzer claim credit, was the original form as made by us for Mr. Rose? The serrations, however, were found to do more harm than good, as they were apt to jam the operator's fingers and pinch the patient's face, as well as to prevent the ready adjustability of the instrument. They were therefore abolished, and the requisite fixation secured by "draw-filing" the opposing surfaces.

We were under the impression that Messrs. Mayer and Meltzer were aware of this, as we find in their Catalogue, Fig. 431, a woodcut of a double-ended gag, *with* the serrations now claimed as original, described as "W. Rose's double-ended gag." It is not for us to go into the question of the advantages or disadvantages of tongue-plates, but our experience as instrument makers has been in conformity with the wishes of our customers, to use them as little as possible. Indeed, the gags constructed by us for the late Sir W. Fergusson, Mr. John Wood, Mr. Francis Mason, and Mr. W. Rose, have been especially designed with the view of getting rid of tongue-plates altogether.

We remain, Sir, your obedient servants,
MATTHEWS BROS.

Carey-street, W.C., Jan. 24th, 1881.

MANCHESTER.

(*From our own Correspondent.*)

ON Wednesday last an experimental meeting of the Medical Society was held in the Memorial Hall, Albert-square, the outcome of a feeling amongst some of the members that a more centrally situated place of meeting should be provided than Owens College, where the Society's meetings have hitherto been held. The meeting was very well attended, and the cases presented were of unusual interest. The general feeling of the members, however, seemed to be that the very desirable advantages of the central position and greater accessibility of the new room were rather marred by its bad lighting and general dinginess. In this connexion we may mention that it has long been the earnest desire on the part of the medical profession here that our magnificent library should be housed in a building actually situated and specially designed for the purpose, and which would contain spacious rooms for holding the monthly and other meetings of the Medical Society. This scheme, however, has never been properly set on foot, owing to the large expenditure such an undertaking would entail.

A nucleus for a building-fund has just unexpectedly been formed by the generous donation of £150 by Dr. Humphreys, who, when he was with us, always took a lively and practical interest in the welfare of the Society. This sum was the amount (with a small addition by Dr. Humphreys) subscribed by the medical profession here as a slight token of the sympathy felt for him on his leaving Manchester. It is to be hoped that the small beginning will grow, and act as an example for others to do likewise, until a fund is established which will provide for the erection and maintenance of a building worthy of the medical profession, the medical library, and an ornament to the city.

The Edinburgh University Club had its annual gathering on Friday last at the Queen's Hotel, when forty-six members sat down to a most *recherché* dinner. The chair was occupied by Professor Gamgee of Owens College. The usual loyal toasts were proposed, and some excellent speeches were delivered on the occasion, the proceedings being enlivened at intervals by songs of a national character. It was a noteworthy feature of the meeting that no reference was made either to Robert Burns or Dr. Chalmers—a circumstance probably unparalleled in the history of Scottish assemblies.

I now pass to the consideration of a more serious subject and one more intimately bound up with the interests of the coming race of medical practitioners. I wish to draw attention to the great mass of good educational material which is going to waste in our midst. We have *inter alia* three large medical charities devoting themselves to the treatment of special diseases—viz., the Children's Hospital, Pendlebury, the large Gynæcological Hospital of St. Mary, and the Royal Eye Hospital, second only in size to Moorfields, institutions which draw their patients from the teeming population of the surrounding manufacturing districts. These charities are officered by men of capacity, undoubted talent, and teaching power, but the number of students who avail themselves of their privileges is very small. This may arise from a variety of causes. Pendlebury Hospital can never by its position (four miles from the town) become a teaching centre; the other two hospitals are, however, centrally placed, and close to one another. The student of to-day may be over-lectured and over-examined, but he incurs a serious responsibility should he commence practice without a good knowledge of special subjects, which can only be adequately obtained in hospitals where large numbers of selected cases can be brought under his observation. Be the causes what they may, I am certain that a vast impetus would be given to the diffusion of special medical knowledge were these institutions recognised in some way by the licensing boards, either by accepting certificates, or otherwise. A stimulus of this sort is wanted to make the medical officers take the initiative in the formation of clinical classes, in which work they would no doubt have the hearty co-operation of their respective boards of management.

However, it is certain that something should be done, and that speedily, to instil life into the project, and thereby open up these vast storehouses of practical experience and knowledge. To this important subject I will return on a subsequent occasion, when I shall be fully armed with statistics to support my thesis.

EDINBURGH.

(*From our own Correspondent.*)

AT one of the recent Health Lectures for the people some interesting statistics of infant mortality were given from reports furnished by Dr. Littlejohn, the medical officer of health. In the New Town the death-rate was 18 per 1000, the mortality above five years of age was 13 per 1000, that below five years was 67 per 1000. In the Old Town the mortality was 30 per 1000; above five years 19 per 1000, under five years 108 per 1000; while in certain localities of the Old Town the mortality was specially great, as, for instance, in the Grass market, where the mortality reached 137 per 1000.

The general meeting of the infirmary contributors was held in the City Chambers on the 10th inst. The report presented stated that the experience of the first year's occupation of the new infirmary had been highly satisfactory. It was found that on contrasting the expenditure of the past year with that incurred in the old building, say in 1878, when about a similar number of in-door patients were treated, the increase amounted only to £2688; and it was stated that the managers were taking steps to manage the heating and lighting in a more economical manner. The additional accommodation for students in the clinical lecture rooms has been supplied, and the expense has been already covered by the students' fees. Attention was also drawn to the fact that infectious cases were not treated in the new building, and it seemed to be the opinion of many present that a separate fever hospital should be established, since the revenue of the present infirmary did not admit of the support of such an institution. The suggestion that the Local Authority should purchase the old hospital for the benefit of the city, using part of it for paying patients, or for various sanitary purposes, and so being prepared for epidemics, was favourably received.

Mr. Spence lately trephined in a case where inflammatory symptoms appeared after an injury. On dividing the dura mater pus escaped. The patient is doing pretty well, but has become aphasic.

MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Thursday, the 20th inst., a petition was presented from Surgeon Malachi O'Dwyer, for redress of grievances in connexion with the Medical Service of the East India army. The second reading of the Medical Appointments Qualification Bill was deferred to Tuesday. A Bill to amend the law relating to coroners in Ireland was brought in by Mr. Healy, Mr. Gray, and Mr. Barry, and put down for second reading on Friday, 28th inst. Mr. Litton gave notice that he would ask leave to introduce a Bill to extend to Ireland some provisions of English and Scotch law as to the care of lunatics.

On Friday a further petition *re* the East Indian Army Medical Service was presented from Surgeon W. A. Manson for redress. On the motion of Mr. Pell returns of pauperism were ordered for every English county.

On Monday Mr. Barclay put a question with regard to the scheme for reconstructing Gordon's Hospital, Aberdeen, which Sir W. V. Harcourt was unable to answer, owing to the absence from London of the Lord Advocate. A Return was ordered of the report of a recent Poor-law Inspector's inquiry at Dromore Workhouse. Mr. Litton brought in his Irish Lunatics Bill, which was read a first time. The names on the back of the Bill are those of Mr. Findlater, Sir Thos. McClure, and Mr. Litton. A petition was presented from Samuel C. Amesbury for inquiry into the East India Medical Service. A return was ordered of a recent inquiry at Belfast Workhouse.

On Tuesday Sir H. Maxwell asked the President of the Board of Trade what steps, if any, were being taken, or contemplated, in order to protect British producers from unfair competition, caused by the importation from America of spurious compounds resembling, and in many cases sold to and by retail dealers as butter; and whether, in view of the rapidly increasing exports of oleomargarine, sulne, soapstone, &c., from America to Holland, and the rapidly increasing exports of dairy produce by the latter country to this country, any safeguards were maintained against the importation of such spurious compounds from Holland. Mr. Chamberlain said the subject had been for some time past engaging the careful attention of the Board of Trade, and very recently, as the hon. baronet might have seen, a paper had been printed and circulated which gave a considerable amount of information with respect to the manufacture of those compounds. It would appear from the statements of experts that in the majority of instances those manufactured butters were not unwholesome; and, under those circumstances, it was difficult to see how their importations could be prohibited. At the same time it was, no doubt, very desirable for statistical and other reasons that they should be imported under their right names. The hon. bart. referred in his question to cases in which he said those compounds had been sold to and by retail dealers as butter. He could only say in those cases that he imagined the Adulteration Act would afford a remedy for such malpractices. Sir H. Maxwell asked if the right hon. gentleman was quite sure with regard to the wholesomeness of the compounds. Mr. Chamberlain said he did not speak from personal experience in the matter, but merely from the reports furnished to him. Sir A. Gordon gave notice of a question for Friday as to famine in Southern Afghanistan, and Mr. Parnell gave notice of an inquiry as to "distress and misery" in Kanturk Union Workhouse. Mr. Warton gave notice that he will move the rejection of the Coroners (Ireland) Bill.

The usual Wednesday sitting of the House did not take place, owing to the "all night sitting" of Tuesday.

On Thursday Mr. Shaw Lefevre was questioned as to his refusal to allow snow from the streets to be carted into the parks, and gave as his reason that it spoilt the grass.

Obituary.

NATHANIEL HENRY CLIFTON, F.R.C.S. ENG., J.P., ISLINGTON.

SOME practices are the creation of one man. A larger number represent a principle of continuity, not to say heredity. The name of Mr. Clifton carries the people of Islington back more than a hundred years. And yet over all this time a large section of the people of Islington have enjoyed the privilege of being attended by Mr. Clifton or his immediate ancestors. It is not the least credit of the family that for this more than century of work only three successive members of the family have been necessary. The subject of our present notice was wont to tell how his grandfather took up his abode, lodging with a worthy baker, in Cross-street, Islington, over a hundred years since. Mr. Clifton's grandfather was born in 1751, and was in practice before 1778. He died in 1822 in Cross-street, and was succeeded by his son Nathaniel Clifton, who was born in 1786, and died in 1861 — all in Cross-street. Here too Mr. Nathaniel Henry Clifton was born Nov. 29th, 1818, and here, we are sorry to have to tell, he died on Friday, Jan. 21st, 1881, in his sixty-third year. There is an element of permanence, a faithfulness to groove and place, in most good families which is not to be unnoted. Cross-street, as it exists now, may not seem to passers through a romantic spot, to which to fix one's existence, but to a man of Mr. Clifton's character, with its historical baker's shop, which, by the way, still, we believe, survives, it had a claim and a charm to which the new-built villa has no pretensions.

Mr. Clifton was educated at the Charterhouse and at the Proprietary School, Islington. He entered Bartholomew's Hospital in 1837. He was made a governor of the hospital then or soon after. Subsequently he was put on the House Committee, and for thirty or forty years continued to take a very active personal interest in the work.

Mr. Clifton's character was one that compelled the respect of men of all parties, and especially of members of his own profession, by whom he was looked up to as a guide and friend in circumstances of difficulty and in questions of conduct. He himself was a model ot professional behaviour. His benevolence took varied and quiet forms, and will be greatly missed, not least by many who enjoyed, for little or no pecuniary consideration, his continuous and careful professional attendance. The Islington Dispensary, the Medical Benevolent College, and other kindred institutions, lose by his death a cordial supporter. He was for many years treasurer of the Islington Savings Bank, of which his father was one of the founders.

Himself a Conservative and an active member of his party, Mr. Clifton could conduct his political or even ecclesiastical contests without acerbity. So high did Mr. Clifton stand in public estimation, that a few years ago he was made a Justice of the Peace for Middlesex, a position in which his professional judgment and his long and extensive knowledge of the district stood him in good stead. Mr. Clifton was, we believe, the only member of the profession on the Middlesex Bench.

Mr. Clifton's practice was extensive and arduous, including a large number of obstetric cases. His labour was increased by the great kindness of his disposition, which induced him to wait long and well on patients or families that were in trouble or sickness, even when his professional services were not of immediate use. His professional judgment was good. He was very methodical in his habits, going out and coming in with the regularity of the clock. Some of his habits were peculiar, and showed that a great deal of strength underlay the genial kindliness of his nature. Pleasure was always subordinated to work. After qualifying in 1841 he took a week's holiday. Thereafter he went for thirty-seven years without twenty-four hours' holiday. His holiday, which consisted chiefly of a few hours' fishing, was always preceded by a day's work. Within these sharply defined limits he found time to dine with a friend or take part in public affairs. He made a point, in the late hours of the night, of making up his books and his list of patients for the morrow. If he were disturbed at night, as he was very often, he never went back to his bed on returning home, but took such rest as he could get in an easily extemporised position in his study.

For a few years past the large and powerful frame of Mr. Clifton had shown signs of impairment and failure, and for a few months past it had been only too evident that his public work was done. His resignation, a few weeks ago, of the Membership of the Medical Society, of which he was one of the founders, was accepted with deep regret and pain by the members. Diabetes and albuminuria, with various and painful secondary consequences, involved a long illness, in which he was most affectionately nursed by his sisters, who have now to feel his absence. Mr. Clifton was never married. A few years ago he took into partnership Mr. Frank Godfrey, who will have to conduct the practice that for a century has been so well conducted by Mr. Clifton and his family.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College at a meeting of the Court of Examiners on the 20th inst.:—

Ashton, Charles Ernest, Guildford-street.
Bolton, Alfred, Warrington.
Breach, James Henry, L.S.A., Yattenden, Newbury.
Clark, Oscar William, Cowick, near Selby.
Collins, George William, Adelaide-road.
Cooper, Walter, L.S.A., Croydon, Surrey.
Curtayne, Herbert Maxwell, Melbourne, Victoria.
Falls, William Coultard, Buckingham-palace-road.
Inger, John William, Nottingham.
Lunn, Ernest Craven, L.S.A., Hull.
Mason, John, Kirkby Stephen.
Roe, Robert Bradley, Melbury, Dorset.
Roth, Reuter Emerick, Wimpole-street.
Stokes, Arthur Samuel, Caldecott, Leicester.
Thomas, John, L.R.C.P. Lond., Ystalyfera, South Wales.
Webster, John Arthur, Manchester.

The following gentlemen were admitted Members of the College on the 21st inst.:—

Alexander, C. A. A,, B.A. Cantab., Ardrossan, N.B.
Atkinson, Thomas Renel, Dawlish.
Beattie, Henry, Albert-square.
Boot, Arthur Edward, Harrington-square.
Briggs, Christopher Duffield, Tamworth.
Brooks, James, Blackburn.
Brunton, Charles Edward, East Dereham.
Clapp, George Tucker, Exeter.
Coxwell, Charles Fillingham, B.A. Cantab., Brighton.
Davis, Charles Daniel, Kilburn.
Fielden, William Eckett, Walthamstow.
Harris, Underwood Arthur C., Tufnell-park.
Hawksworth, Herbert Byfield, Canterbury.
Holthouse, Edwin Hermus, B.A. Cantab., Helidon, Northampton.
Jones, Thomas Wm. Carmall, Westbourne-street.

King, Thomas Mason, Windermere.
Rygate, Robert Edward, Wellington, N.S.W.
Squire, John Edward, Orchard-street.
Thomas, Stanley Temple, Churchdown.
Wöhrnitz, Ferdinand Broër Mathiew, Mauritius.

The following gentlemen were admitted Members of the College on the 24th inst.:—

Baker, James Barrington, Bassett-road.
Clatworthy, Herbert, L.S.A., Chatham.
Glassington, Charles William, Fulham-road.
Greswell, Daw Astley, Louth.
Harper, James, Windsor.
Johnson, Geo. Lindsay, M.A. Cantab., Upper Norwood.
Marsh, George Ryding, Greenhithe, Kent.
Meaden, George Anderson, Raymond-buildings.
Newcombe, Frank, L.S.A., Derby.
Nicholls, William John, Washingborough, Lincoln.
Oakeley, John Lewis Bagnall, Bournemouth.
Orchard, Alfred, Ashby-de-la-Zouche.
Revell, George Toms, Ivy Bridge, Devon.
Scott, Bernard, Brighton.
Starling, Edwin Alfred, Sutton, Surrey.
Studer, Benjamin, L.S.A., Linthal, Alsace.
Sutton, Samuel Walter, L.R.C.P. Lond., Reading.
Taylor, Frederic Ernest, Derby.
Tyrrell, Charles Robert, Hornsey-lane.
Ward, Lawrence Thomas, Mile-end-road.

The following gentlemen were admitted Members of the College on the 25th inst.:—

Brookes, Robert, Croft, near Leicester.
Gripper, Walter, M.B. & B.A. Cantab., Onslow-square.
Johnston, Walter, St. Mary's-square.
Macnutt, George Augustus, Barnet, Herts.
Palmer, John Irwin, Blackheath.
Smith, Gilbert Thomas, Richmond-crescent.
Watson, Solomon George, Tottenham.

The following gentlemen were admitted Members of the College on the 26th inst.:—

Biden, Edward James, L.S.A., Peckham.
Crossley, Charles, L.R.C.P. Edin., Leicester.
Downes, Charles Haggar, L.S.A., Sydenham.
English, Edgar, L.S.A., Whitby.
Kidd, Arthur, Liverpool.
Legge, William Heneage, L.S.A., Derby.
Lewis, William Henry Phillips, Guilsford, S. Wales.
Mahomed, Arthur G. Sulieman, L.S.A., Brighton.
Rogers, James Macdonald, L.S.A., Berners-street.
Smith, Henry, L.S.A., Plumstead, Kent.
Whistler, Charles Watts, Ashburnham.

Of the 168 candidates admitted to examination during the past fortnight, 99 passed to the satisfaction of the Court and obtained their diplomas; 10 passed in Surgery, and when qualified in Medicine will be admitted Members; the remaining 59 failed to reach the required standard, and were referred for six months' further professional study. Two candidates who had passed in Surgery at previous examinations, having subsequently obtained a medical qualification recognised by the College, were also admitted Members.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Jan. 20th:—

Blythe, Joseph Charles, Hendidley, Newtown, Mon.
Dancy, Horace Michael, Turner's-hill, Crawley.
Girdler, Geo. Toussaint, Westminster Hospital.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Arthur Edensor, Guy's Hospital; Edward Ferdinand Grün, London Hospital; Harold George Hathway and Arthur Lloyd Macleroy, St. Bartholomew's Hospital; Hugh Stott, St. Mary's Hospital.

At the Preliminary Examination in Arts held at the Hall on Jan. 21st and 22nd, 84 candidates presented themselves, of whom 45 were rejected, and the following 39 passed and received certificates of proficiency in General Education:—

FIRST CLASS (in order of merit).—1st: Cornelius Clement Caleb. 2nd: W. V. Carden and Caroline Keith. 4th: Josephine L. MacDonogh.

SECOND CLASS (in alphabetical order).—H. D. Adcock, Jas. Anderson, A. H. Armstrong, G. P. Barton, John Bate, L. Bathurst, H. G. Beville, J. Blackford, C. Campbell, A. E. Carey, C. Christopherson, Elizabeth S. Collier, Horace S. Collier, Jessie Crosfield, William Davies, A. C. Gaskin, T. Greaves, E. T. Gregory, G. C. Harrington J. J. Lewington, E. H. Lingwood, B. MacDonogh, A. J. H. Montague, Elise Morgan, E. J. Neville, F. Norman, C. C. Piper, R. J. Reece, Eliza Jane Stacey, Oswold R. Swete, E. S. Wallis, Lydia Maria Webb, W. P. West, Frank F. White, Harrie Yeo.

COLLEGE OF PHYSICIANS IN IRELAND.—At the January examinations the following obtained the licence in Medicine and Midwifery of the College:—

MEDICINE.—Humphrey John Broomfield.

MIDWIFERY.—Robert Samuels Archer, Humphrey John Broomfield, Nicholas John Halpin (Surgeon, Bengal Army).

The undermentioned Licentiates have been admitted Members:—

James Berry Kenny, Alex. Lane, George Lyndon, Hugh Warnock.

LORD WINDSOR has been elected President of the Children's Hospital, Birmingham.

DR. THOMAS W. THURSFIELD has been placed on the Commission of the Peace for the borough of Leamington.

MR. W. T. DREW, L.R.C.P. Ed., &c., of the Egham District of the Windsor Union has received the Government grant for successful vaccination (fourth time).

MR. J. A. KINGDON, F.R.C.S., has resigned his honorary surgeoncy of the City Dispensary—a post which he has held for thirty years.

EXPLOSION IN AN INFIRMARY.—The boiler in the kitchen of the Tiverton Infirmary exploded on the 22nd inst., while the domestics were at dinner. One boy was killed on the spot, and a nurse was severely injured. The cook escaped almost unhurt. The room was completely wrecked.

FORTY anti-vaccinationists were brought up at the Bradford police-court on the 17th inst. charged with neglecting to have their children vaccinated. In none of the cases was the offence denied, and the defence was "conscientious objection." The Bench, in some of the cases, only inflicted a fine of *6d.*, remitting the costs altogether, while in other cases orders were made to have the children vaccinated within three months. Most of the defendants had been previously summoned and convicted of a similar offence.

COLLEGIATE LECTURES.—The annual courses of lectures will be commenced at the Royal College of Surgeons on the 2nd prox., by Professor Parker, F.R.S., who will deliver nine lectures on the Structure of the Skeleton in the Sauropsida, to be followed by Professor Flower, F.R.S., who will give nine lectures on the Anatomy, Physiology, and Zoology of the Cetacea. Professor Butlin will continue his course on the Relations of Sarcoma to Carcinoma. Professor Treves will deliver one lecture on the Pathology of Scrofulous Affections of Lymphatic Glands. Professor Hutchinson will follow with six lectures on the Laws of Inheritance in Relation to Disease. Finally, Professor Gerald Yeo will give three lectures on the Contractile Tissues.

BOOKS ETC. RECEIVED.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office oj* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

ANDERSON, M. S., M.B., C.M., has been appointed House-Surgeon to the Paisley Infirmary.

BRADFORD, Dr. E. H., has been appointed Surgeon to Out-patients at the Boston City Hospital (U.S.A.), vice Dwight, resigned.

CHITTENDEN, C., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Agent to the Hearts of Oak, Lee and neighbourhood; the Prince Alfred; and also to the Rose of Lee and Duke of Edinburgh Sick and Benefit Societies, vice Reginald Clarke, M.R.C.S.E. Also to the Crown, the Summerfield, and the Tabernacle.

CODNER, J., B.M. & M.S., has been appointed Medical Officer to the Corfe District of the Taunton Union.

DAVIES-COLLEY, J. N. C., M.B., M.C., F.R.C.S.E., has been appointed Surgeon to Guy's Hospital, vice Cooper Forster, resigned.

DAVISON, R., M.B., M.R.C.S.E., has been appointed Medical Officer to No. 1 District Workhouse, and Public Vaccinator of the Battle Union, vice E. Smith, L.R.C.P.L., M.R.C.S.E., resigned.

DINNEN, W. T., L.K.Q.C.P.I., M.R.C.S.E., has been elected Honorary Surgeon to the Flintshire Dispensary, Holywell.

DITCHETT, W. E., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the Louth District and the Workhouse of the Louth Union, vice W. D. Ditchett, deceased.

FAGGE, C. H., M.D., F.R.C.P., has been appointed Physician to Guy's Hospital, vice Habershon, resigned.

FARMER, E. W. W., M.R.C.S.E., L.S.A.L., has been appointed Resident Medical Officer to the Seamen's Infirmary and Royal Dispensary, Ramsgate.

FINLAY, D. W., M.D., C.M., M.R.C.P.L., has been appointed Lecturer on Forensic Medicine at the Middlesex Hospital School of Medicine.

FISHER, T. W., M.D., has been appointed Superintendent of the South Boston Lunatic Asylum (U.S.A.), vice Walker, resigned.

FLACK, J., L.R.C.P., M.R.C.S.E., has been appointed Medical Officer to the City of London Lying-in Hospital, for the Bethnal-green District, vice W. Owen, resigned.

GILROY, J., L.F.P. & S., L.M., has been appointed Parochial Medical Officer and Vaccinator for the Parish of Middleborough, Dumfriesshire, vice G. R. Underwood, M.B., resigned.

HIRONS, G. M., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed an Honorary Surgeon to the Bournemouth General Dispensary.

LOVE, A. E. B., M.R.C.S.E., L.S.A.L., has been appointed an Honorary Surgeon to the Bournemouth General Dispensary.

LUDWIG, G., M.D., M.R.C.P., has been elected Honorary Assistant-Physician to the German Hospital, Dalston.

NAPIER, J., F.C.S., has been appointed Public Analyst for the Borough of Sudbury. £5 5*s*. per annum and fees.

OXLEY, Mr. H. R., has been appointed a House-Physician at the London Hospital, vice Wolfenden, resigned.

ROBERTS, R., L.R.C.P.Ed., L.F.P.S.G., has been appointed Medical Officer to the Llanfairtalhaiarn District of the St. Asaph Union.

ROUÉ, W. B., M.B., C.M., has been appointed one of the Visiting Physicians to the Bristol Hospital for Sick Children and Women.

STOKES, A. W., F.C.S., has been appointed Public Analyst for the Parish of St. Matthew, Bethnal-green, vice Tidy, resigned.

SWABY-SMITH, C., M.R.C.P.Ed., M.R.C.S.E., has been appointed by the Director-General A.M.D. Medical Officer in Charge of H.M. Troops at Seaforth Battery.

TICEHURST, A. R., M.R.C.S.E., L.S.A.L., has been reappointed Surgeon to the Children's Convalescent Home, St. Leonards-on-Sea.

TOWNLEY, A. T., L.F.P.S.G., has been appointed Medical Officer of Health for the Oswaldtwistle Urban Sanitary District, for one year, vice Booth, deceased.

WILSON, R. J., F.R.C.P.Ed., M.R.C.S.E., has been reappointed Physician to the Children's Convalescent Home, St. Leonards-on-Sea.

Births, Marriages, and Deaths.

BIRTHS.

APPLEYARD.—On the 30th October, at Berriedale Cottage, Longford, Tasmania, the wife of James Appleyard, J.P., M.R.C.S.E., & L.S.A.L., of a son.

BODY.—On the 13th inst., at Crediton, Devon, the wife of H. Marten Body, M.R.C.S.E., of a daughter.

CAMPBELL.—On the 20th inst., the wife of William Campbell, L.R.C.S.Ed., of Wellington-square, Hastings, of a son

COLLINS.—On the 22nd inst., at St. Austell, Cornwall, the wife of Walter C. Grosett Collins, M.D., of a daughter.

ELLIOT.—At Cliffe House, Ruyton Eleven Towns, Salop, the wife of Henry F. Elliott, F.R.C.S.E., of a son.

FRANCIS.—On the 22nd inst., at Bourton, Dorsetshire, the wife of George P. Francis, Surgeon, of a son.

GRABHAM.—On the 18th inst., at Madeira, the wife of Michael C. Grabham, M.D., F.R.C.P., of a daughter.

MYRTLE.—On the 19th inst., at Harrogate, the wife of A. S. Myrtle, M.D., of a son.

RICE.—On the 12th inst., at Swift's Hospital for the Insane, Dublin, the wife of William Rice, F.R.C.S., Medical Superintendent, of a son.

SANKEY.—On the 14th inst., at Sandywell-park, Gloucestershire, the wife of Arthur O. Sankey, Esq., of a son.

MARRIAGES.

BATTISS—FRANCKEISS.—On the 11th inst., at St. Mary's, Kingston, W. S. Battiss, M.R.C.S.E., to Laura F. Franckeiss.

DANIELL—KIRKMANN.—On the 19th inst., at St. Mark's, Kennington, Herbert E. Daniell, M.B., of Strood, Kent, to Edith, youngest daughter of the late W. Kirkmann, Esq.

HUTCHINSON—HOOD.—Oh the 20th inst., at Christ Church, High Harrogate, by the Very Rev. Canon Gibbon, M.A., Vicar of the Parish, S. J. Hutchinson, Esq., of Brook-street, Grosvenor-square, London, and Acton, Middlesex (son of the late Samuel Hutchinson, Esq., of Manchester), to Jeannie, youngest daughter of G. Hood, Esq., of Grosvenor Villas, Harrogate.

DEATHS.

CLIFTON.—On the 21st inst., at his residence, Cross-street, Islington, Nathaniel Henry Clifton, F.R.C.S.E., aged 63.

GREGOR.—On the 17th inst., at Institution-road, Elgin, Robert Gregor, M.D., aged 69.

HARLAND.—On the 20th inst., at Chillingworth House, Tunbridge Wells, Sarah Frances Julia, wife of Henry Harland, M.D., formerly of Mayfield and Wadhurst, aged 45.

WOOD.—On the 25th inst., at his residence, Darnaway-street, Edinburgh, suddenly, Andrew Wood, M.D., F.R.C.S.Ed.

WRIGHT.—On the 19th inst., at 128, Walworth-road, of acute laryngitis, Arabella Hutfield, the beloved wife of Morden Wright, M.R.C.S.E., L.S.A.L.

Medical Diary for the ensuing Week.

Monday, Jan. 31.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8½ P.M. Dr. Brunton, "On a Case of Gunshot Wound of the Brain of twenty-nine years' standing (the specimen will be shown)."—Mr. Edmund Owen will exhibit three Children who have recovered from Abscess in the Knee-joint after simple free drainage and rest.—Mr. Francis Mason will show (1) the specimen of Disease of the Testicle, taken from the patient brought before the Society in November last. (2) The patient shown at this Society in 1875 with Tumour of the Palate. (3) A Case of Removal of Upper Jaw five years after the operation.

Tuesday, Feb. 1.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

ROYAL INSTITUTION.—3 P.M. Professor Edward A. Schäfer, "On the Blood."

PATHOLOGICAL SOCIETY OF LONDON.—8½ P.M. The following specimens will be shown:—Case of Strangulated Hernia; Ruptured Aorta; Three Cases of Recurrent Multiple Sarcoma; Localised Scleroderma (living specimen); Congenital Truncation of Forearm; Unilateral Hypertrophy of Head; Drawings of Localised Scleroderma; Sacral Tumour containing Fœtal Structures; Case of Abscess of the Liver; Case of Chloasma.

Wednesday, Feb. 2.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL. — Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

KING'S COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at 1 P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL. — Operations, 2 P.M., and on Saturday at the same hour.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN. — Operations, 2½ P.M.

EPIDEMIOLOGICAL SOCIETY.—8 P.M. Dr. Squire, "On Instructions for Vaccine Inoculation."—Surgeon-General C. A. Gordon, "On certain Considerations regarding Cholera and Fever, more especially with reference to India and China."

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Annual Meeting; Election of Officers and Council, President's Address, and other communications.

SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND SCIENCES.—Mr. Stephen Bourne, "On Trade Prospects."

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

Thursday, Feb. 3.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL. — Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

ROYAL INSTITUTION.—3 P.M. Mr. Francis Hueffer, "On the Troubadours."

HARVEIAN SOCIETY.—8½ P.M. Dr. Hughlings Jackson, "On a Case of Temporary Hemiplegia after Localised Convulsion."—Dr. Fletcher Beach, "On Types of Imbecility."

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC. — 5 P.M. Dr. Ramskill, "On the Treatment of some Forms of Epilepsy."

Friday, Feb. 4.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—8 P.M. Dr. A. Wilson, "On Colonial Organisms."

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — 4 P.M. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

Saturday, Feb. 5.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. S. Colvin, "On the Amazons."

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

FROST, FLOODS, FOGS; SNOWS, SEWERS AND SANITATION.

OUR recent experiences in regard to the weather are happily altogether exceptional. The long-continued frost, with the complication of fogs, has exercised a most depressing effect on most persons, although the infliction is not without its collateral good influences on the few who, being in excellent health or enjoying the mental disposition distinguished by Charles Dickens in the character of Mark Tapley, are able to respond to the provocation of external cold by the acceleration of their internal heat-production. Moreover it is believed by good authorities that the early snow and frost, if not unduly prolonged, will act advantageously on the process of seed germination and vegetation generally, so that hereafter the crops may be larger and better for the repression they are now suffering. It would be well if we could hope that the cold would exercise a salutary effect on the public health by arresting the progress of contagious and infectious diseases. Unhappily, however, there is reason to fear the huddling together for warmth and crowding in-doors, certain to ensue among the poor in consequence of the intense cold, will concentrate, and thereby intensify, the virulence of "catching" diseases to an extent which must more than antagonise any beneficent action which the low temperature might otherwise exert on the morbific germs. Moreover it is always necessary to remember that if cold to some extent checks the activity of disease, it in a more than corresponding degree lowers the vitality of the organism, and thus diminishes the natural safeguards against its invasion. The floods which have occurred—to the lasting disgrace of our domestic government—have caused and will certainly yet entail much grievous suffering and manifold maladies. The snow in our streets is not simply an obstacle to traffic, but a source of danger to health. Either intentionally or in the process of an occasional thaw it will find its way into the sewers, and the sewer gas can scarcely fail to be driven back into the houses. How much better it would be to provide the country with a representative Minister of "public health" in Parliament than to allow these matters of detail to be dealt with piece-meal? The country might be saved considerable expense and the population serious disease if only the interests of "public health" were gathered into a focus and recognised at head-quarters by a Government careful of home affairs and the welfare of the people not less than of those questions which occupy statesmen more than they benefit the people at large.

MEDICAL PRACTITIONERS IN QUEBEC.

M.R.C.S. ENG., L.S.A.—There are, we believe, about a thousand licensed medical practitioners in the province of Quebec, which is in the proportion of nearly one to every hundred of its population.

Examinations at the Royal College of Surgeons.

E first meeting for the present session of the Court of Examiners of the Royal College of Surgeons for the final examination of candidates for the Diploma of Membership was held on the 14th inst., when 164 candidates presented themselves, to whom the following questions on Surgical Anatomy and the Principles and Practice of Surgery were submitted, when they were required to answer at least four (including one of the first two) out of the six questions :—

1. Describe the anatomy of the parts concerned in femoral hernia, and the steps of the operation for its relief when strangulated.
2. State the facts respecting the epiphyses of the humerus, radius, and ulna, which are important in surgical practice.
3. Describe the symptoms caused, first, by a subcutaneous rupture, and, secondly, by an open wound of a popliteal aneurism. State what treatment ought to be pursued in each case.
4. Describe the fractures of the neck of the femur and the upper third of its shaft, and point out the signs and symptoms by which they are diagnosed.
5. Under what circumstances would you recommend the removal of the eyeball? Describe the operation and the after-treatment.
6. How would you recognise uric acid in the urine? First, by the naked eye; secondly, by the microscope. State the principal conditions under which it is met with.

The following were the questions on the Principles and Practice of Medicine submitted to those candidates who had not previously btained any recognised medical licence :—

1. Whence are hydatids derived? What organs do they chiefly infest? Discuss the morbid anatomy, symptoms, and treatment of hydatids of the liver?
2. Describe the contracted granular kidney. Mention the morbid conditions under which it is especially apt to be developed; and enumerate, and, as far as you can, explain the lesions and symptoms to which it gives rise.
3. What are the indications and counter-indications for the employment of opium? State the composition and average dose of each of the following pharmacopœial preparations :—Acidum nitro-hydrochloricum dilutum, pulvis ipecacuanhæ comp., decoctum aloes comp., pil. conii comp., pil. hydrargyri subchloridi comp., and pulv. kino comp.

Sanitation in Chertsey.

ITH reference to some observations we made a fortnight ago, the *Surrey Advertiser* observes :—

"Our usually well-informed contemporary appears to be under a misapprehension in this matter. In our issue of December 25th will be found the facts as reported—the removal of the deceased (a draper's assistant) to the workhouse as a small-pox patient; the disease subsequently found to be measles, and his death on Dec. 10th, bronchitis and malignant sore-throat having set in. On Dec. 22nd the Rural Sanitary Authority held an inquiry, when none of the deceased's friends appear to have been represented, but at which a general feeling was expressed that all was right that was done. In our last issue we reported that owing to letters from the relatives of Spiers and from the Local Government Board on the matter, it was determined to ask for an inquiry to be held by the Local Government Board. This will, we trust, elicit the full facts. With reference to the closing question of THE LANCET we may remark that a 'room' in the infirmary has been set aside for small-pox patients. As to why an infectious disease hospital is not constructed apart from the workhouse, that is a question which many other places besides Chertsey would like to have answered."

M. D. must refer to the advertising columns of our Students' Number.

Student.—Dunglison's, Fowler's, or Mayne's.

r. Redwood (Rhymney).—The reports can be obtained of the medical officer of health of the district.

r. Alfred Philipps.—We cannot call to mind the paper named. Probably the subject mentioned was referred to incidentally only.

"Gratitude for Vaccination."

R. CHALMERS MORTON, of Northchurch, writes to *The Times*, as follows :—

"SIR,—Will you allow me once more to name Stephen Jenner in your columns? Ten years ago you let me tell his story (see *The Times*, July 27th, 1871), and thanks to the contributions then and since received, a monthly payment of £2 has ever since doubled his slender income, and saved his poor circumstances from becoming intolerable. Except that three liberal annual contributors of £5 continue to stand by it, that fund is for the present exhausted. I submit that it ought to be replenished. Mr. Stephen Jenner, now in his eighty-eighth year, living at Heathfield, near Berkeley, is the grandson of Dr. Edward Jenner's younger brother. He was in his childhood himself the subject of many of the test experiments by which his great uncle discovered and established the safety conferred by vaccination. In his youth he was his uncle's favourite associate. He has led a blameless life. It is not necessary that the explanation of his poverty should be given here. It can be given to anyone who asks for it. But it is a pitiable thing that one so nearly related to so great a human benefactor should be dependent in his extreme old age on a gift of 10*s*. a week to save him from destitution."

Mr. G. Smith of Coalville.

THE *House and Home* for Jan. 22nd contains a good portrait and an appreciative though brief *résumé* of the labours of Mr. George Smith of Coalville, whose exertions on behalf of the canal population we have had frequent occasion to notice. Mr. Smith's philanthropic efforts have been extended to the brickmakers and the gipsies, whose habits and surroundings, physical and moral, it has been his life work to endeavour to ameliorate and improve.

THE APPLICATION OF WARMTH TO THE HEAD.

To the Editor of THE LANCET.

SIR,—In many cases of partial or complete suspended animation, especially those connected with cold, valvular defects, and stillbirth, I would suggest the trial of the application of warmth to the head.

I am, Sir, your obedient servant,
CHARLES YOUNG, Surgeon, &c.

Chilton-Polden, Jan. 18th, 1881.

THE TERMS OF ATTENDANCE ON ODDFELLOWS.

To the Editor of THE LANCET.

SIR,—In reply to the letter of Mr. Lys in your last number, permit me to state that the Loyal Good Intent Lodge (No. 6264) pays its medical officer five shillings a year for each member residing within three miles of the lodge-house, "and in no case will sick pay be granted to those whose sickness is brought on by their own misconduct"—extract from rules.

I am, Sir, yours faithfully,
Watford, Jan. 26th, 1881. F. H. WILSON ILES.

Dr. J. H. Battye.—Silicon lozenges can, we believe, be obtained through any druggist.

Mr. W. A. Dingle.—If our correspondent will refer to Guy and Ferrier's Forensic Medicine (p. 529), he will find among *occasional* symptoms of opium poisoning "delirium, convulsions (most common in children), sometimes alternating with stupor, &c." So that Mr. Irving, in order to personate the chief part of a tragedy, must have descended to imitating *occasional symptoms, most common in children.*

G. A.—We have no recollection of the paper.

WANTED—A DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—I wish to report a case I attended some time since, which I think may be of interest to the profession, and on which I would like the opinion of some of my medical brethren as to what was the disease and what the cause of it. On August 11th I was called to see a little girl, aged four years, named A. C——. I found her sitting on her grandmother's knee, face flushed, and extremely fretful, so that it was very difficult to examine her. I found on inquiry, however, that she complained of great pain in her head, and some in her back and limbs; bowels were constipated; tongue coated of a yellowish colour; breath very offensive. I diagnosed worms and bilious fever. I prescribed santonine, calomel, and quinine in small doses. On the 14th I called to see the child again, who appeared much better—so much so that I considered it unnecessary to return unless sent for. On the 15th I inquired after the child, and was told that she was still better. On the evening of the 16th I was sent for in great haste, with the message that the child was dying. I went as soon as possible, and found it lying on its bed. Breathing easy; temperature 101°; pupils of eyes dilated and insensible to light; quite unconscious; head hot, extremities comfortable. From what I could learn it had had tetanic spasms, and since had fallen into this comatose condition. I prescribed cold to head, sinapisms to feet and legs, quarter of a grain of calomel every two hours, and a mixture of bromide and iodide of potassium.—17th: Still in same condition. Put a blister at the back of the neck, and gave a dose of castor oil and turpentine; afterwards continued treatment as before.—18th: Child completely roused up, and wanted to eat. She partook during the day plentifully of crackers and milk and a very little chicken broth. Bowels had been moved several times, and thirteen worms had been expelled by them, and one vomited. On the evening of the 18th and morning of the 19th she suffered from tetanic spasms again, relapsing into a comatose condition.—20th: Little change, but in the evening swallowing appeared difficult for the first time, and her friends gave no medicine. Another doctor was sent for, without my knowledge, on the 21st, and called the case one of cerebro-spinal fever. He found the child, who I saw shortly after, with a temperature of 103°, pupils still dilated, and the right eye drawn inwards, looking towards the nose. He prescribed a mixture containing ten drops of tincture of belladonna and five grains of bromide of potassium every two hours, also hot boiled corn to spine. On the 22nd I met and told him that I thought the cerebro-spinal symptoms which existed were due to reflex action caused from irritation set up by ascarides, and I finally got him to tell the friends that the state of matters then existing might not be spinal fever proper (as stated by him on the previous day, when I was not present), but might be, using his words, "caused by cholera infantum, fever and ague, or worms, &c." The child died the same evening. Now, what I wish to know is, was this a case of spinal fever? From the history I think not, but that worms were the exciting cause of the cerebro-spinal trouble. Apologising for encroaching on your valuable time and space, I am, Sir, yours respectfully, WATSON L. KING, M.D., &c.

Ohio, Oct. 25th, 1880.

THE CORONERS' ACT OF ONTARIO.

THIS measure, passed at the last session of the Ontario Parliament, appears to have given rise to much questioning and dissatisfaction in the Canadian mind. One feature at least in the new Act certainly seems remarkable. It is enacted (we quote from the *Canada Lancet*) that a coroner must, before issuing his warrant, make a declaration in writing and on oath before a magistrate that he believes, from information received, that the deceased did not die from natural causes, but from negligence or foul play, and that therefore an inquest is required. This is surely a cumbrous and vexatious method of putting a check on any tendency that may be exhibited to hold unnecessary inquests.

PROTECTION AGAINST UNJUST OBSTETRIC JUDGMENTS IN COUNTY COURTS.

To the Editor of THE LANCET.

SIR,—A case has just been tried in a county court in which I figured as plaintiff in respect of a midwifery engagement, a verbal agreement only, without witnesses, constituting the basis of the action, and it is in consequence of an adverse verdict that I deem it my duty to lay the particulars before you and your numerous readers, and to ask what course in respect of these engagements ought medical men to pursue in order to protect themselves against the repudiation, partial or complete, of a verbal midwifery engagement by the patient or her friends?

And now as to my own case. I was requested by an artisan earning good wages to attend his wife, and as the distance from my residence to his was more than a mile and a half, I informed him that my fee would be two guineas, which at the time he agreed to pay, but afterwards, the case being over, he paid me one guinea, repudiating his liability for the other, together with a further charge of ten shillings and sixpence for four bottles of quinine mixture which it became necessary to prescribe subsequently. Here let me remark that I paid eight visits to the patient during the following fortnight, for which no charge was made.

As to the case itself, it was one of placenta prævia in a primpara, there being, in addition, adhesion of the placenta, and, to add to its perils, she was weak from a previous illness. I was with her the whole night, and, to complete the history, both mother and child did well. I stated to the judge that the case was beset with difficulties and perils from the commencement to the end, informing him also as to the time during which I was engaged with the patient, and to strengthen my position as opposed to the statement of the husband, who made the agreement with me, and swore that I said my fee would be one guinea, and not two, I handed to the judge my visiting-list, in which I had at the time entered the engagement and fee specified—viz., two guineas.

His Honour objected to medicine being charged for at all in connexion with midwifery cases, commented upon the easy manner in which some cases come over, as a set off, I suppose, against my remarks upon the serious character of the case in connexion with which he was to deliver judgment; and, notwithstanding my explicit declaration to the effect that I stated to the husband when the engagement was made that, "Owing to the great distance, my fee would be two guineas," and the husband's reply, "that he should like his wife to have the best attendance and advice, and that he would rather I attended her than anyone else," his Honour gave a verdict for the defendant, against which I protested, without avail.

And now, Sir, I will leave the matter in your hands and in those of my professional brethren, and ask how are we to protect our interests and obtain justice if such a verdict is to be looked upon in future as a precedent.—I am, Sir, your obedient servant, LÆSUS.

Nov. 18th, 1880.

P.S.—I enclose my card, and ought, I think, to add that I lost the major portion of a day in seeking for justice, without finding it.

*** This letter speaks for itself as a caution to general practitioners.—ED. L.

D. M. R. may consult Mr. Lawson Tait's recent pamphlet on the subject. We have no doubt that a note addressed by our correspondent to that gentleman (Birmingham) would elicit the information he desires.

A Would-be Emigrant had better apply to Moore and Co., St. Mary-axe.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Inaugural Address
ON
THE CATGUT LIGATURE.

Delivered before the Clinical Society of London,
January 28th, 1881,

By JOSEPH LISTER, F.R.S.,
PRESIDENT OF THE SOCIETY.

Gentlemen,—In thanking you for the great honour which you have conferred upon me by my election to this chair, I do so with a peculiar feeling of gratitude, because I am well aware that my personal share in the proceedings of the Society has not been such as to entitle me to hope for such a distinction at your hands. I can only strive to discharge to the best of my ability the important duties which your kindness has imposed. In considering the choice of a subject for the inaugural address which is expected from your President, I have felt precluded from presenting a summary of the labours of the Society in the past, or from tendering advice as to its conduct in the future, and after consultation with some influential members of the Council, I have decided to bring before you this evening a special subject which will, I trust, be thought not unworthy of the occasion, inasmuch as, while it is still in an unsettled or transitional state, it is full of interest for every practical surgeon, and at the same time in some of its aspects well deserves the attention of the pathologist and the physician—I refer to the catgut ligature. In adopting this course I feel it needful to crave your indulgence; for the subject is a large one, and in order to do it anything like justice I shall have to trespass for a considerable time on your attention.

The catgut ligature has in some respects exceeded my original hopes. I feared that its advantages would be limited to wounds in which putrefaction was avoided, and that if septic suppuration took place in a wound in which it was employed for securing the vessels, the ligatures would sooner or later come away like little sloughs. Such, however, has not proved to be the case. Whatever be the progress of the wound, we never see anything of the catgut, so that even surgeons who have not adopted strict antiseptic treatment have been led to employ the new material in ordinary wounds. Under other circumstances, however, the catgut has often led to disappointment. We hear of cases in which the Cæsarean section has been performed, and all has gone on well until the knots of the catgut with which the uterine wound was secured have given way, and the patient's death has been the result. Again, in ligature of large arterial trunks in their continuity several surgeons have met with bitter disappointment, the case ending in disaster from secondary hæmorrhage, or the treatment proving abortive through the channel of the vessel becoming opened up again at the site of ligature. Hence many surgeons have been induced to return to silk, even though using strict antiseptic treatment; rendering the silk aseptic by steeping it in a suitable lotion, and cutting the ends short. This practice has, however, by no means proved uniformly successful. As an instance of unsatisfactory result I may mention a case recorded by Mr. Clutton in the last volume of our Transactions. He tied the external iliac artery under strict antiseptic precautions, and the wound healed within a week; but, as I learned from a letter which he was good enough to send me at the time, "six weeks after the operation a little blister formed, and fluid began to escape, forming a small scab, and in three months the loop which had been placed around the artery came away." Such a result was not at all surprising to me, seeing that what induced me to try the animal ligature was the discovery of a small abscess about the remains of a partially absorbed silk thread, which I had applied in the same manner as Mr. Clutton, and, as it happened, to the same artery.[1] It can hardly be doubted that suppuration proceeding from the immediate seat of the ligature must be a source of danger. As an illustration of the mischief which a ligature of ordinary material may do, I may mention a case of goitre in a young woman on whom I operated on Jan. 28th of last year. It was of moderate dimensions, but the effect on the respiration was so considerable, that I determined to remove it, following Dr. Patrick Heron Watson's plan of preliminary deligation of the thyroid vessels circumferentially to the tumour. If this is effectually done, the operation is bloodless—so that as the laryngoscope applied by Dr. Felix Sémon, who had recommended the case to my care, showed that the anterior wall of the trachea was pressed back considerably by the growth, I adopted a measure which I believe would in all cases of the removal of the thyroid prove advantageous—namely, I divided the tumour in the first instance in the middle line, so as in the event of adhesion to the trachea to be able to remove the two halves of the growth at leisure, dissecting it off from the trachea more or less completely as might be desired, leaving some portions at the adherent parts, so as to avoid the deadly risk of perforation of the air-passage. But in order that the circumferential ligature of the thyroid vessels may be secure, it is essential that the material should be very strong, so that the tissues round about the tumour, including the vessels, may be thoroughly tightened up. I possessed no catgut which I felt was strong enough to bear the full strength of my hands, and therefore I was compelled to use a hempen ligature, after, of course, carefully rendering it aseptic by means of the carbolic lotion. Six of these hempen ligatures were used, three on each side. During the first eight days everything went on in a typical fashion according to the antiseptic method. There was a merely serous effusion rapidly diminishing, and we looked to the wound being healed in a few days more. But on the ninth day there was seen to be a little something of purulence mingled with the discharge; and the pus afterwards became thicker, though always in small quantity; a little could be pressed out from each side, and in a month one of the hempen ligatures made its escape. Five days later four others of the hempen threads came away, altogether unaltered, as they may be seen on one of the cards on the table where I have exhibited them. I submitted them to careful examination. They had a sour odour, and, applied to litmus paper, gave an acid reaction—that is to say, the natural alkaline condition of the blood serum had been changed to acidity by some peculiar species of fermentation. On examining them with the microscope I found the interstices of the threads of the hemp loaded with a little organism, to which I believe I happened to be the first to direct attention as to its mode of growth,[2] and to which I gave the name of Granuligera, occurring in groups of two, three, four, and so forth, as distinguished from the chains of ordinary bacteria, and of which one form at least has been since shown by Mr. Cheyne to occur very frequently in cases treated antiseptically without any interference with aseptic progress. I found that the interstices of the threads of the hemp were loaded with these little micrococci. It so happens I have had the opportunity within the last few days of obtaining a sample of these micrococci, thanks to Mr. Cheyne's kindness. He brought this flask of a pure and perfectly transparent infusion of meat to a case which I had operated on a fortnight before by excision of the ankle. The skin had been unbroken, so that I was able to operate antiseptically, and the case pursued a perfectly typical course. The wounds, which were left gaping at the time of the operation, were filled with blood-clot, which remained unaltered in appearance, though undoubtedly organised by that time, more or less. A little piece of the blood-clot from one of these wounds was introduced with careful antiseptic precautions into the flask of clear fluid, and you see it is now turbid; and there is under the microscope on the table a specimen of the little organism to which the turbidity is due. But though, under ordinary circumstances, these micrococci may be present, as Mr. Cheyne has abundantly shown, and as the excision of the ankle I have just referred to illustrates, without causing any evil, yet there may be circumstances in which they may prove mischievous, and the case of goitre which I have been relating appears to have been one of these. The micrococci developing for a protracted period in the interstices of the hempen ligature produced an acid fermentation of the serum in its most aggravated form. The acid serum became a cause of irritation, and thus the ligatures, which otherwise, being unirritating in their own substance, might have become encapsuled, and in due time absorbed, became causes of suppuration. One of the six ligatures still remained unaccounted for. In due time we sent the patient home with a small sinus remaining, a little pus always discharging from it, but it was not until the middle of September that the last ligature came away altogether unaltered. Now, gentlemen, there is no doubt whatever that if I had had catgut which I could have trusted for the operation, the catgut ligatures would have been disposed of within two or three weeks, and the healing, instead of requiring eight months, would probably have been completed in a fortnight. Here, then, we have an illustration of the great disadvantage which may arise even under antiseptic treatment from the use of the ordinary forms of ligature.

---

[1] See Observations on Ligature of Arteries on the Antiseptic System, The Lancet, April 3rd, 1869.

[2] See Transactions of the Royal Society of Edinburgh, vol. xxvii., 1875.

Animal ligatures of another kind have been provided by Mr. Barwell in order to remove these difficulties—namely, strips of the mingled yellow elastic and unstriped muscular tissues which constitute the arterial wall, obtained by spirally cutting the aorta of one of the larger animals. But though fully admitting the efficiency of these ligatures in his hands, I am given to understand that their form and size render them by no means very convenient, and, independently of this, I cannot but feel that it is unsatisfactory, if it can be avoided, to have a special material for this particular object, and that it would be better if possible to have the catgut in a thoroughly reliable condition. Catgut, of which I have samples here, is to be had all over the world in abundance. It is beautifully strong and smooth; it is prepared of various sizes, admirably adapted for all the purposes of the surgeon, and is extremely cheap. Wholesale it is sold at 12*s*. per gross, that is to say, 1*d*. per hank. But as it comes from the maker it is entirely unfit for the purposes of the surgeon. However beautiful it is in the dry state, it becomes soft and pulpy soon after it has been placed in blood serum. In one of these glasses is a piece of unprepared catgut which was placed in warm serum this morning, from the blood of a cow, and within half an hour it was in the condition in which it is at the present time, swollen, soft, and pulpy. A knot tied upon it would hold as little or scarcely better than would one on a piece of the intestine from which the catgut is derived: an utterly unsatisfactory material, soft and slippery, the knot not holding in the least. It is essential in order to fit the catgut for the purposes of the surgeon that it be altered in its physical constitution so as to be no longer liable to this softening effect by the serum of the blood. It is a remarkable circumstance that the blood serum softens catgut more than even water does. It might have been expected *à priori* that a solution of a colloidal substance like albumen would have been much less disposed than water to permeate and soften an animal tissue like catgut; but it is otherwise, and therefore we cannot test the trustworthiness of catgut by steeping it in warm water, as I formerly used to do. In order to be sure that a given specimen of catgut will answer the purpose in so far as the knot is concerned, that it shall not slip, it is needful that we steep the catgut in blood serum, a somewhat troublesome process, as it involves sending to a slaughter-house for blood.

The method of preparing catgut which I published long ago answers the purpose very well even for the ligature of arteries in their continuity, provided certain conditions in its preparation be complied with. Such at least is my own experience. This, indeed, has not been very extensive, but it has been sufficient to deserve consideration. I have tied altogether nine large arteries in their continuity with prepared catgut. Of these one was a case of ligature of the carotid in a young woman aged twenty-two, with a pulsating tumour below the angle of the jaw, in the situation of a carotid aneurism and with all the symptoms of that disease. The application of the ligature reduced somewhat the pulsation and the dimensions of the swelling, but the further cure which we hoped for did not take place. She left the hospital with a pulsating tumour, and I heard only yesterday from the medical man under whose care she is in Scotland that this tumour, for which I tied the carotid artery in 1874, still exists as a pulsating swelling, if anything rather on the increase. But though as regards the cure of the disease the ligature was unsatisfactory, nothing could be more beautiful in its effect as respects the healing of the wound without suppuration, and permanent obstruction of the artery at the seat of ligature.

A case of traumatic arterio-venous aneurism of the temporal artery may be mentioned in the category, partly because the greatly dilated condition which the naturally small artery had assumed brought it up towards the dimensions of a large trunk, and partly because the concurrent ligature of the largely dilated veins would, without antiseptic means, have been justly regarded as of considerable danger. The others were all cases of ligature of the femoral. Six were popliteal aneurisms, four of which presented nothing deserving of special remark. One was a diffuse aneurism extending up to the junction of the lower and middle thirds of the thigh. One was an enormous diffuse aneurism reaching up nearly to Poupart's ligament. It was necessary for me to tie the femoral artery about the situation of the ordinary origin of the profunda, and even there my incision opened into the aneurismal clots. The last was a case of a large arterio-venous aneurism of the upper part of the femoral, of idiopathic origin. This case was of such special interest that I hope on a future occasion to make it the subject of a paper before this Society. In all these cases except two catgut prepared by the old method was employed, and in all these nine cases the result was satisfactory, and recovery perfect, except as regards the poor young woman who has still the pulsating tumour in her neck.

As regards the mode of applying the ligature, I have always used a single reef knot, with short-cut ends, tying it sufficiently tightly to cause the giving way of the internal and middle coats. This latter point is not, indeed, essential; as I long ago surmised, and as Mr. Barwell's experience has demonstrated. But if, as in the case of catgut, the form of the ligature admits of it, the injury done to the deeper tunics is, I believe, advantageous, by leading to a salutary corroborative process of repair.

Why, it may naturally be asked, has my own experience been more satisfactory with the catgut ligature than that of many other surgeons? There are, I believe, two reasons for this: one is, that I have never ventured to tie an artery of considerable size in its continuity without having taken pains to ascertain that the catgut was of thoroughly trustworthy material; and the other reason is, that I have adopted strict antiseptic means of treatment, not only during the earlier stages of the case, but to the last. So long as any part of the wound remains unhealed, antiseptic treatment of the strictest kind ought, I believe, to be employed. Even though the sore may seem to be superficial, there may still exist a sinus leading down to the site of the ligature, and if ordinary treatment, as distinguished from antiseptic, be employed, down this sinus the septic process may advance and invade the ligature, and, inducing unhealthy suppuration and ulceration, may lead at last to disaster from hæmorrhage. I know that this has actually taken place.

But although the catgut prepared after the old method answers very well if it be of proper quality, there is this great objection to this method that it requires a long time in order to produce the requisite quality. At least two months are needed to make the ligature at all trustworthy. It is better at the end of six months, and still better at the end of a year. I possess catgut prepared in this way twelve years old. I have brought here a sample of such catgut which has been steeping in warm blood serum since this morning, and it will be seen that it remains translucent and is comparatively firm, instead of being opaque and soft like the unprepared catgut in the same serum.

Now, the length of time that the present method requires is a very serious objection. It makes the surgeon who has not prepared the catgut for himself, and kept it for a long time, at the mercy of the person who supplies it; and the person who supplies it not being aware of the enormous importance of the question of time, if he happens to have run out of that which has been long prepared, will sell what has been only a short time in the preparing liquid, and is in consequence altogether untrustworthy. A case illustrating this point occurred last year in my practice at King's College Hospital. A patient was admitted who had met with a severe wound on the ulnar side of the forearm, at the anterior aspect. The ulnar artery had been divided. This had been secured by my house-surgeon. He had also tied with catgut the corresponding ends of the various tendons that had been severed. But when I saw the patient next day I found that he could not feel with his little finger and the adjacent side of the ring finger, and therefore it was evident that his ulnar nerve also had been divided, and my house-surgeon had not thought of attending to the ulnar nerve. I therefore cut the stitches in the skin and proceeded to explore the deeper parts of the wound, in order to find the ends of the divided nerve, and tie them also together with catgut, and I found that all the catgut sutures with which the ends of the several tendons had been tied together were lying absolutely loose. The knots had slipped within the twenty-four hours, and yet this catgut had been supplied by one of our ordinary instrument-makers. He had sent us what had not been sufficiently long prepared. I took care to use proper catgut for the ulnar nerve; and the patient left the hospital with restored sensation in the fingers.

The length of time that it requires is, therefore, an exceedingly serious objection to the present method of preparation; and one great object which I have had in view to a series of experiments on this subject with a view to improving the preparation of the catgut ligature has been to devise a means, if possible, of preparation within a short time. These experiments—it may seem almost ludicrous to say so—have occupied two years of my leisure time in the past, some time ago, and after being interrupted by an accidental circumstance, have been continued in a more desultory manner since; but at length I have felt myself justified in bringing before you a new mode of preparation by which the catgut can be prepared in a short period, and at the same time in a perfectly trustworthy condition.

But before I allude to these experiments, which I must endeavour to do in a short compass—I should weary you if I were to bring a large proportion of my facts before you, though I may say out of the hundreds of experiments I have performed on the subject I have never performed one which has not added something to my knowledge of it—before referring to these experiments I wish to say a few words as to what catgut is. Catgut, as you are doubtless all aware, is prepared from the small intestine of the sheep. The gut is treated in what seems an exceedingly rude manner for so delicate a structure. It is scraped with some blunt instrument, such as the back of a knife, over a board; and by this means, as the people express it, the dirt is scraped out. That which these people call the dirt is the exquisite and complicated structure of the intestinal mucous membrane. But while the mucous membrane is scraped out from within there is also scraped off from without the circular coat of muscular fibres. The result comes to be that the intestine is converted into a comparatively unsubstantial material, consisting of two parts or bands, one more slender than the other. When the mesentery is stripped off by the butcher, the peritoneal covering of the gut shrinks into a narrow strip; and this, with some longitudinal fibres, constitutes the more slender of the two parts to which the intestine is reduced by this process of scraping. The other part is the essential material from which the catgut is prepared, and this is neither more nor less than the submucous cellular coat of the intestine. When I first visited a catgut manufactory I was astonished to find that after this scraping process the intestine could be blown up still as a continuous tube, as you see can be done with this specimen, which has been treated in the manner I have described. This exquisitely delicate structure is a beautiful anatomical preparation of the submucous cellular tissue, though made in so rude a fashion. This coat of the intestine which, in the sheep, has this extraordinary toughness, is the material out of which the catgut is prepared. For what the manufacturer calls the "ones"—the thicker form of ordinary catgut—all that is done is to twist the entire tube by means of a wheel like a rope in a rope-walk, up to a considerable degree of tightness, and then allow it to dry. It is afterwards exposed to the fumes of burning sulphur, and for some more special purposes it is bleached by the action of potash. But the essential thing is the twisting and drying; it can be prepared without the use of sulphur, as well as without the use of potash. Some specimens which I have here are prepared by water only, without the use of any other ingredient. This exceedingly beautiful structure, as I think we must consider it, as fine as a horsehair, is prepared without any reagent whatever; nothing but the animal tissue twisted and dried. For the finer kinds the tube of the submucous coat is split up by means of razor blades more or less numerous, according to the degree of splitting required, connected with a conical piece of wood, which is pushed along the tube.

Such, then, is the material with which we have to deal. The first of the more recent experiments which I performed with reference to it was made with the view of ascertaining, if possible, what part the water played in the ingredients used for the preparation by our old method. If I steep unprepared catgut in a mixture of dry carbolic acid and oil, however long it be so steeped, although it will be, of course, abundantly aseptic, it remains utterly unfit for the purposes of the surgeon; a knot upon it would still slip in a wound. But if, instead of using carbolic acid in the crystallised state, we use carbolic acid which has been liquefied by the addition of a little water, we get in course of time a properly prepared catgut. I wished to ascertain how much water was required. The carbolic acid would enable oil to dissolve a certain amount of water; would that amount of water be sufficient which carbolic acid enables oil to dissolve? Accordingly I prepared jars of carbolic oil, some containing the full amount of water we had used hitherto, some a smaller quantity, and some none at all, and placed in them portions of the same hank of catgut. In due time I proceeded to examine the result, by taking portions of gut and putting them into warm water, and leaving them for a certain time in order to ascertain how the knots would hold. To my great surprise I found that which had been steeping in the carbolic acid and oil without any water was just as good as that which was in the carbolic acid and oil with the water. This was contrary to distinct previous experience. Reflecting on the matter, I saw that the only possible explanation was that the catgut was already, so to speak, prepared before I put it into the liquid. Now it so happened that the catgut I had used was several years old; and it turned out that mere age of the catgut prepares it: that in proportion to its age it is rendered less liable to be softened by water or by blood serum, and a knot tied upon it will hold better. And thus I had, for the first time I believe, scientific evidence of the truth of what is popularly spoken of as the "seasoning" of various articles made of animal products. I asked a person who sold violin strings if there was any result from keeping the strings a long time. He said, No; the only result he knew was that they would probably get rotten. But it so happened just about that time there came an old fiddler to amuse the patients at the Royal Infirmary of Edinburgh at Christmas-time. The weather was wet, and he said that his fiddle would not work properly because the fiddle-strings were not properly seasoned. So that he was aware that fiddle-strings, which, of course, are catgut, are liable to seasoning, and require it. This was to me a very important fact, because it served to explain the success that I had had in my earlier experience with the catgut before I knew at all the proper mode of preparing it. I look back with horror at some of my early procedures with catgut. I have operated, for example, on an irreducible ventral hernia, opened the sac, divided the adhesions, returned the protruding intestines, stitched up the mouth of the sac with the catgut, and then applied stitches at considerable intervals in the skin. All went perfectly well; but the mode of preparation that I then used, if I had worked with catgut recently made, must have ended in utter disaster; the knots must have slipped in a few hours, and the intestines must have been protruded through the wound.

I need hardly say that this mode of preparation, interesting though it is, would not be satisfactory; it would only have, in a more aggravated form, the inconvenience of the extremely long period which our old method requires; and, besides that, it by no means provides all the conditions that must be fulfilled in order to provide a perfectly satisfactory state of the catgut for surgical purposes. These conditions I will now mention. In the first place I have spoken of a short period of preparation. This is very desirable. Then it is essential that the catgut should have proper strength, so as to bear any reasonable strain that the human hands can put upon it in the thicker forms; as when used, for instance, in such cases as the circumferential ligature of the thyroid vessels, in the removal of a goitre, or for securing the pedicle in ovariotomy. And it is not sufficient that it should be strong to start with; it is easy to get catgut strong in the dry state; it is necessary that it should be strong after steeping in blood serum for a while. Take, for example, the case of tumour of the thyroid. I passed in that case six ligatures; and in a former case where the tumour was larger I thought it prudent to pass as many as eight, so as to subdivide more the mass that had to be tied; but it is not convenient to tie each of these ligatures as soon as it is passed; and the process of passing takes a considerable time. Now it would be a very sad thing if the residence of the catgut among the tissues soaked with serum for a few minutes, or even a quarter of an hour, should render the catgut so soft that it should give way when we put the strain of the hands upon it. That, then, is another point that is essential, if the material is to be useful for all the purposes for which it is desired. Then, again, it is necessary that a knot tied upon it should hold with absolute security, not merely in the first instance, but after soaking for an unlimited time in blood serum. It is further needful that it should not be too rigid; for, as we shall see immediately, it is possible for catgut to be over-prepared, in which case it may remain almost like a piece of wire among the tissues, and ultimately, perhaps, come away by suppuration in consequence of the mechanical irritation which it produces. But while the animal juices must be able to soften it sufficiently to render it mechanically unirritating, yet, on the other hand, it will not do for it to be too rapidly disposed of by absorption. If it is to do duty for the ligature of an artery in its continuity in the immediate vicinity of some large branch, it must remain for a considerable time of good strength, unabsorbed, and when it is at length absorbed it is desirable that it should be removed in such a manner that while it is reduced in thickness it should still, as long as any of it remains, retain its tenacity.

Now these are a series of conditions which I assure you it is not easy to fulfil completely. I have in various experiments complied with some of them easily enough, but failed in others. Sometimes I have succeeded with all but one, and one has baffled me. I have used various materials in experiments, as you will naturally suppose. One substance that suggested itself was tannic acid, so as to convert the fibrous tissue of the catgut into leather. I succeeded well enough in some respects with tannic acid applied in different ways, but in one respect I did not succeed. I have not obtained by means of tannic acid a kind of catgut that is not too speedily absorbed. Even a piece of kid leather, cut into a suitable shape for sutures, and rendered aseptic, became too rapidly absorbed. Chromic acid was another agent which I very naturally tried on account of its well known effect in hardening tissues. Chromic acid alone does not work very well, but I found that the addition of some other substance to it aided its action very greatly. By adding, for instance, to the watery solution a little glycerine, which produces a reducing action on the chromic acid, we get a different sort of liquid, which acts much more energetically on the catgut. I was highly delighted with the results of the action of this mixture of chromic acid and glycerine; and just about this time it happened that Mr. Oliver Pemberton of Birmingham applied to me for a piece of catgut for the purpose of ligaturing the external iliac artery in a remarkable case of three aneurisms in one limb—two in the femoral, and one in the popliteal. I thought I could not do better than send him a piece of my recently prepared chromic catgut. I did so; and a month afterwards he wrote to me saying that nothing could be more satisfactory than the result. He had operated antiseptically; the wound had united by first intention, and so far as the case could go well, all had gone well. There was, indeed, gangrene of the lower part of the leg, which Mr. Pemberton had predicted would occur in consequence of the existence of four successive obstructions in the course of the arterial channel—viz., the ligature and three solid aneurisms; but the case, under proper management, was doing well. Four weeks later, however, Mr. Pemberton wrote to me again, telling me that soon after his last report the patient had begun to show signs of suppuration about the seat of the wound. After a while the abscess opened in the cicatrix, and one day the ligature which he had placed on the artery was found lying unaltered on the granulations.[3] It is now on one of the cards before you—an over-prepared ligature, which had come away, rigid and wirelike, making its way out, as a piece of glass might have done by mechanical irritation. This opened my eyes for the first time to the possibility of having catgut over-prepared. This over-preparation by means of chromic acid is, I understand, to be found illustrated in a large German school at the present time. I have been told by an American physician, who has lately been in London after spending some time at that school, that the catgut ligatures come away from all wounds to which they are applied in that clinique. They count the ligatures as they put them on, and invariably see them all before the case is done with. The catgut has been over-prepared.

It is by means of chromic acid, however, that I have at length arrived at a result which appears to satisfy all our conditions. But before speaking of the new method I wish to say a few words more with regard to the old. To what is it that it owes its virtue? In this bottle is some catgut which has been nearly ten months in our old preparing liquid—namely, one part of carbolic acid which has been liquefied by means of water to five parts of olive oil. In this other vessel, again, we have catgut which has been the same length of time in a solution of carbolic acid in water. Water will only take up one-twentieth part of its weight of carbolic acid; but the effect produced upon the catgut by the watery solution is very much greater than that brought about by the four times stronger oily solution. In the former case, as you can see, the catgut is almost black—a sort of purple black—while the other is comparatively pale, very little altered from its original colour. This circumstance shows two things. In the first place, the effect of the watery solution of carbolic acid upon the catgut explains the efficacy of the water in our old method. It is the watery solution of carbolic acid in the liquid of the old method that is the effective agent. But while that is the case, when the watery solution is mixed with oil, the fact that it is so mixed limits and checks its operation. If catgut is kept in the watery solution only, there seems to be no limit to the degree of continuous preparation of the gut, so that it becomes more and more dark in colour, and more and more difficult of absorption by the tissues. It is otherwise when the watery solution is blended with the oil. Though the process does go on for many months, there comes a time when it comes to a standstill. You need not fear that catgut prepared by the old plan is ever over-prepared. There is a specimen on the table which at the end of twelve years is as limp, after steeping in blood serum, as it would have been at the end of a single year. Therefore, we possess in the carbolic oil a means of checking any mode of preparation that we may adopt, keeping it from that time forward not materially further prepared, while at the same time the large proportion of the carbolic acid to the oil (one to five) ensures the catgut being maintained perfectly aseptic.

The method of preparation which I have now the honour to bring before you is the following: I dissolve one part of chromic acid in 4000 parts of distilled water, and add to the solution 200 parts of pure carbolic acid, or absolute phenol. In other words, I use a one-to-twenty watery solution of carbolic acid, only that the carbolic acid is dissolved not in pure water, but in an exceedingly dilute solution of chromic acid. But minute as is the quantity of the chromic acid, it exerts, when in conjunction with carbolic acid, a most powerful effect upon the gut. The first effect of the addition of the carbolic acid to the chromic solution is to change its pale yellow colour to a rich golden tint. But if the liquid is allowed to stand without the introduction of the catgut, it changes in the course of a few hours to a dingy reddish-brown, in consequence of some mutual reaction of the two acids, and a considerable amount of grey precipitate is formed. If, however, catgut about equal in weight to the carbolic acid is added as soon as the ingredients are mixed, the liquid retains its brightness, and the only change observed is a gradual diminution of the depth of the yellow colour; the precipitate, which I presume still occurs, taking place into the substance of the catgut. As soon, therefore, as the preparing liquid has been made, catgut equal in weight to the phenol is introduced into it. If you have too large a proportion of catgut, it will not be sufficiently prepared; if you have too small a quantity, it may run the risk of being over-prepared. At the end of forty-eight hours catgut steeped in such a solution is sufficiently prepared. It is then taken out of the solution, and dried, and when dry is placed in one-to-five carbolic oil; it is then fit for use. I have here a sample of catgut prepared by this method. Although it has been steeped in warm blood serum since this morning at 11 o'clock, it is still translucent and firm, without being rigid, and a reef knot tied upon it holds with the most perfect security.

The strength of the catgut depends upon different circumstances. In the first place, sheep differ as to the strength of their intestines, and the catgut-maker, if he understands his business, will insist upon having his raw material of the proper kind. In the next place, the intestines must not be allowed to putrefy; they must be taken fresh. For these things you must, of course, rely upon the maker of the catgut. In the next place, the liquid causes a certain amount of softening of the catgut, and if it is introduced in loose hanks, this will tend to produce a little uncoiling of the twisted cord, and a still greater degree of uncoiling will take place during drying. It is of very great importance that this should not occur, because it involves weakening of the thread, and that in different degrees in different parts, and this may lead to the gut giving way when you subject it to a strain. The catgut, then, should be prepared on the stretch, both when it is put to soak and when it is put to dry.

---

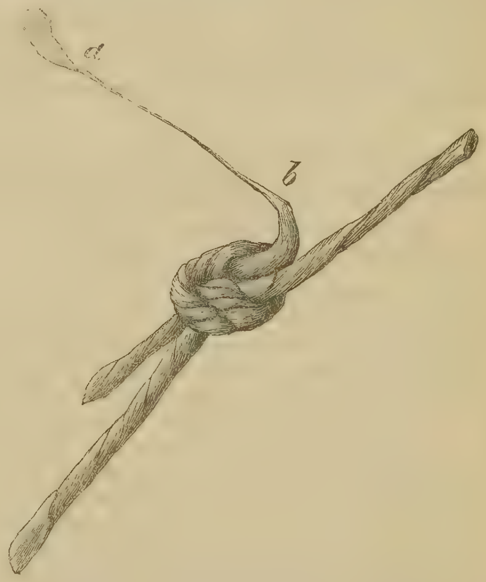
[3] For an account of this case by Mr. Pemberton see THE LANCET, August 4th, 1877.

I need not enter into the mode in which this can be done by the manufacturer. I may only say this, that the surgeon who wishes to prepare it himself may do it in different ways. For instance, he may take two large test-tubes, one a little larger than the other, and he may wind the catgut on the smaller tube, fixing one end by sealing-wax, winding it round, and then bringing it up again, and fixing the other end with sealing-wax at a higher level than the liquid will come to, putting sufficient liquid into the larger test-tube, and introducing the smaller test-tube with the catgut wound round it, with a little shot to keep it down in the liquid. After forty-eight hours he takes out the smaller test-tube and leaves it till the catgut is completely dry. I merely mention this as an illustration, and also as furnishing a hint to some surgeons in private practice who may desire to prepare the catgut themselves. Or a couple of gallipots, one larger than the other, will do just as well. But, as I have already said, the principal uncoiling takes place during drying, and for all ordinary purposes a sufficiently good article is got by putting the catgut loose into the liquid, and putting it to dry on the stretch, by tying the ends of each hank to two fixed points in a room.

In the dry state, catgut prepared by this method is as strong as need be. As to strength in the condition after steeping in blood serum, I confess it is only this very day that I have obtained evidence that catgut thus prepared is really all that we can desire in that respect. The catgut of the hank from which this specimen was taken measured in the dry state 2⅔ hundredths of an inch in diameter, and broke at 13 lb. 6 oz. I have found by experiment that 10 lb. is the utmost strain that my arms are able to put upon a cord. 13 lb. 6 oz., then, is amply sufficient; while, at the same time, the catgut is not at all too large for going into the eye of an aneurism needle. Having obtained the other day some fresh blood of a cow from the slaughter-house, I took some of the serum to-day and put two pieces of this same hank of catgut in the serum, and I placed it in a stoppered bottle in a warm box, at a temperature of 98° F. After more than half an hour I tested the breaking strain (I must not stop to explain how that is done), and I found that the breaking strain of the same catgut, which in the dry state had broken at 13 lb. 6 oz., was 11 lb. 4 oz.; that is, though suppled by the serum, it had only lost in strength 2 lb. out of 13 lb. I think that is really all that can be desired.

The only remaining condition to be considered regarding the new catgut is its suitable behaviour among the tissues. Before describing this I wish to say a few words regarding the manner in which catgut is absorbed. It has been said of late by various persons that the catgut is dissolved by the serum. I must confess that this is entirely contrary to my own experience. I have already said that in order to test the quality of catgut you must have it steeped in blood serum. I have tested in this manner catgut prepared in various ways. The serum has sometimes been putrid; sometimes it had no smell at all, and sometimes it had a little odour. The serum has been kept about the temperature of the body, but I have never seen the slightest indication of any chemical solution of the catgut. Then, again, as to the behaviour of the catgut in the body. Suppose we use it as a stitch, if the catgut were disposed of as a matter of chemical solution, we should expect that when it is employed as a suture, and a piece of our protective is put over it, which is always kept moist with serum perpetually oozing from the wound, the outer parts of the stitch, the parts outside the skin, as well as the parts among the tissues, would show signs of diminution. It is never so. The diminution is always absolutely limited to the parts within the tissues. It is still more striking, as was suggested to me by Mr. Cheyne, to consider the case of catgut used as a drain. There its very function is to drain out the serum, and it is perpetually washed with it. You might suppose that a stitch might perhaps get a little dry. Here there can be no mistake, the serum from the wound is perpetually flowing over the gut, yet, as in the other case, we find the diminution of the catgut is absolutely limited to the part within the tissues. This seems to me sufficient evidence that it is not a question of the mere chemical solution of the catgut, but of the disposal of the catgut in some way or other by the living textures.

Now, if we examine catgut in the process of diminution we find that it may be affected in one of two ways. If it has not been properly prepared, the substance of the catgut becomes converted in the course of a very few days into a soft, pultaceous mass, which, when we examine it by a microscope, we see consists of the remains of the old cellular tissue of the submucous coat, with the interstices among these fibres filled with cells of new formation. The catgut tissue is infiltrated with young growing cells, and it is obvious it is this infiltration which is the cause of the softening. But, on the other hand, if the catgut is properly prepared, instead of being infiltrated by the cells of new formation, it is only superficially eroded. I have here a pretty example of catgut prepared by the new method which has been served in that way by the tissues. You will see that at the part which was among the tissues there remains a very slender residue of the catgut, all the rest having gone; but that slender residue continued firm and translucent, still retaining its firmness, showing not even a superficial infiltration—in short, having exactly the characters that we desire for catgut required for the ligature of an artery in its continuity—viz., that till the last, even though reduced in dimensions, it shall retain its firmness and its tenacity. We know that antiseptic treatment has shown that a piece of dead bone may be absorbed provided it be not putrid; the granulations that overlap it superficially may, so to speak, erode it. It is not necessary for us now to consider how that is effected, but certainly in some way or other the granulations do what mere steeping in serum, whether putrid or non-putrid, never would do. Never, I believe, would the bone be dissolved by the serum. And just as a non-putrid sequestrum is served by the tissues, so is a well-prepared specimen of catgut—it is superficially eroded. I have here a stitch that I removed to-day from a wound made ten days ago—a wound made for stretching the anterior crural nerve, which was stretched as well as the sciatic in an aggravated case of sciatica—and you may see that as yet it shows no signs of erosion. We know by experience that if it were left three or four more days we should find it probably eroded, as the former specimen shows; but until nearly a fortnight has elapsed erosion does not begin. It proceeds gradually, and the thicker the catgut the slower does it proceed. We may fairly consider that from a fortnight to three weeks is long enough for the persistence of a ligature upon an artery in its continuity. [Three days later I removed two remaining stitches in the case last referred to, and found both of them slightly eroded superficially.]



In this woodcut the suture referred to is represented magnified five diameters. Its actual thickness was 1-50th of an inch. The part between *a* and *b* is that which had been among the tissues.

I have brought with me the carotid artery of the calf in which I first established the fact of the substitution of new living tissue for the dead old tissue of the catgut. If any gentleman will examine the specimen after the meeting he will see the ligatures of new formation incorporated with the external cellular coat of the artery. I have been strangely misunderstood as having intended to convey the idea that the catgut when it becomes organised, comes to life again. Gentlemen, such an absurd notion certainly never entered into my head, any more than, when I have spoken of the organisation of a blood-clot, I have meant by that expression to convey the idea that the blood-clot becomes organised by its own inherent virtue. I found the term "organisation" ready to my hand; it was no term of my invention. It was used with reference to lymph. Now, pathologists in speaking of lymph as becoming organised, did not, I suspect, mean by the expression to imply that it was the lymph substance that had the power of self-organisation as distinguished from any influence that surrounding tissues might exert upon it. So in the same way the expression "vascularisation of lymph," was used when it was universally believed by pathologists that the bloodvessels were formed only by loops from pre-existing bloodvessels. Nowadays, a different view may be taken, but the term "vascularisation of lymph" was employed without any notion that the lymph itself created the bloodvessels. And so when I spoke of the organisation of the blood-clot, or of catgut, I never meant to convey the idea that either the one or the other did the work itself. As to the blood-clot, we know that if it remains free from putrefaction among the tissues, it speedily becomes infiltrated with cells of new formation. Whether the white corpuscles originally present in the clot take any part in the formation of these new cells is a question now under discussion, and one, I conceive, not at all prejudiced by the use of the term "organisation of the blood-clot." With regard to catgut, I think if gentlemen would refer to my original paper in The Lancet they would see that I stated very explicitly that new tissue forms at the expense of the old, that the old tissue is absorbed by the new, and that, as the old is absorbed, new is put down in its place.

In conclusion, gentlemen, I venture to recommend the new chromic gut as in all respects deserving of your confidence; and at the same time to thank you sincerely for the patient attention with which you have listened to this long address.

ON CERTAIN PHYSIOLOGICAL EFFECTS OF STRETCHING OF THE SCIATIC NERVE.

By Dr. C. E. BROWN-SÉQUARD,
PROFESSOR OF MEDICINE AT THE COLLEGE OF FRANCE.

The cases of stretching of the sciatic nerve[1] recently published by Drs. Debove and Gillette have called my attention to this subject. My first experiments were made to ascertain what change, if any, would be produced by that operation on the loss of feeling experimentally produced in animals by the transversal hemisection of the dorsal spinal cord. It is known that I have shown long ago that in guinea-pigs, after such lesion, there is a decided hyperæsthesia, with considerable paralysis in the posterior limb on the corresponding side, while there is a marked degree of anæsthesia (and even sometimes a complete loss of feeling) in the posterior limb on the side opposite to that of the lesion. In rabbits there is nearly the same result obtained from the same operation, while in dogs hyperæsthesia is generally less, and anæsthesia is very rarely as complete as we often find in guinea-pigs.

On eleven guinea-pigs, after having divided transversely the right lateral half of the spinal cord at the level of the tenth dorsal vertebra, I ascertained that there was the ordinary effects of such a lesion on the two hind limbs. I then stretched the upper part of the sciatic nerve in all of them on the left side—i.e., the anæsthetic side. In one of these animals immediately after, in two of them a few minutes later, in two others half an hour after, and in three others much later, I found a considerable return of sensibility in the limb operated upon. Of the three other animals two remained as much anæsthetic as they were before the stretching, and one had only a very slight return of sensibility. I must say that in two at least of these last three guinea-pigs the knife had divided transversely very nearly two-thirds of the spinal cord. In several of the eight animals which had a great increase of sensibility where anæsthesia had existed (the left hind limb) there was observed a decided hyperæsthesia. Another remarkable effect was ascertained: the hyperæsthesia of the right posterior limb soon increased after the elongation of the left sciatic nerve.

On rabbits I have obtained much less clear results; the experiment, however, in one instance out of three, gave similar results to those obtained in eight guinea-pigs out of eleven.

Till now I have made a similar experiment only on one dog. The result in this case is a most remarkable one. The right half of the cord had been divided at the level of the tenth dorsal vertebra. There was in the right hind limb a moderate degree of hyperæsthesia, with an incomplete paralysis. In the left hind limb there was a considerable, almost complete, anæsthesia. Hardly did the dog feel the section of the skin, cellular tissue, and muscles, when I laid bare the left sciatic nerve. The same lack of feeling was evident when I stretched that nerve. Almost immediately after this operation pinching of the toes showed hyperæsthesia. This morbid increase of feeling went on increasing, and after twenty-four hours reached a degree which I have very rarely seen in dogs after any lesion. At the same time that these changes from anæsthesia to excessive morbid sensibility occurred the hyperæsthesia which existed in the right hind limb after the hemisection of the cord increased also, and in such a manner that its degree constantly exceeded that of the left limb. The stretching of the left sciatic nerve produced, therefore, in the two hind limbs (and I ought to say in all their parts) a considerable increase of sensibility. Another effect of the elongation of the sciatic nerve in that dog and in the other animals is a marked degree of paralysis in the limbs operated upon. There is, then, in those parts this striking contrast, that the same cause which produces an increase of sensibility simultaneously produces also a considerable diminution of voluntary motion.

It might be supposed that the stretching of the nerve alters in some way its structure, and that this local alteration is the cause of the two effects (on sensibility and voluntary motion) which I have mentioned. That such a cause has some share in those effects I consider as probable. But a great part of them, at least, as is proved by the following facts, depends on an influence of the irritation of the sciatic nerve on the spinal cord, then placed in a special organic condition.

1. In the experiments above described the return of sensibility and the appearance of hyperæsthesia, where anæsthesia existed, are found in the limb operated upon, not only in the parts receiving fibres from the sciatic nerve, but also and as much in parts having only fibres from the crural nerve.

2. In an experiment on a guinea-pig, the division of the right lateral half of the spinal cord was made in the cervical region (at the level of the third vertebra). After having ascertained that there was considerable anæsthesia in both limbs on the left side and hyperæsthesia in the right ones, I stretched the left sciatic nerve. The results were quite striking: not only the left hind limb, but also the left anterior limb soon became hyperæsthetic. On the right side both limbs soon acquired a greater degree of hyperæsthesia than that which had previously existed.

3. In guinea-pigs, whose spinal cord was normal, I have stretched one of the sciatic nerves. The effects of stretching have then been different from those of the previous experiments. The hyperæsthesia produced has been less than in animals having had a hemisection of the cord, and there has been also very much less paralysis produced. In the preceding experiments, as well as in these last, I have found a marked vaso-motor paralysis in the limb whose sciatic nerve had been stretched.

I do not intend to discuss now the questions of usefulness and dangers of stretching the sciatic nerve in cases of locomotor ataxy. I will only say that much simpler means of treatment may prove as beneficial as that operation. My object in publishing this short paper is simply to point out the great power that the irritation of the sciatic nerve, when drawn and elongated, possesses, as shown so conclusively by the considerable dynamic changes produced in the properties and functions of the spinal cord in the experiments I have related.

Paris.

---

[1] It is as a means of treatment against locomotor ataxy that the sciatic nerve was stretched in these cases. The operation produced very favourable therapeutic effects.

EPITOME OF A PAPER ON THE NATURE AND RELATIONS OF THE DISEASES OF THE EAR.[1]

By ROBERT SINCLAIR, M.D.,
PHYSICIAN AND AURAL PHYSICIAN TO THE DUNDEE ROYAL INFIRMARY.

Introduction.—Briefly stated, the objects of this paper are to show that the human ear is subject to the same fundamental laws of physiology and pathology as the rest of the organism; to demonstrate the application of general principles of therapeutics to the diseases of the ear; and to counteract the tendency to hedge aural surgery round with artificial distinctions which have a tendency to scare the general practitioner from intruding in what he too often regards as the sacred ground of a few specialists.

The Nature of the Majority of Ear Diseases.—At the threshold of an inquiry concerning the nature of the diseases of the ear, we are met by a fact which greatly simplifies our investigation. An overwhelming majority take their origin in inflammation, and preserve the inflammatory character more or less throughout their whole course. Of 500 cases recorded by Dr. St. John Roosa of New York, 429 were inflammatory; of 600 cases recorded by Dr. Turnbull[2] of Philadelphia, 432 were inflammatory; of 1500 cases treated at the Cork Ophthalmic and Aural Hospital, 1097 owed an inflammatory origin.[3] That is to say, as nearly as possible 75 per cent. of the persons who suffer from ear diseases suffer from inflammation of some portion of the ear.

The Importance of the Diseases of the Middle Ear.—Beyond all question the diseases of the auditory apparatus which occur most frequently, and possess the greatest interest for the practitioner, are the inflammatory affections of the tympanum or middle ear. In no other class of ear diseases has so much mischief been worked by apathy on the one hand, and on the other by officious meddling, and in none can we see more conspicuously the good results of a rational comprehension of well-known pathological changes, and the timely application of sound therapeutical principles. For practical purposes we may consider the middle ear as consisting of the membrana tympani, the tympanic cavity, the mastoid cells, the chain of ossicles, and certain muscles, vessels, and nerves. We have here, in a very limited space, a set of delicate structures performing important functions, easily disturbed from the standard of health by a variety of causes, and attaining increased importance from their contiguity to such vital parts as the labyrinth, the internal jugular vein, the internal carotid artery, the dura mater, and several venous sinuses of the brain. One may be excused for thinking that, even if no alarm is felt for the tympanum itself when attacked by inflammation, its anatomical neighbours might well command respect. Yet how often does the well-educated practitioner content himself with uttering a few commonplaces about the benign operations of nature, applying a blister to the mastoid process, and prescribing those admirable tonics, cod-liver oil and iron, while ulceration is quietly working its way among the structures of the tympanum, into the internal carotid artery or the sinuses of the brain, or laying the foundation for hopeless destruction of the labyrinth.

Acute Inflammation of the Middle Ear demands, perhaps, more than any other disease of the organ, the best care and skill of the family doctor. In a certain number of cases, inflammation of the external meatus which has arisen from cold, damp, furunculus, accident, or injudicious surgical interference, is propagated through the membrana tympani to the tympanic cavity. But it is much more commonly due to extension from the pharynx in scarlet fever, quinsy, diphtheria, measles, small-pox, whooping-cough, pneumonia, bronchitis, influenza, syphilis, and from the use of an instrument that should be banished from all well-regulated consulting-rooms—the anterior nasal douche. When originated in this way, the inflammatory action travels along the Eustachian tube, which, you know, is the channel designed by Nature for maintaining a due equilibrium between the atmospheric and tympanic air, and for draining superfluous mucus from the tympanum. When all the parts concerned are in a normal condition it admirably serves both these purposes. But, as I have already hinted, it serves also as a channel for conducting morbid actions from the pharynx; and when we remember its shortness (it is only about an inch and a half in length in the adult), and the continuity of its mucous membrane with that of the pharynx, it is far from strange that it should do so. If, however, morbid processes are easily conveyed along the adult Eustachian tube, how much more easily and rapidly must they traverse that of the child. Its still greater shortness, its less distinct isthmus, its great width in the middle and at the tympanic orifice, all facilitate the spread of inflammation to the tympanum; while its narrow pharyngeal opening and its almost horizontal position might be expected to offer a less easy exit for the escape of effused fluids than is allowed by the obliquely placed adult tube, with its wide pharyngeal orifice.

But there is still another way in which acute inflammation of the middle ear arises, very frequently, it is to be feared in children during the process of dentition, and which has been clearly demonstrated in a work unrivalled for originality, grasp, and suggestiveness, by any recent contribution to aural literature. I mean the work of Dr. Woakes[4] of London, who, though now a specialist, was for nearly twenty years of his life a general practitioner in Bedfordshire. Dr. Woakes has clearly shown how vaso-motor impressions may be rapidly conveyed from inflamed gums to such a distant and apparently unconnected, but really correlated, structure as the membrana tympani, and subsequently to the tympanum itself, through the medium of the otic ganglion, which has direct communications with the inferior dental nerve and the nervi vasorum of the tympanic branch of the internal carotid artery. The direct connexion of this branch with such a large trunk as the internal carotid offers a very favourable opportunity for its speedy and extreme dilatation, and the anastomosis of the vessels of the membrana with those of the tympanum itself rapidly produces inflammatory action in this organ. We have here the solution of the mystery which must have time after time perplexed every family practitioner and baffled his therapeutic resources. I refer, of course, to that large class of cases in which children, during dentition, develop what are vaguely termed "head symptoms," obstinately refusing to come under any of the ordinary descriptions with which we are familiar in text-books, and which are relieved on the discharge of pus from the external meatus. Dr. Woakes' description of this condition is so admirable and life-like that no apology is required for asking your attention to it for a moment. "The troubled face, the resting of the head on the nurse, the thrill of agony which passes across its features, accompanied with piteous cries or shrieks when its position is moved, especially if this be done suddenly, and more than all the constant raising of the little hand to the side of the head—no one who has watched these symptoms will fail to connect them with the most agonising of all the sufferings of early life, earache."[5]

I have no time to do justice to the close reasoning and observation which characterise every page of this work; but I hope I have said enough to induce you to devote many pleasant hours to its study for yourselves.

The exanthem which is mainly responsible for the production of acute inflammation of the tympana is unquestionably scarlet fever. I am not aware of the existence of statistics showing the exact proportion in which ear inflammations occur in any large number of consecutive cases of this fever. At some future time, when opportunity arises, I hope to obtain reliable figures on the subject. But it has been sufficiently proved that a very large number of cases owe their origin to scarlet fever, and, for want of proper care, drift into hopeless chronicity and deafness; and it is to be feared that no small share of the *immediate* mortality of this fever is due to tympanic inflammation and its sequels. These facts contain hints which should not be disregarded in the exigencies of general practice. While no medical man would dream of pronouncing the kidneys of a scarlet fever patient free from disease without making careful and repeated examinations of the urine, able and experienced practitioners too often act and think as if the tympana were not, like the kidneys, specially liable to inflammation in the course of this common exanthem. If the profession at large would only keep in mind the pregnant fact that "every congestion of the lining membrane of the tympanum is a periostitis, and every ulceration of it a caries of the osseous walls, that may lead to the most serious consequences,"[6] many lives would be saved, many useful ears would be spared, and deaf-mutism would become a rare exception.

ON THE NATURE AND SEQUENCE OF THE CARDIAC AND VASCULAR CHANGES IN INTERSTITIAL NEPHRITIS.

BY BRYAN C. WALLER, M.D., F.R.C.S. EDIN.,
LECTURER ON PATHOLOGY IN THE SCHOOL OF MEDICINE, EDINBURGH.

THERE is perhaps no topic within the whole range of medical literature which has excited more interest, provoked more investigations, and elicited more diverse opinions than that of interstitial nephritis. The various books and papers dealing with the subject would of themselves constitute a small library; and one might well begin to hesitate before adding to their number. Yet the summary in THE LANCET for December 18th, 1880, of an article by Sotnitschewsky, in a recent number of Virchow's *Archiv*, leads me to think that a few remarks on the connexion of interstitial nephritis with hypertrophy of the heart and disease of the arteries may not be deemed out of place from one who has devoted much attention to the subject, and has had the opportunity of examining an extensive series of specimens.

During the past five years I have carefully examined forty specimens of ordinary interstitial nephritis, comprising every stage of the lesion, and also five cases of glomerulo-nephritis consequent on scarlatina, making altogether forty-five specimens of interstitial changes. Out of these forty-five specimens, the condition of the heart, and that of the arteries in other organs, was examined in twenty-six. In the other nineteen specimens the examination was limited to the kidney alone.

I shall first consider the arterial changes visible in the kidney itself. These were exhibited in a greater or less degree by every one of the forty ordinary specimens. In the five cases of glomerulo-nephritis the arteries were invariably normal. Large numbers of leucocytes had migrated through their walls, and collected in great quantity in the peri-vascular connective tissue; but the coats themselves constantly presented a natural appearance. No germination of muscle nuclei in the middle coat, or hyaline degeneration of the intima, as described and figured by Klein (Trans. Path. Soc., 1877), was to be seen in any of them. The tunica adventitia was unthickened and natural, though the peri-vascular connective tissue was crowded, as just mentioned, with emigrant cells. In three of these cases I examined the arteries of the spleen, and those of the pia mater in two. All were natural; the only instance of alteration being a merely incidental condition of incipient waxy infiltration of the splenic corpuscles, which in one specimen were stained rose-pink here and there by a dilute solution of methyl-aniline violet (350 N. Lauth.). In this case the liver also was slightly waxy. The heart was examined in three instances, and found normal. In two cases the examination was limited to the kidney itself.

All these cases of glomerulo-nephritis were rapidly fatal. Their freedom from arterial and cardiac change seems to point either to a relation of cause and effect between the renal mischief and the alterations in the circulatory system in the ordinary variety of interstitial nephritis, or else to a common cause, acting in both directions, but affecting the heart and arteries at a later period. As we shall presently see, hypertrophy of the heart and changes in the coats of the arteries are very frequent in cases where the kidney lesion has evidently lasted a considerable time; while in speedily fatal cases they are nearly as constant in their absence, for the simple reason that they require time for their development, and this time has not been allowed.

In the forty ordinary cases the following vascular changes were observed:—In the earlier specimens the tunica adventitia was perfectly normal and unthickened, as could be conclusively proved by picking the arterioles from their surroundings with fine needles. The connective tissue distributed with the small arteries was increased in almost every instance, sometimes very markedly. In unstained specimens this increase in the perivascular tissue presented very much the appearance of thickening of the adventitia proper; but by the use of picro-carmine (1 per cent. solution, Ranvier's receipt), the distinction between the two became very apparent. In most of the more advanced specimens the adventitia was likewise normal and unthickened; but in some instances the fibrous increase going on in the connective tissue around had involved the adventitia also, which had thus become blended with the increased spurious adventitia or perivascular tissue. This was only seen in the most advanced cases of all, and was evidently an entirely secondary process.

It will thus be apparent that my series affords no support to Sir W. Gull and Dr. Sutton's theory of "arterio-capillary fibrosis." In my lately published monograph on Interstitial Nephritis, I have dealt with this subject at some length,[1] and have arrived at the conclusion that the evidence in support of the existence of an arterio-capillary fibrosis is insufficient. Out of the series of cases quoted by Gull and Sutton in their original paper (Med. Chir. Trans., vol. lv.) there were only twenty-six (if my memory rightly serves me) in which the kidneys were granular; while in my forty-five cases of undoubted interstitial lesion I have never encountered a single instance of any appearance in the outer coats which I could conscientiously term true "arterio-capillary fibrosis." The thickening of the adventitia above-mentioned was only seen in the most advanced specimens, and the inference, therefore, appears irresistible that far from constituting the essential morbid condition, it is at most a secondary, and very far from universal consequence.

I have much pleasure in stating that I can adduce the testimony of facts in support of Dr. Johnson's statements relative to the hypertrophy of the middle coat. Differing as I am compelled to do by the evidence of my specimens from this renowned authority on almost every other point, I have found the most undoubted instances of thickening of the circularly arranged muscular coat. I dissent, however, from Dr. Johnson with regard to the presence of an inner longitudinal muscular layer, for I consider that that which he so designates (Med. Chir. Trans., vol. xxxiii., p. 114; vol. lvi., pp. 149, 150; Trans. Path. Soc., p. 384, 1877) is merely the thickened and proliferated intima. For a series of comparative measurements of the several coats in a number of normal and interstitial arteries, I must refer to my monograph above quoted. Suffice it to say that I can entertain no reasonable doubt as to the reality of the muscular hypertrophy, which I believe to be a true one, firstly, because the muscle nuclei of the hypertrophied portions are increased in number, and, secondly, because it appears to be the rule that the more advanced the specimen, the more marked is the muscular hypertrophy. Now, hypertrophy of muscle cells is a gradual process, and we should accordingly expect to find it most marked in the oldest specimens. That it usually is so I have succeeded in satisfying myself, though three of my cases were exceptional on this score. In these, however, the tunica intima was greatly thickened, a circumstance often seen in connexion with atrophy of the muscular coat.

The muscular elements generally appeared quite normal, save for the increase in their numbers. I have never seen anything of the nature of fatty degeneration of the muscle nuclei, nor have I ever seen oil globules inside obliterated vessels in the stage of kidney contraction. As my use of osmic acid as a staining reagent was constant, I cannot think that anything of the sort could have escaped my minute and repeated scrutiny.

In some few cases I have encountered an unquestionably atrophic state of the middle coat. The atrophy was not nearly so frequent as the hypertrophy, and in almost every instance was accompanied by great thickening of the tunica intima. In the atrophied portions the muscular coat appeared more homogeneous than natural, and its nuclei were indistinct and occasionally entirely absent.

The muscular hypertrophy varied much in different specimens, and even in different arteries in the same section. In some of the earlier forms it did not appear to exist, while in others it was already perceptible. Almost all the later cases presented typical examples. In two specimens of advanced granular change the appearances were sufficient to convince the most sceptical. The microscopical sections from these two kidneys are now in the museum of the University of Edinburgh, in common with those from nearly two-thirds of my entire series.

---

[6] On Conservative Aural Surgery, p. 4. By J. P. Cassells, M.D.

[1] An Investigation into the Microscopic Anatomy of Interstitial Nephritis. Edinburgh: E. and S. Livingstone.

In thirty-seven out of the forty cases there were more or less obvious indications of changes in the inner coat. Even in the three remaining cases I should not like to say positively that its thickness was perfectly normal. I accordingly consider certain changes in the tunica intima, which I am now about to describe, as practically constant features, in at least all the later and a large percentage of the earlier forms of the disease.

In the more illustrative cases the tunica intima was found to present appearances substantially identical with those described by Heubner under the name of Arteriitis obliterans, and by Thoma under that of Fibrous endarteriitis.

In the earliest examples the inner coat merely appears thicker than normal, and evinces a tendency to become fibrous. In more advanced cases the lumen is considerably narrowed, but its sides are still smooth. Viewed in transverse section, the inner coat is many times its natural breadth, and contains round cells, spindles, and fibres, with a number of wavy lines, which represent the elastic laminæ of the inner coat separated from one another by the proliferative process. Small vessels are sometimes formed for the nutriment of the thickened tunic. A drawing by Dr. Barlow in the Pathological Society's Transactions for 1877 (Plate XV., Fig. 1), representing a syphilitic artery, will convey a pretty fair idea of the state of the intima in the arteries of many interstitial kidneys. This stage is represented in Plate V. of my monograph above quoted.

In the most marked cases, the inner coat is greatly thickened and the lumen very much reduced, or even entirely abolished. At this stage the thickening is principally fibrous, though a few round cells and wavy lines may be visible, as in the preceding one. The character of the thickening is coarse and ragged, something like cocoanut matting. The sides of the lumen, if it still exists, are rough and splintery, and present no trace of epithelioid lining. When the artery is completely occluded, that part of the resulting solid cylinder which represents the intima is seen to consist of more or less regular concentric rings, when viewed in transverse section. These rings are dense, and are composed of closely aggregated fibres and spindles, with very few round cells.

In other instances the thickening is of a fibrous type in the earlier stages. It varies much in degree in different specimens, being as a rule most marked in the more advanced, though one of the most beautiful examples was seen in a comparatively early specimen, the surface of which was but slightly granular, and the size little diminished, though the capsule was strongly adherent, and the interstitial changes in the cortex very visible under a power of thirty diameters. In this case the thickening was cellular rather than fibrous.

(To be concluded.)

CASES OF OBSCURE POISONING.

BY J. HAWKES, M.D.

THE following cases appear to me worth recording, not so much for the interest attaching to them in a purely medical point of view, as for the additional importance they derive in their bearing on forensic medicine.

I was hastily summoned on the morning of December 18th last, about eight o'clock, to examine the bodies of two elderly persons, man and wife, who had been discovered a short time previous lying beside each other in bed, in a state of profound insensibility. The husband, who occupies a small farm on which he resides with his wife, but with no other occupant of the house, had been missed from his accustomed work earlier in the morning, and the bailiff, after seeking him in vain, mounted a ladder against his bedroom window, and having broken a pane of glass, perceived the two bodies lying together as above described. On entering the room, which was of good size and airy, with an empty fireplace, I found the man and his wife lying in a natural position, comatose and breathing stertorously. The husband, a strong-made man, about sixty years of age, was pallid, his eyes closed, jaws clenched, surface of body warm, pupils moderately contracted, insensibility perfect. Pulse 98, full and rather strong. His wife was ghastly pale, jaws firmly clenched. Salivary foam issued from the lips, body of natural warmth, pupil of left eye contracted, right eye blind from old disease; the cheeks puffing out at each expiration, accompanied by stertorous breathing; pulse weak and irregular. No explanation could be afforded by anyone of the state in which they were found. I procured at once some mustard and warm water, and proceeded to administer it by teaspoonfuls placed between the teeth. The woman's mouth was, however, so firmly contracted that it was necessary to thrust the spoon through a cavity where a tooth had been removed on one side. When several spoonfuls had been given without any decided effect I directed some strong coffee to be made, and continued the exhibition of this, giving it as well as the solution of mustard for a quarter of an hour. The temperature of the man's body had now become raised, and his pulse full and bounding, the state of the pupils and insensibility remaining as before. In the woman no perceptible change had occurred. I had meanwhile examined the contents of the apartment, and found a box of pills marked "dinner pills," a small 2-oz. bottle labeled "balsam of aniseed," and an ounce phial half full labeled "laudanum—poison." Having obtained the assistance of two farm labourers I caused them to move the man's body, and lift it about the room in the erect position, the lower limbs dragging helplessly on the floor. His face, however, assumed a hue so cadaverous, his eyes glazing, that I had him placed back in bed. Leaving my pupil with directions to continue the coffee in teaspoonfuls every two or three minutes, I went home and prepared an emetic of sulphate of zinc and ipecacuanha, with which, in about an hour after, I returned. The condition of the woman was unchanged—breathing stertorous, cheeks puffing out as before, the jaws firmly clenched, and pupils contracted. In the case of the man his face had lost some of its pallor; the pulse continued full, and rather strong; breathing no longer laboured or stertorous. I at once gave the emetic in teaspoonfuls, the only effect it produced on the male subject being an exaltation of temperature, return of colour in the face, and wide dilatation of the pupils. The woman vomited small quantities of mucus, besides the medicine and coffee. Slapping with a cloth steeped in cold water caused in her corrugation of the muscles of the forehead; but the same application to the man aroused him more fully, and he was able to open his eyes and move his hand and arm. These remedies were continued through the day, and I saw the patients again late in the evening, when the husband was sufficiently recovered to recognise those about him and to speak, but could tell nothing of what had passed, and knew no cause to account for his state. The woman was still unconscious. She had vomited a second time; breathing stertorous at times; pupil less contracted; when addressed and shaken she opened her eyes and stared vacantly. On my visit the next morning the man was completely recovered, only feeling rather weak and exhausted; he declared himself entirely unable to account for the circumstance, and states he took only a little home-brewed ale previous to retiring to bed at nine o'clock, his wife coming to bed later. Her condition was still one of insensibility; breathing normal; pulse more regular; the colour of her face had somewhat returned. Ordered an egg beat up in sherry; tea at intervals, and milk. Visited the following day; found the husband dressed and downstairs; he still declares he knows nothing to explain the matter. The wife is now quite conscious and able to speak; breathing natural and healthy; colour of face normal; she denies having taken anything whatever in the form of laudanum or any other drug, and knows no reason for the insensible condition of herself and her husband.

Remarks.—These persons had been known to their neighbours as quiet, inoffensive, and orderly. Three months ago they were obliged to give up a farm, and had been since employed as care-taker of the farm where they now live. The woman had an illness six years ago, during which she was said to be "very low" and suffering from over-anxiety. She has been described to me as a peculiar, reserved woman, with something odd about her. The two lived happily together. The husband appears a very straightforward person; he still protests he knows nothing, and feels troubled at the thought of anything having been administered to him. The woman says she only used laudanum for outward application, never internally; she also affirms her utter ignorance of any drug having been taken either by herself or her husband. Some have conjectured the pair were drugged in order to plunder the house, but there does not appear any foundation for this surmise. From the presence of a phial of laudanum in the bedroom, and the symptoms of each case, I have no doubt whatever that opium was the poison taken.

St. Faith's, Norwich.

ADHESION OF THE PLACENTA.

By A. CUMMINGS AIR, L.R.C.P. Lond.

Morbid adhesion of the placenta to the uterine wall is fortunately of very unfrequent occurrence, but inasmuch as when it does happen it constitutes one of the most dangerous complications of labour, both from the great probability of its causing profuse post-partum hæmorrhage, and also from the risk of subsequent inflammation of the womb, the accurate diagnosis of this condition is of great importance, but according to the generally received teaching of modern text-books, it is very difficult, if not absolutely impossible. Thus Dr. Barnes in his lectures on obstetric operations says:—"You may suspect morbid adhesion if there have been unusual difficulty in removing the placenta in previous labours; if during the third stage the uterus contracts firmly, each contraction being accompanied by blood, and yet on following up the cord you feel the placenta still in utero; if on pulling on the cord, two fingers being pressed into the placenta at the root, you feel the placenta and uterus descend in one mass, a sense of dragging pain being elicited; if during a pain the uterine tumour do not present a globular form, but be more prominent than usual at the place of placental attachment." Dr. Playfair says:—"The cause of adhesion is often obscure, but it most probably results from a morbid state of the decidua, which is produced by antecedent disease of the uterine mucous membrane; then the adhesion is apt to recur in subsequent pregnancies. . . . . There are no very reliable signs to indicate morbid adhesion of the placenta previous to the introduction of the hand. And Dr. Churchill: "The diagnosis is in almost all cases impossible until the extraction is attempted; a strong suspicion will be excited, however, by the occurrence of uterine contraction, without extrusion of the after-birth. The previous history of the patient may in some degree confirm these suspicions; if she have suffered much pain in some fixed part of the uterus during pregnancy, it may have resulted from inflammatory action. Whenever we see a patient suffering thus we should always ascertain by the stethoscope whether it is in the situation of the after-birth, so that we may be prepared for the consequences at the time of labour."

I have met with several cases of morbidly adherent placenta, during the last fourteen years, and am inclined to believe that the diagnostic problem may be solved with almost absolute certainty; although from my experience being limited to so short a time I would desire to write with all becoming modesty.

The diagnosis is, I think, to be founded upon two symptoms, one of which is mentioned by Dr. Churchill, the other by Dr. Barnes—viz., that at some period of pregnancy, generally between the third and fifth month, a fixed pain, generally of a dull aching character, is felt over some part of the uterus; and this is converted into a severe *dragging* pain when the patient attempts to turn over to lie on the side opposite to the placental site; so much so that patients with an adherent placenta will never (as far as my experience goes) voluntarily lie on that side. This pain, I believe, to be of the same nature as that mentioned by Dr. Barnes, as being experienced when the cord is drawn upon; and is due to the dragging on the cord by the child when from gravitation it sinks through the liquor amnii.

Theoretically, it may be objected to this explanation that usually the cord is sufficiently long to prevent any such dragging; but I think it will generally be found that when the cord is long, it is twisted around the neck or limbs of the child, and produces the same effect as a short cord would.

No history of this dragging pain on the patient's turning to the side opposite to the placental insertion will be obtained, when the retention of the after-birth is merely due either to the inertia of a wearied uterus, or from irregular contraction; if there is hæmorrhage in either of these cases, one would be justified in trying the effect of cold, compression, &c., before introducing the hand, but in cases of true placental adhesion, trying these and similar means leads to dangerous loss of precious time.

ROYAL LONDON OPHTHALMIC HOSPITAL.

CASES OF OPTIC NEURITIS AND NEURO-RETINITIS.

(Under the care of Mr. Hulke.)

Roughly-sorted cases of optic neuritis, with which it is convenient to place congestive swelling of the optic papilla, fall into two classes, one in which the neuritis is associated with some intracranial disorder which stands in a causal relation to it, the other in which no such intracranial disorder is present: neuritis optica descendens and neuritis optica non-descendens. The wider interest felt in cases of the first class has attracted greater attention to these. They are of very frequent occurrence, and good examples often present themselves in the out-patient room. The implication of both the optic nerves is often not simultaneous in its onset, but one nerve is attacked before the other, so that the two nerves not unfrequently exhibit different phases of inflammation, and sometimes one nerve only is involved.

Case 1.— ——, aged eight, a weakly child, with double scrotal rupture, was sent up to the hospital from the east coast, absolutely blind. The right papilla optica was swollen and cloudy, and the veins were very turgid. The morbid appearances in the left eye were similar but somewhat less strongly marked. The pupils, notwithstanding that perception of light was absent, were not dilated, but small, and they contracted with convergence of the eyes. Six months previously the child had had very severe headache with retching. After a fortnight the right eye was thought to be blind, and soon after this the sight of the left failed. At the end of three months both were quite blind. When taken to the hospital he was free from headache, had not latterly retched, and he looked in good health.

Case 2.— ——, aged six years, was taken to the hospital by his mother, who for some time had thought his sight imperfect. Tried with Jäger's scales, he read No. 19 with the right eye, and with the left eye No. 2. The right optic papilla was swollen, and its veins very turgid. He was a delicate-looking child. In his second year he was noticed to frequently brush his forehead with his hand, as if he felt some uneasiness there, and about that time a knot (gumma?) appeared in the left biceps humeri, which disappeared later. About the same time he occasionally squinted, and he then began to have fits. These at first occurred at intervals of two or three weeks; they had continued up to the time of the visit, and had latterly become more frequent. From the description given of them the fits were epileptiform. His manner had become cold, wilful, and excitable.

Case 3.— ——, aged seven, when first seen at the hospital was quite blind. Both optic papillæ were swollen and opaque, and the retinal veins were very turgid and tortuous; within the opaque area they were lost to view wherever they dipped away slightly from the surface. The child was thought healthy until five months previously, when she fell ill. She was drowsy and listless, would not play, but lay about all day, and she often vomited. Soon the mother thought her sight failed. Three months after she was brought to the hospital the swelling and opacity of the optic nerves were replaced by whiteness, unnatural distinctness of lamina cribrosa and smallness of vessels—in short, by the signs of atrophy. The child's general condition was better.

CASE 4.— ——, aged fifteen, was led to the hospital. Both eyes were quite blind; their pupils were dilated and motionless. Both optic papillæ were swollen and opaque; the outline was hidden. Within this opaque area the arteria centralis was quite masked, and the veins greatly hidden; beyond it the vessels appeared very swollen and tortuous. During a year he had had great pain in the back of his head, which he spoke of as "a feeling of pressure as if I should fall; then my hands and my legs shook, and soon my sight grew dim."

CASE 5.— ——, a little girl, aged six years, quite blind, was taken by her mother to the hospital for advice. Both optic nerves were quite white; the details of the lamina cribrosa were abnormally distinct, and this up to the margin of nerve-disc, which was itself a frayed and not a clean edge; the vessels also were unnaturally small. The condition was plainly atrophy after neuritis. She was a plump, well-grown, healthy-looking brunette, never ill, the mother said, till six months before, when she became dizzy, and then had such excruciating pain in head that she never ceased screaming for twelve hours. She then had two fits, and after the second of these her left side was palsied, and her sight was gone. She had since then had two similar attacks, in which her neck was drawn towards her left shoulder. All these attacks were preceded by vomiting.

CASE 6.— ——, aged twenty-six, a servant, who through failing sight had lost her situation, applied at the hospital. Tested separately each eye read No. 1, the smallest type in Jäger's scale, but when both eyes were open the type was blurred and slightly doubled. Both optic papillæ were very swollen, and of an opaque stone-grey colour. This morbid condition passed across the margin of the papilla, hiding it for some way into the retina, especially in the left eye, and within its limits the arteria centralis was quite hidden and the veins much obscured. Beyond the opaque part, in the transparent retina, the latter were conspicuously turgid. In and at the outskirts of the swelling were brush-like extravasations of blood. She had, she said, for several weeks felt out of health—had giddiness, headache, and she often vomited. The pain was greatest in the left side of her head and in the occiput. She had tinnitus, loudest in the left ear.

ROYAL ALBERT-EDWARD INFIRMARY, WIGAN.

CASE OF COMPOUND DEPRESSED FRACTURE OF SKULL; SYMPTOMS OF COMPRESSION; TREPHINING; DEATH.

(Under the care of Mr. W. BERRY.)

FOR the following notes we are indebted to Mr. W. Roger Williams, the senior house-surgeon.

Gerard F——, a schoolboy, aged eleven years, was admitted on the morning of the 27th Nov., 1880, having sustained an injury to the head, under the following circumstances:—The lad was sent to shut a stable door, but the horse having got out, he seized the animal by a rope that was round its head. The horse, which was a young cart-horse, becoming restive and frightened, the boy let go the rope, and, running in front of the horse, tripped and fell. In attempting to get up one of the horse's hind hoofs struck him on the head. He was insensible for a moment or so, but then got up without assistance, and went home crying. There was no subsequent vomiting, but a fair amount of bleeding from the wound. Shortly afterwards he was able to walk to the infirmary, a distance of half a mile.

On admission he presented a semilunar scalp-wound, quite four inches long, with the concavity forwards. This wound was placed vertically above the right ear, and on a plane about an inch posterior to it, the lower end of the wound being level with the tip of the ear. The scalp tissues could be raised for about two inches in a forward direction, and in the front part of the wound, thus laid open the bones were exposed, denuded of periosteum. At this spot a fracture was detected, and it was soon made out that a spindle-shaped piece of bone, about an inch long and less than half that in its greatest breadth, had been separated from the lower edge of the parietal bone, and depressed to the extent of nearly a quarter of an inch; and in this position it was firmly fixed with its long axis horizontal. The lower limit of the depression was bounded by the serrated upper edge of the squamosal, and at this place the solution of continuity appeared to be of the nature of a separation along the parieto-squamosal suture. From the depths of the fracture blood welled up freely in a pulsatile manner, whence it was inferred that the posterior branch of the middle meningeal artery had probably been torn. The patient was a healthy-looking, intelligent lad, and had always enjoyed good health. At school he had done well, and was in a higher class than most boys of his age. He appeared to suffer very little from the accident, complaining only of a slight headache. There was no sign of hæmorrhage or escape of fluid from ear or nose. Pupils, respiration, pulse, and temperature presented no notable deviation from the normal. The detached scalp having been laid loosely down the wound was dressed with water dressing. The head was shaved, and an ice bag was applied. He was placed on milk diet, and ordered a full dose of compound senna mixture. He passed a good night, and next morning he was found reading the *Little Folks' Magazine*. He seemed disappointed when told he must give up reading. On the 29th continued as before, the only notable change being a rise of the evening temperature to 101·3° F. On the 30th the morning temperature was 99·6°, evening temperature 100°.

On Dec. 1st morning temperature 99·2°, evening temperature 103·6°; no other noticeable symptom. On the 2nd he was rather restless during the night. Morning temperature 101·2°, evening temperature 102·6°, and during the ensuing night he was restless and muttered in sleep.

On the morning of the 3rd he was talking to himself, but answered questions rationally, and knew those about him. Morning temperature 101°, evening temperature 102·4°. On the 4th, though he had been quiet during the night, it was found in the morning that he had passed urine and fæces in the bed. He was quite unconscious, and the breathing was rather stertorous. There was left facial paralysis. The left pupil was contracted, right dilated. The left hand and arm were constantly twitched. On tickling the soles of the feet neither of the lower limbs was moved, but at other times he occasionally moved both. Morning temperature 102·2°, pulse 80.

These symptoms remaining unaltered, Mr. Berry trephined at about midday. A little chloroform was administered. A horizontal incision about two inches long was carried forwards from the middle of the concavity of the crescentic scalp wound, and the resulting flaps were raised. A medium-sized trephine was then applied to the parietal bone immediately above the depressed fragment, and a circular piece of bone was cut out. There appeared to have been a trifling hæmorrhagic effusion into the dura mater, and some pus oozed from the lower part of the opening. Hardly any bleeding occurred, although the posterior branch of the middle meningeal artery grooved the piece of bone removed by the trephine. The projecting bridge of bone at the lower part of the wound was sawn through at each extremity and removed. The depressed fragment was then extracted, together with some splinters from the inner table. In doing this more pus escaped, making altogether more than a drachm. It seemed to come from the direction of the base of the skull. The flaps were then laid down, water dressing and the ice-bag being applied to the head. The symptoms previously noted underwent no abatement. Evening temperature 104°. On the 5th both hands twitched. When shouted at he would try to put out the tongue. After midday coma deepened, and he died at 6.30 P.M. quite unconscious. Morning temperature 103·8°. Unfortunately a post-mortem could not be obtained.

Remarks by Mr. BERRY.—This case is particularly interesting when taken in conjunction with the two cases of Mr. Godlee's in THE LANCET of Nov. 20th, 1880, page 806, and certainly shows the difficulty of laying down a hard and fast line as to the use of the trephine. Had the trephine been used as suggested by the house-surgeon, Mr. Williams, on his admission, suppuration possibly might have been prevented and recovery followed. I certainly could not look upon the case as a *punctured* fracture, therefore resolved not to interfere till symptoms of compression arose; and as the symptoms set in it was interesting to note the gradual rise of temperature. The failure of relief after using the trephine was, no doubt, due to pus finding its way to the base of the brain, between the dura mater and bone.

LOUGHBOROUGH INFIRMARY.

FIBRO-CYSTIC TUMOUR OF THE UTERUS; OPERATION; DEATH.

(Under the care of Mr. Arthur Eddowes.)

Mrs. F——, aged thirty-seven, was admitted on April 26th, 1877. She had had one child sixteen years ago, none since, and no miscarriages. The catamenia were regular. On admission she was suffering from menorrhagia (which had left her almost ex-sanguineous) and general dropsy. On May 24th, all the dropsy having disappeared, she was discharged.

About a year after this the abdomen began to enlarge on the right side, but she had no recurrence of the hæmorrhage.

On Sept. 9th, 1880, she was again admitted into the infirmary. Her body was poorly nourished, the complexion pallid, the appetite bad, bowels constipated, micturition frequent, but urine healthy. There was no œdema. There was a general pyramidal enlargement of the abdomen, the umbilicus was prominent, and there was enlargement of the superficial veins of the abdominal wall. A tumour was seen to move during inspiration and expiration. The recti muscles bulged forward when the patient raised herself from the recumbent position.

The girth at umbilicus was 38 in.; the right side at this level measuring 18 in. and the left 20 in. From the right anterior spinous process of the ilium to the umbilicus measured 4½ in.; from left, 9 in.; from the pubes to the umbilicus was 11½ in.; and from the sternum to the umbilicus, 8½ in. There was distinct fluctuation round the umbilicus to the extent of 10 inches. The fluid could not be displaced by firm pressure. There was dulness all over the abdomen, except the right flank. By vaginal examination the uterus was found to be anteflexed, mobile; the sound was easily passed, and the cavity of the uterus measured 2½ inches. Per rectum a large tumour, partly fluid and partly solid, was felt between the uterus and the rectum. This only moved slightly on movement of the sound whilst in the uterus.

A diagnosis was made of ovarian tumour of a large primary cyst, with multilocular base of gelatinous and fluid consistence.

The patient was subjected to a preparatory treatment for two weeks, during which her general health was much improved; and on Oct. 11th the bowels were emptied by an enema in the early morning. At 2.30 P.M. the patient was anæsthetised by Dr. Hutchison. Then, with antiseptic precautions, an incision five and a half inches long was made in the median line, midway between the umbilicus and pubes. As soon as the peritoneal cavity was opened, a cyst of a bluish colour protruded. On the patient coughing the cyst was forced still further through the opening. The hand was introduced into the abdomen and passed round the cyst, which was the size of a man's head; it was free from any adhesions except at its base, where it was connected to an enormous tumour of semi-solid semi-fluid matter occupying the lower part of the abdominal cavity and pelvis, and firmly adherent to the neighbouring structures. The primary cyst was then tapped, and about a gallon of greenish fluid escaped. The cyst walls being secured by the hooks of the cannula, the hand was again introduced, with a view to discover the position of another cyst, containing fluid. When this was done the trocar was exposed and the second cyst was punctured through the first, but out of this only about two pints of fluid escaped. The tumour not being sufficiently reduced in size by this, a third cyst was punctured by a second trocar, but only about an ounce of bloody fluid came out of this. The hand was again introduced, only to find the tumour slightly lessened in size, and chiefly of semi-solid matter, the whole mass being firmly adherent to the neighbouring structures. It was then found to be useless to proceed further, and a ligature of carbolised gut having been applied round the base of the cyst which had been emptied, the rest of it was cut off, and the base was returned into the abdomen. There was but slight hæmorrhage, and no escape of fluid into the abdominal cavity. The wound was closed by sutures, and dressed antiseptically. The patient was removed on to a bed in proper position, but she sank in three hours. A hypodermic injection was given to relieve pain when she rallied from the chloroform.

Necropsy twenty-one hours after death.—Behind the primary cyst was a semi-solid mass, which when removed weighed 12 lb. It sprang from the posterior part of the fundus of the uterus, being closely connected to it by a band of fibrous tissue, but not immovably fixed to the same. Besides the second large cyst which had been tapped, the mass contained numerous smaller cysts, the fluid contents of which weighed fully 2 lb. This large mass was situated on the upper part of the sacrum and lower lumbar vertebræ, being bound down by peritoneum. The walls of the uterus were hypertrophied to two or three times the size of their normal thickness. The cavity was normal in length. The left ovary was slightly enlarged. The right ovary was normal. In the wall of the uterus were several small fibrous tumours.

Remarks.—This case is interesting as showing the difficulty of diagnosing an ovarian cyst from a fibro-cystic tumour of the uterus.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

President's Address.—Epithelioma of Thigh.—Strangulated Hernia reduced en masse.—Rupture of Aorta.—Recurrent Sarcoma.—Scleroderma.—Chloasma.

A meeting of the Pathological Society of London was held on Tuesday, Feb. 1st, Dr. Wilks, F.R.S., in the chair. The proceedings were opened by an address from the President, in which he dwelt on the good work the Society had already done, and urged the members to work on in the old lines. A report of the Morbid Growths' Committee on a case of tumour of the thigh, previously exhibited by Mr. Hutchinson, was presented; a committee was appointed to report on two cases of skin disease of doubtful nature, shown by Mr. Morrant Baker and Dr. Cavafy.

Dr. Wilks remarked that he had not prepared any formal address, as he did not think the occasion demanded it. Thanking the Society for the honour done to him, he remarked on the advantage to the Society of changing the President every two years; in this way the risk of the work being conducted in a groove was prevented, and a new bias or influence frequently given. But if a permanent President were in any case desirable, he knew of no one so pre-eminently suited for that purpose as his predecessor, for it would be indeed difficult to determine which field of pathology possessed most interest to him, or had been most fruitfully worked by him. The chief difference discernible in the various Presidents had been that while some specially favoured a study of morbid anatomy by the exhibition of specimens of disease, others attached greater value to the increase in the circle of knowledge to be derived from discussion of pathological problems. He belonged to the former school, although he was fain to admit, from the interest always awakened by the formal discussions, that he was in a minority. To him the exhibition of specimens was of more value than the mere expression of opinion. It was well to remember that when this Society was founded there were other societies where such discussions might be held; but a want was felt, especially by younger members of the profession who were working at practically a new subject, of an opportunity to meet together to show, discuss, and organise their work. When he commenced his studies pathology did not enter into the regular curriculum, autopsies were made at the caprice of physicians to confirm some special point of diagnosis, but not as a matter of course. Morgagni, Andral, Cruveilhier, Rokitansky, and others had worked in it to a certain extent, but the results of their labours were not common knowledge. The great glory of this Society had been that it had stuck to morbid anatomy, and established, as it was, when this science was in its infancy, the Transactions of the Society would be found to be an epitome of the whole history of pathology, accounts of many of the best discoveries of the day being found in them. At first the diseases of the heart were studied, its variations being comparatively simple to follow, then more complex organs and complex diseases were investigated. Thus it was that first one case of enlarged glands in the neck and mediastinum was shown, then another, and then two or three more, until in a few years the whole history of lymphadenoma was elucidated. In the same manner all the pathological changes of Addison's disease were fought out here. And similarly the first specimen of visceral syphilis was shown almost with timidity, until at last the foundation of our present knowledge was firmly laid, and an undoubted proof of the great value of this Society's labours given. He used to hear that syphilis attacked only the outside of the body, or as far in as the eye could see or the finger reach, and because search had never been made into the condition of the internal organs, it was supposed that they were unaffected, and the discovery that this is not so had relieved thousands of patients and proves the close connexion between pathology and therapeutics. It has been said that therapeutics has a basis of its own apart from pathology, but, having thought over it for years, he had felt more and more strongly that this was not so. Could we imagine a mechanic undertaking to repair machinery who professed no interest in nor knowledge of the manufacture and normal working of the body? Neither could he see how pathology and therapeutics can be separated. Similarly the profession cannot be learnt at the bedside alone, for the meaning of the phenomena there observed can only be shown in the dead-house. It was therefore most important to work on without asking about results; truth is always of value, and there is no division into small and great in Nature; a man never sees the real result of any work or discovery. Our knowledge of the pathology of visceral syphilis had enabled us to relieve many patients, while the demonstration of the fact that in Addison's disease the organs at fault are hopelessly disorganised has saved a number of people with yellow skins from being poisoned with mercury. He suggested that advantage would arise from a record of facts in general pathology in the Transactions of the Society, especially a collection of a large number of cases showing the primary and secondary growths, say of cancer. The relation existing between the so-called heterologous and homologous cells was being worked out by histologists such as Dr. Creighton, but some of the same facts could be elicited by collecting all the cases occurring at the different hospitals in London. Thus it might be found that out of many hundreds of cases of cancer some tissues were never affected, or that primary cancer of the lung was so rare as to be doubtful altogether. It would be more difficult to know how far tubercular growths were the result of infection. We now know that abscess in the lung is pyæmic, while in the kidney it is not due to nephritis, but to some external cause; further knowledge of like kind would enable us to get rid of the idea that there are certain organs and certain diseases, and that each organ may suffer from each disease. We should find out what processes can, and what cannot, take place in the different organs and tissues. For instance, it might be that it would be shown that an alveolus of the lung could be only affected with exudation of lymph and hyperplasia, and that no other changes went on in it unless under the influence of extraneous matter. In conclusion he urged the members to work on along the old lines, and he felt sure that when the history of medicine in England was written the history of that Society would be written in letters of gold.

Messrs. BECK and GODLEE presented a report on a Tumour of the Thigh, shown at a previous meeting by Mr. Hutchinson. It was a variety of epithelioma differing markedly from the usual lobular form, and resembling somewhat closely the growth met with in rodent ulcer, to which the tumour was also allied by its very chronic course, but from which it differed in the fact that the lymphatic glands were affected.

Mr. MCCARTHY exhibited a specimen of Strangulated Hernia, which had been reduced *en masse.* A man, sixty-two years of age, was admitted into the London Hospital with a very large strangulated right inguinal hernia. Efforts at taxis failed, but finding no very urgent symptoms, and the man refusing all active interference, he was ordered to have an ice-bag applied. Next morning the house-surgeon reduced the hernia with great ease, but vomiting continued, and fulness was perceptible in the right groin. The man refused operation for three days; then, as the vomiting continued, he requested that it might be performed, but as the bowels had acted and the fulness in the groin had disappeared nothing was done. Next day the man died. At the post-mortem, in addition to the signs of acute peritonitis, a coil of gut one foot long, strangulated by a narrow ring, was found in the left iliac fossa. The sac of the hernia was found in the scrotum, and the upper part of it projected into the belly, and looked like the bowl of an egg-cup, and the upper edge of it was thin and ragged where the neck had been detached. Mr. McCarthy thought that nothing short of an abdominal section could have dealt successfully with this condition. He could not find a record of a similar case. — Mr. BRYANT asked if the strangling band were not an adventitious fibrous band rather than the real neck of the sac, which it was scarcely possible to imagine could be torn off. These anomalous cases are more common in congenital than acquired hernia; was this case congenital in its origin? — Mr. MCCARTHY quite accepted Mr. Bryant's view, but added that if the band were not anatomically the "neck of the sac," it was nevertheless torn off from that part, as the specimen showed. The hernia was an ordinary acquired oblique hernia. It was chronic, and the upper part, of the sac had been displaced upwards by the patient in his efforts at reduction, and thus, when strangulated, the neck was not fixed by the left hand during taxis in the ordinary manner.

Mr. MCCARTHY also showed a Ruptured Aorta from a girl aged twelve, who was knocked down and trodden on by a pony. She died in eighteen hours from collapse. The posterior mediastinum was found full of blood, the descending part of the arch of the aorta was seen to be ruptured apparently by the head of the third left rib, for this projected forwards more than any of the others, and when pressure was made on the front of the chest the head of the rib became still more prominent.—Dr. WILKS had often thought that we needed a full explanation of the way in which viscera suffer from external violence, for they all receive special injuries—the liver gets torn on its under surface, the heart at the back, and so on. No doubt it was in obedience to certain definite laws.

Mr. H. CRIPPS related the history of Two Cases of Recurrent Sarcoma in the practice of Mr. Willett at St. Bartholomew's.—Case 1. Male, aged nineteen. In 1879 had a small sarcoma removed from the ham. Four months later he returned to the hospital with a local recurrence of large size, for which amputation through the lower third of the thigh was performed. Three months afterwards he was again admitted very emaciated, with dyspnœa and hæmoptysis and a small tumour over the right side of the chest. He died nine months after the first operation. Post-mortem: A mass the size of the fist was found growing from the periosteum of the right fifth rib and extending back along the rib to the spine; the mediastinal, abdominal, pelvic, and deep inguinal glands were affected also, the growth from the latter having absorbed part of the hip bone.—Case 2. Female, aged forty. A year before admission a blister formed on the sole of the foot after a walk; it discharged blood and never healed. A growth here developed and was removed. In five months the tumour had recurred locally, and there was a hard mass in the groin, great emaciation, and eventually from 150 to 200 small nodules could be felt under the skin. Post-mortem: Both lungs beneath the pleuræ were thickly studded with small nodules; tumour growths were also found in each ventricle of the heart, beneath the pericardium, and in the femoral, inguinal, abdominal, and thoracic glands. All the abdominal viscera, except the spleen, were affected, and the intestines were thickly studded with small growths, the great omentum weighed five pounds. Sections of the periphery of the primary tumour showed an alveolar stroma with epithelial cells in the spaces (cancer), but the centre of the tumour and also the secondary growths showed all the characters of round-celled sarcoma. Mr. Cripps suggested that the distinctions between the various forms of malignant tumour were rather artificial than real; and he referred to the similarity of the secondary changes to those of pyæmia, in both diseases the secondary growths consisted of small round cells, but while the cells of the sarcoma showed power of growth, those in pyæmic abscesses are degenerated. These cases were also exceptions to the rule laid down by Mr. Butlin that sarcomata do not infect the lymphatic glands.—Mr. BUTLIN had seen both these cases; in the first case the pelvic glands were affected directly by a growth springing from the hip bone. The fact that sarcomata as a rule do not infect the lymphatics had been long shown, and by no means originated with him; but, on the contrary, he had shown that sarcomata in some situations, as the testicles, always infect the lymphatics; in others, as central growths in bone, very rarely; and in others again, as subperiosteal growths, less rarely.

Mr. MORRANT BAKER showed a patient with localised Scleroderma of the face and scalp. The woman, forty-five years of age, had suffered for four years. There was a very firm, brawny, irregular patch on the right cheek, tapering at each end, several raised pink hard nodules below it, very slight affection of the left side. On the scalp there were two hairless patches, smooth and dense, in one of which there was a small ulcer; the face was much seared, it was stated from caustics; the sensibility was not affected; the disease had not progressed during the last two years.—Mr. HUTCHINSON had never seen a case exactly like this, but he thought it approached in clinical features to lupus rather than scleroderma; for in scleroderma the patches, well defined at the commencement, have no tendency to spread, while here the nodules have enlarged. There was one undoubted spot of ulceration, and some forms of lupus ulcerate with extreme difficulty. He suggested that it somewhat resembled Hebra's rima scleroma. He had seen a case somewhat allied to it where an indurated patch on the cheek had followed a wasp-sting.

Dr. PYE-SMITH showed drawings of the earlier condition of a case of very extensive Scleroderma, exhibited early in the session by Mr. Hutchinson. The patches first formed coalesced; it was symmetrical at first, and did not follow the distribution of nerves, or bloodvessels, or parts of the skin, or particular regions. The general sensibility of the parts was lessened, but there were spots of very painful ulceration. Also another drawing of the early stage of the disease in a girl, showing the characteristic ivory patches.

Dr. CAVAFY brought forward a living specimen of Chloasma. The man, aged twenty-nine, suffered from jaundice for two months. The colour of the skin then deepened into a dark yellow-brown, the conjunctiva becoming normal. After nine months the general colour became lighter, and circular islets of healthy skin appeared, which are still increasing in number, and are most numerous on the upper parts of thighs and in the loins. He considered it due to nerve change.—Mr. HUTCHINSON thought, on a first examination, that it was a case of leucoderma.—Mr. M. BAKER concurred in this view, and suggested that it was often accompanied by pigmentation in the early stage. If his case was lupus, the disease existed in two forms in different parts.—The PRESIDENT requested Mr. Hutchinson, Mr. Baker, and Drs. Cavafy and Pye-Smith to report upon the two cases.

The Society then adjourned.

OBSTETRICAL SOCIETY OF LONDON.

AT the meeting on Wednesday, Jan. 12th, 1881, Dr. W. S. Playfair, President, in the chair,

Mr. DORAN showed an exfoliated portion of the Mucous and Muscular Coats of the Female Bladder. The patient was thirty-one years old, a primipara. After seventeen hours' labour, a large child, weighing 10 lb., was delivered by forceps, the bladder having been first evacuated. The perineum was ruptured, but was stitched up at once. There was difficulty in systematic use of the catheter, and cystitis appeared on the tenth day. The slough was passed on the twentieth day, and the patient afterwards did well.

Dr. GEORGE HOGGAN showed microscopic specimens and camera lucida drawings illustrating the Comparative Anatomy of the Lymphatics of the Uterus, being the material accumulated jointly with his wife. He demonstrated specially the lymphatics of the mucosa, which investigators had hitherto failed to discover. The superficial division of these ramified immediately under the epithelium. There were no true subserous lymphatics, but the vessels so-called were the lymphatics of the longitudinal layer of muscle on its outer surface. They appeared merely as small twigs, which crop up here and there and dip down again. In some animals, as the mare, no lymphatics are ever seen on the serous aspect of the muscle. The subserous lymphatics of the ovary were shown, that organ presenting a strong contrast to the uterus in this repect. On either surface of the circular muscles the lymphatics lay as dilated valvular sinuses parallel to the muscular bundles, being capable of great elongation on distension of pregnancy. The specimens were mostly prepared with silver and gold solution.

Dr. MATTHEWS DUNCAN exhibited two Ovaries removed by Dr. Lediard in a case of Double Ovariotomy in which there was suspicion of malignancy. A large amount of ascites had existed with the tumours.—Mr. KNOWSLEY THORNTON said that the specimens resembled one called a papilloma of the Fallopian tube exhibited at the Pathological Society by Mr. Doran. He thought it an interesting question whether in these cases the fluid was secreted by the peritoneum, or was a secretion in the interior of the tumour, which escaped by minute apertures.—Mr. DORAN mentioned other cases of ascites associated with still smaller growths, or with merely chronic inflammation of the ovaries, cured, in the latter case, by oöphorectomy.

Dr. EDIS showed a simple form of Syphon Douche, consisting of six feet of rubber tubing with a vaginal nozzle. By inserting the tube through the spout of a bath-can, and withdrawing it partially when filled, a syphon action was at once produced.

Dr. CHAMPNEYS exhibited the Uterus, &c., of a Woman, who died from septicæmia in consequence of a rupture of the upper and posterior part of the vagina, not, however, through the peritoneum. The child, which was born at the end of the seventh month, had been dead some time, and the labour was completed with apparent ease in four hours.—Dr. WILTSHIRE mentioned a case of laceration of the lef lower segment of the uterus where the patient had been rather precipitately delivered before help arrived. She recovered.

Dr. THOMAS CHAMBERS read a paper on "Complete Extirpation of the Uterus with both Ovaries, weighing ten pounds; recovery." Jane S——, aged forty-three, was admitted into the Chelsea Hospital for Women on May 24th, 1880. In 1870 she first noticed a lump in her right groin, which grew slowly for five years. After this menorrhagia commenced, and gradually increased. Pain and hæmorrhage were excessive, and she eventually became too weak to attend as an out-patient, and was remarkably emaciated. The tumour was freely movable from side to side, and was very soft and doughy, but without fluctuation. The pelvic cavity was unoccupied, the vagina drawn up into a cone, with the os and cervix, both small, in the centre. There was a periodical discharge of watery fluid through the vagina. Hence a diagnosis of fibro-cystic tumour was made. Medical treatment having proved of no avail, extirpation of the uterus was proposed to the patient, and she decided in favour of the operation. It was performed on June 2nd. The abdominal incision was extended to eleven inches. The broad ligaments were tied with silk at each side, a parallel clamp placed above the ligatures, and the uterus cut away. After a few minutes arterial hæmorrhage occurred from a large vessel, which was at once secured. The cervix was then transfixed by a double ligature, the clamp removed, the ligatures tightened, and the stumps replaced. By the twenty-first day the patient was convalescent, a free discharge of offensive matter from the vagina having taken place suddenly on the fourteenth day. The tumour proved to be a lobulated white fibroid, not fibro-cystic, and contained very large vessels.—Dr. HEYWOOD SMITH thought that the term hysterectomy should be limited to amputation of the uterus. He considered oöphorectomy safer than removal of the uterus when life was threatened by flooding and pain.—Dr. ROUTH had some years ago tabulated a number of fibro-cystic tumours as compared with pure fibroids of the uterus, and had found that in fibro-cystic disease menorrhagia was rare.

Dr. ROGERS related a case of Chronic Complete Inversion of the Uterus, successfully treated by sustained elastic pressure. S. B——, aged twenty-nine, had a child two years ago. Delivery was followed by great flooding, and menorrhagia has continued more or less ever since. On admission a tumour was felt in the vagina, as large as a turkey's egg; a ring encircled its neck, but the sound could not be passed more than a line or two above this. On April 28th Dr. Aveling's double-curved repositor was applied, and adjusted by Dr. Aveling. After twenty-four hours the strings were tightened, the patient being very comfortable. About sixteen hours later she felt great relief; something had given way, and the strings had become loose. On examination the repositor was found within the uterus high up, and was removed without difficulty. The uterus was completely restored.—Dr. AVELING stated that, since he had invented his repositor last year, five cases had been successfully treated by it.

Dr. MATTHEWS DUNCAN brought forward the subject of delivery in a case of Double Uterus. The patient was delivered naturally in her ninth pregnancy, but, as a portion of the chorion remained in utero, the hand was introduced into the uterus to seek for it. The uterus was then found to have two cavities, of which the child had been in the right. The left was smaller, but similarly shaped, having a rounded roof. In some previous pregnancies the patient had had copious losses of blood about the third and fourth months. The cervix was single and normal.—Dr. BRAXTON HICKS mentioned a case of pregnancy with double uterus and vagina. The author was called to examine a lady, pregnant four months, with a tumour in the right inguinal region, to ascertain whether the pregnancy were extra-uterine. On passing the vulva the finger came in contact with the edge of a firm septum, and it was obvious that an os uteri existed on either side. The uterus on the right side was manifestly pregnant, and of course more developed. Labour took place naturally at full term, and the abnormality was not noticed by the medical attendant.

Dr. W. S. PLAYFAIR read a supplement to a paper on Fibroid Tumours Complicating Delivery. Two cases were detailed by the author in the nineteenth volume of the Society's Transactions. In May, 1875, he was called to see a young married lady, on account of dysmenorrhœa. She had aborted without any known cause within three months of marriage. A large lobular mass was found, occupying Douglas' space, and thus placing the cervix forward. It had much mobility, and was diagnosed as a fibroid. Much anxiety was felt as to probable obstruction in labour, if pregnancy occurred. Soon after she did become pregnant, but the fibroid gradually rose above the brim as pregnancy advanced. Delivery took place naturally, and the fibroid afterwards diminished in size, and did not again descend into the pelvic cavity. The second patient, thirty years of age, was seen first by the author about the fourth month of pregnancy, in July, 1880. The greater part of the cavity of the pelvis was then occupied by a rounded, somewhat lobulated mass, rising above the pelvic brim. The cervix was pushed forward and upward, so as to be difficult to reach. It was decided to wait a while, and the tumour rose to some extent, but became stationary about Nov. 8th. Dr. Hicks met the author and Mr. Wells on Nov. 30th, and a vain attempt was made to push up the tumour under anæsthesia. On Dec. 1st premature labour was induced, with the intention that Mr. Wells should perform Porro's operation, if necessary. When the os was fully dilated the author made a final attempt to push up the tumour, and did so by using considerable force with the closed fist. The child was extracted by version, and was living.

CAMBRIDGE MEDICAL SOCIETY.

(Concluded from p. 177.)

Cases of Diabetes treated by Salicylic Acid.—Chemical Theory of Sudden Death from Chloroform.—Disease of the Skull in Congenital Syphilis.

DR. LATHAM read a paper on "Diabetes treated with Salicylic Acid." In discussing at a former meeting, in November, the action of salicylic acid in acute rheumatism he had suggested that the remedy acts by entering into chemical combination with the antecedents of the *materies morbi* of that disease, which is probably lactic acid, and that this and glucose might have a common origin. (See Note, *infra*.) In that case it seemed reasonable to suppose that the remedy should be of service in diabetes; and it had been given to six patients with variable success, but still with such results as seemed to warrant further trial and investigation. In the first case the sugar had entirely disappeared. Mrs. H——, aged fifty-three, consulted Dr. Latham in June last for great thirst and polyuria; her mouth was so dry and clammy that utterance was very difficult. She was passing seven or eight quarts in the twenty-four hours. These symptoms in a lesser degree had existed for two months, and she was losing flesh; urine, sp. gr. 1042, contained a large quantity of sugar. She was placed on a diabetic diet, with a moderate allowance of toasted wheaten bread, as she could not take gluten bread, and the effervescing citrate of ammonia was prescribed. There was marked improvement from this, but on Dec. 2nd she was still passing three pints of urine during the night; its sp. gr. was 1025, and contained a quantity of sugar. Fifteen grains of salicylic acid were now prescribed three times a day, and distinct improvement immediately followed. On Dec. 10th, sp. gr. 1015, but still containing sugar, as shown by the copper-test, and she was passing much less. On Dec. 22nd, sp. gr. 1017; no trace of sugar, and this, too, after having dined off beefsteak and plum-pudding a couple of days previously; but under the microscope were seen crystals of oxalate of lime and uric acid. She discontinued her medicine, and on Dec. 28th the specific gravity of the urine was 1016, without any trace of sugar to be found. She was passing, however, between three and four pints of urine in the twenty-four hours, and complaining of rheumatic pains in the joints, which had also troubled her for the first time in her life a few months before the diabetes was discovered. The second case was one seen in consultation with Mr. Carter. This case was complicated with the existence of a large swelling of the parotid gland and surrounding tissues with suppuration, under which the patient sank. But whilst taking ten-grain doses of salicylic acid, the amount of urine diminished from seven pints (sp. gr. 1035) on Nov. 7, to four pints (sp. gr. 1018) on Nov. 30th, and on Dec. 3rd, two days before his death, he passed five pints and a half (sp. gr. 1026), with only feeble traces of sugar. The disappearance of the sugar may have been due to the intercurrent disease, as is sometimes the case, and the dose of the remedy was small. The beneficial effect could not have been due to the chemical action of the remedy, but the coincidence is noteworthy. The third case was that of a lady, aged fifty, whom Dr. Latham had seen from time to time, and who for eighteen months had suffered from diabetes, associated with considerable headache, pains in the limbs, across the loins, and along the sciatic nerves, especially severe at night, and preventing her from sleeping. Various remedies had been tried to relieve the neuralgic pains, but with little success. On November 6th she came for advice, as the thirst was more troublesome, the nights were very restless, and had been so for some time, and she was very easily worried and disturbed. She was taking ordinary diet, though from time to time she had tried a restricted diet, generally with the effect of lessening the amount of urine, but increasing her general discomfort. She was passing four quarts of water daily, sp. gr. 1035, containing a large quantity of sugar. Without altering the diet in any way, salicylic acid was prescribed in fifteen-grain doses. On the evening of the 6th she took one dose and slept well, afterwards she took three doses daily. On the 7th she slept well and passed six pints of urine, sp. gr. 1030; on the 8th she passed four pints, sp. gr. 1037; on the 9th, three pints, sp. gr. 1041; on the 11th, two pints, sp. gr. 1037; on the 13th, five pints, sp. gr. 1034; on the 18th, three pints, sp. gr. 1032. She was then troubled with bad headaches and giddiness, &c., and the medicine was taken very irregularly, generally not more than one dose in the day, the sleep was indifferent, and the quantity of urine varied from three pints to three quarts; sp. gr. ranging from 1031 to 1037. On Dec. 6th she was placed on a more restricted diet, and took from that time two or three doses daily of the acid. The urine diminished, and averaged four pints daily; the sp. gr. diminished, and was generally below 1030; on Jan. 4th it was 1025. The three other cases are at present in the hospital. One on admission, on Dec. 1st, was passing four to five pints daily; sp. gr. 1036. He has taken twenty grains of salicylic acid three times a day, with meat, greens, eggs, tea and coffee, and eight ounces of wheaten bread, and passes now from forty to fifty ounces daily of urine with a sp. gr. averaging 1030, and has gained a few pounds in weight. A second, aged forty-four, on Dec. 10th passed 107 ounces of urine, sp. gr. 1045, when he was taking ordinary diet. Fifteen grains of the acid were given without any benefit until Dec. 13th. He was then placed on a restricted diet, with eight ounces of wheaten bread, and twenty grains of the acid had been given to him three times a day. On Dec. 15th he passed sixty ounces, sp. gr. 1050. The quantity and specific gravity varied, but his general health much improved, and on Jan. 4th he passed sixty ounces, sp. gr. 1033. The third case had only been in the hospital a few days. The man was passing about fifty ounces daily, sp. gr. 1042, and neither the medicine nor a restricted diet had as yet produced any improvement. He complained of very severe neuralgic or rheumatic pains in the legs, especially troublesome at night. Dr. Latham had not ventured in any of his cases to try the enormous doses which have been given in Germany (in the Medical Clinique at Kiel) in this disease, such as fourteen to sixteen grammes daily (about half an ounce), (see *Berl. Klin. Wochensch.*, 1877), for in the cases above recorded even sixty grains a day were quite sufficient to produce some of the physiological effects of the drug. That it is of use in this disease seems clear, but for what cases and to what extent must be matters for further investigation.

Dr. LATHAM then directed attention to the "Chemical Aspect of Sudden Death by Chloroform." He had recently suggested that the living representative of sarcosine is the hypothetical compound $(C_2H_5O)(CN)(H_2O)$, cyanate of ethyl + water, and that the cyanate of ethyl either in the living sarcosine or in some derivative from it combines with salicylic acid to produce salicyluric acid, &c, and that seemed to be in accordance with the views of Pflüger (Archiv, x., s. 337), who "has called attention to the great molecular energy of the cyanogen compounds, and has suggested that the functional metabolism of protoplasm, by which energy is set free, may be compared to the conversion of the energetic unstable cyanogen compounds into the less energetic and more stable amides. In other words, ammonium cyanate is a type of living and urea of dead nitrogen, and the conversion of the former into the latter is an image of the essential change which takes place when a proteid dies." (Foster's "Physiology," 3rd edit., p. 691.) Or may it not be, generally, that the cyanates and cyanides are the types of living tissues, the isocyanates and isocyanides of dead ones? In this way:—

$$(NH_4)(CNO) \text{ represents living} \;\ldots\ldots\ldots\ldots\ldots\ldots\ldots\; N\left\{\begin{matrix} CO \\ H_2 \\ NH_2 \end{matrix}\right. \quad \text{dead urea}$$

$$(NH_4)(CNO)(C_2H_5)(CNO) \text{ represents living} \;\ldots\ldots\ldots\; N\left\{\begin{matrix} CO \\ H_2 \\ NH_2 \end{matrix}\right. + N\left\{\begin{matrix} CO \\ \\ C_2H_5 \end{matrix}\right. \quad \text{dead kreatine}$$

$$(NH_2)(CN)(C_2H_5)(CNO) \text{ represents living} \;\ldots\ldots\ldots\; N\left\{\begin{matrix} C \\ \\ NH_2 \end{matrix}\right. + N\left\{\begin{matrix} CO \\ \\ C_2H_5 \end{matrix}\right. \quad \text{dead kreatinine}$$

Now, if this be so, may we not have here an explanation of some, at least, of the cases of sudden death which occur under the influence of chloroform? By means of chloroform, as was shown by Hofmann, the amides are converted into isocyanides; and if the inhibitory or coördinating chemical centre is weakened, so that the four molecules composing living kreatinine are loosely held together, the chloroform would act on NH_2 and C_2H_5, transforming the ethylamine into dead ethyl isocyanide—

$$(C_2H_5)(NH_2)+CHCl_3=3HCl+N\left\{\begin{matrix} C \\ C_2H_5 \end{matrix}\right.$$

$$\text{and } 2CNHO+2H_2O=2NH_3+2CO_2$$

Consequently,

$$\underset{\text{Living kreatinine.}}{(NH_2)(CN)(C_2H_5)(CNO)}+\underset{\text{Chloroform.}}{CHCl_3}+3H_2O$$

$$=\underset{\substack{\text{Ethyl}\\\text{isocyanide.}}}{N\left\{\begin{matrix} C \\ C_2H_5 \end{matrix}\right.}+\underset{\substack{\text{Ammonium}\\\text{chloride.}}}{2NH_4Cl}+HCl+2CO_2$$

If, then, in a person whose coördinating chemical centre is in a feeble state, blood charged with chloroform passes from the lungs to the heart, and at once through the coronary arteries comes in contact with the muscular tissue, one constituent of the muscle would be decomposed, and the transformed tissue would no longer respond to the nervous stimulus, but become a mere bag, into the right side of which the blood, from the pressure in the veins, would flow, and the patient die with a distended right ventricle.

Note by Dr. LATHAM. — In THE LANCET of Jan. 17th, page 97, I have tried to show that it is not improbable that salicyluric acid may result from the action of glycogen and alloxan in the presence of salicylic acid (assisted, it may be, by the pancreatic ferment). Pancreatic juice will convert glycogen into glucose, and glucose fermented with a nitrogenous body may be converted into lactic acid. Consequently, if salicylic acid be not present, the following changes may take place instead of those given on page 97:—

$$\underset{\text{Glycogen.}}{2(C_2H_5O)_2C_2O_3}+\underset{\text{Alloxan.}}{2(CN)(NH_2)(C_3O_4)} \quad +3H_2O$$

$$=\underset{\text{Carbonic ether.}}{(C_2H_5)_2CO_3} \quad +\underset{\text{Ethene cyano-hydrate.}}{2(CH_2OH-CH_2CN)}+\underset{\text{Oxaluric acid.}}{(NH_2)_2C_3O_4}+\underset{\text{Oxalic acid.}}{3C_2O_3.H_2O}$$

And under the influence of alkalies (see Fownes' Manual of Chemistry, 11th ed., p. 707)—

$$\underset{\text{Ethene cyano-hydrate.}}{CH_2OH-CH_2CN}+2H_2O=NH_3+\underset{\text{Paralactic acid.}}{CH_2OH-CH_2-COOH}.$$

The carbonic ether being either decomposed into alcohol and a carbonate, or uniting with oxalic acid to form oxalic ether, which with urea is decomposed into allophanic ether, alcohol and oxamide (see Watt's Dict., 1st Supplem., p. 89), oxamide and dilute phosphoric acid, which may be present in the blood, forming ammonium phosphate and oxalic acid.

Dr. LEES gave a demonstration of the series of Skulls collected by Dr. Barlow and himself from cases of congenital syphilis.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.

THE annual meeting of this Association was held on Wednesday evening, Jan. 26th, when the Treasurer announced that the finances of the Society were in a most healthy condition. The retiring President (Mr. W. A. N. Cattlin, F.R.C.S.) delivered an address "On the Imperfections of the Dentists Act, with Suggestions as to the Alterations required to protect the Interests of Qualified Surgeons." The following is a list of the newly-elected officers of the Society:—President: Mr. T. Edgelow. Vice-Presidents: Messrs. J. A. Baker, Samuel Cartwright, W. A. N. Cattlin, Francis Brodie Imlach, S. J. A. Salter, F.R.S., and Dr. John Smith, F.R.S. Ed. Treasurer: Mr. S. H. Cartwright. Honorary Secretary: Mr. J. Hamilton Craigie. Council: Messrs. Edward Bartlett, J. Fairbank, Francis Fox, C. Gaine (Bath), W. A. Hunt (Yeovil), W. D. Napier, W. G. Ranger, and Augustus Winterbottom.

STRUCTURE OF ANAL MUCOUS MEMBRANE.

To the Editor of THE LANCET.

SIR,—In reference to the description of the structure of the anal mucous membrane in last Saturday's LANCET (p. 187), allow me to say that Mr. Bickersteth has been in the habit of describing the "pouches" referred to in the paragraph, in his Clinical Lectures, for the past four years to my knowledge. He has, moreover, demonstrated the pouches by the introduction of a probe bent at one extremity into a hook. Not only does Mr. Bickersteth describe these pouches as playing an important part in the production of anal abscess and fistula, but as a source of irritation and distress owing to husks of corn and other substances lodging therein. I hold notes of two such cases. In addition, the division of the pouch or pouches is performed by Mr. Bickersteth by the aid of a hook-shaped knife—the cutting edge of which is within the curve of the hook.

Seeing that this subject is not mentioned in any of the books that I have consulted, it is worthy of more than casual publicity. Yours truly,

Liverpool. WALTER T. CLEGG, M.R.C.S.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 5, 1881.

WE have been twitted with taking a non-specialist view of the question of Lunacy Law Reform, and of being hampered by the traditions of THE LANCET. As regards the first part of this charge, it is only necessary to remark that if by "experience" is meant an intimate acquaintance with the business of hotel-keeping for lunatics, ignorance is such bliss that we would not willingly barter it for the knowledge our critics boast, and with which they are doubtless well furnished. If, however, "experience" may be taken to imply a close study of mental disease, and practical acquaintance with the active treatment and personal management of the insane, then we will not yield precedence to any "authority" who, unable or unwilling to argue the question of lunacy law reform on the basis of plain facts, seeks to raise a side issue. With reference to the traditions of THE LANCET, we will only observe that they are clearly formulated, and fully matured. They do not hamper us, because we are most fully persuaded that the views entertained by the founder of this journal, the late Mr. WAKLEY, and expressed by him in its pages, and in his place in the House of Commons, on the subject of the asylum system, and the working of the lunacy statutes generally, were pre-eminently sound, and, looking to the present state of the question, singularly applicable. Little remains for us to do beyond enforcing those views in their entirety. The leading features of this topic have been so little changed by the progress of events during the last quarter of a century, that the very language used in these columns more than twenty years ago accurately embodies the opinion we desire to express to-day.

"The public has ample confidence in the practitioners of medicine; it harbours an instinctive distrust of those whose vocation it is to combine the custody with the treatment of the insane. It must be regarded as a serious misfortune that any member of a liberal profession should be found acting in this double capacity. The medical proprietor of a private asylum will infallibly be looked upon as a composite individual, in whom the lodging-house-keeper, interested in filling his establishment, predominates over the physician, whose professional pride it is to cure his patients." We wrote thus in a leader on April 23rd, 1859. At the same time, we said, "It has been generally recognised that the inspecting capacity of the Lunacy Commissioners is quite inadequate. It is felt to be impossible for six Commissioners, visiting in pairs, to maintain a sufficiently minute and frequent supervision of the numerous private houses and their inmates, within their jurisdiction.......The plan proposed is to appoint 'medical examiners' for districts; their duties to be, to visit any patient received into a house in their district forthwith, on receipt of a notice of admission, and to transmit a private report upon the case to the Commissioners."

Mr. DILLWYN—whose labours in the cause of Lunacy Law amendment will ultimately be acknowledged as entitling him to the respect and gratitude of the profession and the community—has reprinted his Bill of last session, with a few small but not unimportant alterations, which we are glad to recognise as improvements. The initial proposition is to enable justices to provide for the accommodation of lunatics other than paupers. Clause 1 would extend the powers given by 16 & 17 Vict., chap. 97, secs. 46—52, so as to allow the justices of counties and boroughs to raise money for the provision of new asylums for paying patients, or the purchase of those that exist. This proposal has been opposed on the ground that it does not compel the taking over of all the existing asylums. Ultimately all asylums must be public institutions. The power of imprisonment *must* be withdrawn from private persons, and restricted to public officials acting in the name, and under direct responsibility, as agents, of the Government. We should entirely agree with those who object to the permissive nature of this clause if they took exception to it on the ground just indicated; but that is not the fact. The antagonism exhibited comes from the proprietors of existing asylums who are not unwilling to be bought out of their undertakings, more particularly now that the public are beginning to distrust them, but who are not so sure of the value of their properties as to feel confident that the justices will purchase them. Of course, if the private asylums were well up to the requirements of the day, and eligible from a business point of view, there could be little doubt of their sale, though the clause is left optional. We are not disposed to attach any great importance to this objection. There can be no question that the justices will buy where they can do so with a due regard to the public interests, and after the long spell of forbearance the proprietors and lessees of asylum property have enjoyed, they may well be content to abide the event. It is not graceful to stand in the way of reform with petty and selfish objections. Clause 2 provides that the proprietors of such asylums as may be purchased shall receive in addition to the value of their freeholds or leases, and other stock-in-trade, a "goodwill" not less than the yearly average profits of the establishment during "the three years immediately preceding the passing of this Act." In the Bill of last session the assessment was to be made on the basis of the average of three years preceding the sale. The present wording is better, as supposing the sale to be delayed there may be a serious disturbance of the averages of profits by the passing of this Act. Another important feature in the clause is a provision at the close enabling the justices to pay the vendors of asylum property in "bonds" issued under the authority of the Act 16th and 17th Vic., chap. 97, before cited. This will meet the convenience of those proprietors who would like to retain a monetary interest in the property, although no longer beneficially interested in the profits of the business. It will also obviate the need of borrowing money, except to pay off proprietors who are eager to realise. Clause 3 transfers private asylums and licensed houses in the metropolitan districts from the jurisdiction of the Commissioners to that of the justices. This is necessary to bring them fully under the Act. Clause 4 requires the provision of at least one asylum for paying patients, within each of the metropolitan districts within two years after January 1st, 1882. The time allowed strikes us as needlessly long, but this can be amended in Committee if deemed desirable. By Clause 5 the receipts from asylums are to be made a common fund, and any surplus in a district appropriated to the reduction of the rates levied for the maintenance of the pauper lunatics chargeable to that district. Clause 6 places private asylums, on becoming the property of the justices, upon the footing of public asylums as regards their government and administration. Clause 7 continues the "Medical Visitor to the justices" appointed under 8th and 9th Vict., chap. 100, but makes him virtually local inspector of *all* asylums without official connexion with either, and requires that he shall not be engaged in private practice, but permits him to hold any public appointment such as those of coroner and medical officer of health, or to be a professor at, or teacher in, any medical or scientific school. This is a great point gained for the independent and yet skilled supervision of the insane in asylums. There can be no difficulty in obtaining the services of medical men of position and repute for the post, and it will be a most important one, looking to the provision made in subsequent clauses of the Bill. Clause 8 enables the Committees of Visitors of Public Asylums to provide suitable accommodation for paying patients. Clause 9 requires that no lunatic shall be received into any asylum without an order granted by a Justice of the Peace. It also provides that the person signing the form of application to the justice shall be a blood relation within one or two degrees, or a solicitor acting for a person so related. One of the two certificates of insanity is to be signed by the Medical Visitor. This we hold to be one of the most important and salutary provisions in the Bill. It will give, if not a perfect, certainly a very strong, safeguard against abuses, and in every respect be most satisfactory to the great body of the medical profession and to the public. The same clause provides for the admission of urgent cases on a single medical certificate, but Clause 10 requires that in all cases of "emergency" notice shall be at once sent to the Commissioners in Lunacy and to the Medical Visitor, and that "as soon as possible after receiving such notice, the Medical Visitor shall visit the case and report forthwith confidentially upon it to the Commissioners in Lunacy." It must be manifest that this is an arrangement of the highest value, and looking to the advice we gave in 1859 (above quoted), we trust the visiting and reporting to be performed by the Medical Visitor will hereafter be extended to all cases received into asylums, thus securing that personal knowledge and supervision of the insane which the law as it stands does not provide. Clause 11 limits the operation of the order of admission made by a Justice to one year, and makes it determine with the notice of discharge of the patient. Clause 12 adopts substantially the provisions of the Scotch law in respect to voluntary patients, thus providing for the early treatment of mental disease, when a patient is self-conscious of the need of aid or protection and may yet be spared the development of actual disease. This is a very valuable and obvious amendment of the strangely imperfect lunacy system which finds favour on this side of the Tweed. Clause 13 provides that any person may obtain an order from a judge at chambers or a chairman of Quarter Sessions, a stipendiary magistrate, or a County Court judge—easily accessible officers—for the examination by two medical men of any lunatic confined in an asylum, with a view to his or her discharge. By Clause 14 the Commissioners in Lunacy are required to visit all houses, hospitals, and asylums at least *twice* in each year. Clause 15 gives the Commissioners power to order the removal of any patient in a private asylum to a public institution. Clause 16 provides for the appointment of a salaried chairman to the Board of Commissioners in Lunacy, and enables the Lord Chancellor to appoint two additional Commissioners, both being physicians. Among the schedules of the Bill, we would particularly call attention to that marked "F," which requires the signature of the Medical Visitor of the district to every certificate presented by a superintendent, to continue a judge's order from year to year. This will further strengthen the development of the Medical Visitor's authority as a local inspector of the *insane*, as distinguished from the Visiting Commissioners, who are practically travelling inspectors of *asylums*.

Such is a brief outline of the main provisions of Mr. Dillwyn's Bill. We shall hereafter have ample opportunity for the discussion of its proposals in detail, but, speaking now generally, it is a measure we most cordially approve and must warmly support.

The subject chosen by Mr. Lister as the theme of his address on first taking the chair at the Clinical Society was peculiarly well chosen, and dealt with in a manner worthy of the speaker and the Society and profession addressed. The value of the catgut ligature can be tested only by clinical experience, and there is no question of surgical therapeutics exciting more interest—and worthily so—at the present time than Mr. Lister's attempt to reintroduce an animal ligature. But Mr. Lister's Address shows, as pointed out also by Dr. Wilks in his address at the Pathological Society, how intimately all clinical study is bound up with pathological research, and what valuable aid it receives from chemistry and scientific philosophy, and as an illustration of these facts the Address is well worthy of study.

Mr. Lister acknowledges, as he was bound to do, that hitherto the catgut ligature has been uncertain in its action, and therefore not entirely trustworthy. Sometimes softening too soon and exposing the patient to the danger of hæmorrhage, it has at other times resisted too long the absorbent action of the soft tissues and induced local irritation. But these occurrences have been but the exceptions to the general success attending its use. With characteristic discrimination he foresaw that this irregularity in the changes undergone by the dead passive catgut would be explained by some differences in its physical or chemical characters, and with laborious research he endeavoured to find out the clue to this variation, and if possible to devise some mode of obtaining a ligature uniform in character and possessing all the qualities of the best specimens of catgut hitherto prepared. In this he states he has been successful. It has been rumoured for some time past that such was the case, but that Mr. Lister was hesitating to publish his mode of preparation until fully convinced that it was all he desired it to be. And those who know Mr. Lister best will feel most confidence that what he has now made public will bear the test of experience. We need not here refer to the treatment to which Mr. Lister subjects catgut, but must only point out that while simple, cheap, and rapid, it is warranted to produce a thread, supple, very strong, of which a knot properly tied holds without any slipping, and which is slowly but surely absorbed by the tissues, neither yielding too soon nor remaining too long. It may seem that this is "too good to be true," that unless there is some reservation to be made it is an exception to most if not to all surgical procedures. Lengthened experience can alone determine this point.

The artificial arrest of hæmorrhage is perhaps the greatest surgical triumph, and there is no landmark in the history of the practice of surgery on which we can look back with greater pride than the introduction of the ligature by Ambroise Paré. Since that time every competent practitioner has been armed with a certain means of arresting, at least temporarily, loss of blood from any vessel around which a thread can be passed. And if the tendency in late years has been rather to concentrate attention upon the failures attending the use of silk and hempen threads, we must not lose sight of the incalculable advantage they have proved during the last three hundred years. The proportion of failures has been small indeed, and if it be that to this generation of surgeons, and to Mr. Lister in particular, the honour of *perfecting* the ligature will accrue, we must not withhold our meed of admiration from that man who first conceived the idea of closing the mouth of a bleeding vessel by a constricting thread, and carried it out with a success which has been shared in by countless thousands in later years.

There is one feature in this communication of Mr. Lister's that will recommend it very widely. It is the fact that it is a simplification of one of the parts of his antiseptic treatment which is generally supposed by those who do not practise it to be too complicated. We doubt not that its author is fully alive to this consideration, and that he would welcome any method by which a like simplification could be made in his mode of dressing, while all its claimed advantages are retained, or made more certain. Another fact of importance is Mr. Lister's admission that the catgut ligature is not an integral part of his antiseptic treatment, but that it is of avail when that cannot be, or is not fully, carried out; it thus becomes generally applicable, and the value of Mr. Lister's work proportionately increased.

There is one part of Mr. Lister's Address, however, that leaves an impression of doubt upon the mind, and we refer to it with the more liberty as we have already stated our very high appreciation of its general value. And it is in reference to the lasting strength of the new catgut. Mr. Lister tells us that the large size will bear a strain of 13 lb. at least before breaking, which is more than can be employed by the unaided hands, and goes on to say that, after soaking for half an hour in blood serum at the temperature of the body, its breaking strain is only reduced to just over 11 lb. We confess that we crave for more facts in the same direction; what strain will it bear at the end of one, three, five, and twelve hours? If used only for clean vessels in a healthy subject, no doubt the knowledge of such facts may not be important, for an obstructed artery soon has a clot formed within it, and the pressure of the blood on its end becomes materially lessened; but cases occur every now and then where, from constitutional causes, this clotting of the blood is delayed for many days, and, for example, forcible pulsation may be seen quite up to the ligature round the femoral artery after amputation through the thigh. But, excluding these cases—important as they are—the great strength of the catgut suggests that it may be employed for the ligature of piles, or of the pedicles of ovarian and other tumours, and have a value here second only to that of its application to single vessels. Is, then, its strength so enduring that it will resist any tendency to swelling of the constricted part when reaction ensues? We doubt not that evidence will soon be forthcoming on this head, but it is important to have the facts elicited by experiment in the laboratory before it is verified in the living subject, and it would seem that we could acquire sufficient evidence very readily. Mr. Lister's case was so strong that he could afford to acknowledge generously Mr. Barwell's effort to supply a reliable animal ligature; although Mr. Lister claimed that the catgut prepared on his new plan answered all purposes, he did not point out that Mr. Barwell's ligatures were any less efficacious or reliable, or hint that Mr. Barwell had not obtained a thread considerably superior to the catgut hitherto generally used.

On some of the minor and subsidiary issues raised by Mr. Lister, more divergence of opinion may be held than on the subject of the ligature. In particular, we would refer to his remarks on the presence and influence of micrococci in the ligatures he used in a case of thyrotomy. He appears to take it for granted that the mischief set up in that case was due to the action of the micrococci found in the interstices of the ligatures. But yet we are assured that these same organisms may occur in cases treated by Listerism and no mischief ensue. If so, there must at least be some other element in the former case, and Mr. Lister's remarks on this head are at any rate inconclusive.

◆

It has been proposed to employ rabbits for the purpose of testing the nature of supposed cases of rabies, on account of the readiness with which the disease can be transmitted to these animals. M. Raynaud lately communicated to the Académie de Médecine an account of some experiments by M. Lannelongue and himself on this subject. On Dec. 8th a child was admitted into the Hôpital Ste. Eugénie who had been bitten on Nov. 11th. After twenty-six days' incubation the child was seized with dyspnœa, which was followed by intense delirium, and the patient died on the fourth day. Three series of inoculation experiments were made. Four rabbits were inoculated with the saliva before the child's death. Of these three died rapidly; the fourth recovered after a period of considerable indisposition. Two rabbits inoculated with the blood recovered—a fact which is regarded as corroborating the opinion that the disease is transmitted by the saliva rather than by the blood. After the child's death a second series of experiments were made. Rabbits inoculated with the mucus from the bronchial tubes died. Juice from the salivary glands yielded a doubtful result, only one of the rabbits inoculated having died. At the post-mortem examination of the child it was found that the glands of the neck on the side of the face which had been bitten were much swollen. A scraping from one of these glands inoculated into two rabbits killed one of them. The roots of the two fifth nerves placed beneath the skin of a rabbit killed it at the end of three days, and hence it is assumed that the virus is abundant in the nervous system. In a third series of experiments inoculation was practised from a dead to a living rabbit, and it was found that death occurred even when the blood was employed. Of thirty-eight inoculations twenty-six were fatal. The average interval between the inoculation and the death was about forty-five hours, but only twenty-nine hours in the case of the inoculation from rabbit to rabbit. This short period of incubation, together with the fact that inoculation from the rabbit to the dog was without effect, raised considerable doubts as to whether it was indeed rabies of which the rabbits died. This doubt was expressed by many members of the Academy. M. COLIN pointed out that since the period of incubation in the herbivora is from twenty-eight to thirty days, it was much more probable that the animals died of septicæmia, since the saliva is a very putrescible liquid. This opinion was shared by M. DUJARDIN-BEAUMETZ. M. RAYNAUD admitted that the symptoms were not similar to those of ordinary rabies, but accepted a suggestion of M. BERGERON that the difference in the characters of the disease was probably the result of a difference in the dose. M. PASTEUR stated that he also had inoculated some rabbits from the same patient, taking a little mucus from the mouth four hours after death. The animals died thirty-six hours after the inoculation. With the saliva of these rabbits others were inoculated, and these also died. In the first series there was a swelling of the lymphatic glands, and both the glands and the trachea contained numerous hæmorrhages. In the blood of the rabbits taken immediately after death, a microscopical organism was found altogether peculiar. It had the form of a small rod, slightly constricted in the middle, in length about the 1000th part of a millimetre, or even less, and it was surrounded by the pale halo which may be seen around most microscopic organisms when they are placed in a certain focus. If these were placed in a cultivation liquid, as, for instance, in a decoction of veal, they rapidly multiplied, and always maintained the same form, but better defined. Sometimes the organisms were found arranged in 8-shaped chaplets. In cultivation the areola did not show itself. When the liquid in which they were growing was left to stand, the figure of 8-shaped arrangement disappeared, and only minute spherical points remained. This organism was without doubt the cause of the illness and death of the inoculated rabbits, for others inoculated with the organisms, after their artificial cultivation, died with just the same symptoms. Is the disease, thus inoculated, rabies? M. PASTEUR would not affirm this. It was certain that the saliva came from a child who suffered from rabies, but although M. GALTIER had shown that the period of incubation in the rabbit is comparatively short (eighteen days), the practical absence of incubation in these cases was a difficulty in accepting the conclusion that the disease was rabies. Of one thing M. PASTEUR was sure, that it was not septicæmia. The organism was not the same, and the symptoms were not the same. In his experience the disease was a new one. Guinea-pigs inoculated with it did not suffer at all, although it is an animal closely allied to the rabbit. On the other hand, the disease was readily transmissible to the dog, which dies in three or four days, but presents no symptoms of rabies.

At the next meeting of the Academy M. PASTEUR returned to the subject, and insisted again on the negative result of the inoculations on guinea-pigs as proof that the disease communicated to the rabbits was not septicæmia. He showed six guinea-pigs inoculated with considerable quantities of the new organism, obtained by artificial cultivation, and all the animals were in perfect health. On the other hand, a rabbit inoculated with the same material died in a few hours. In a series of comparative experiments M. PASTEUR inoculated some guinea-pigs with germs of the vibrios of septicæmia, collected in 1877, and carefully preserved in a tube; all died rapidly, with the characteristic symptoms of septicæmia. From these facts he considered the conclusion justified that the inoculation of the rabbits with the saliva of the hydrophobic child has given rise to a virulent disease, which is absolutely new, and which is characterised by a special organism.

It is to be hoped that the investigations initiated by M. PASTEUR will be prosecuted further, for the facts he describes are of extreme interest and importance, although it would be premature to affirm that he has discovered the organism of rabies.

At the same meeting some experiments by M. GALTIER of Lyons were communicated. In one series of observations the various salivary and buccal secretions of rabid animals were inoculated, with a view of ascertaining which of these secretions were virulent. The only evidence of virulence was obtained from the lingual glands, and from those of the mucous membrane of the mouth and pharynx. In a second series of experiments he found that the virus remains active for a certain time in the dead body, and even preserves its virulence after mixture with water, for one to three days. He obtained what he regarded as rabies in the guinea-pig with inoculation of the saliva collected ten days before, and preserved between two plates of glass. By cultivating the saliva of a rabid dog in the saliva of healthy animals he also obtained an organism which had the form of rods and chaplets. But, contrary to the results obtained by M. PASTEUR with his organism, which was cultivated in an indifferent liquid, M. GALTIER found that guinea-pigs inoculated with this saliva died in from eight to twenty-two days. Other guinea-pigs inoculated with the saliva of the first, died in from the fourth to the fifth day. By treating different mucous membranes with the saliva of rabid animals, M. GALTIER believes that he has conferred on animals an immunity to rabies. He has succeeded in inoculating rabies, from the dog, in the case of rabbits, guinea-pigs, sheep, and hares. He has not succeeded in communicating the disease to fowls. On the other hand, he found that the subcutaneous injection of the saliva of a rabid dog was capable of producing local inflammation and septicæmia, which caused death in from four to eight days. The injection beneath the skin of sheep of the juice obtained by squeezing the cerebral substance of rabid dogs, caused death in a single day. The disease did not appear to be rabies, for the saliva of the sheep did not communicate the disease to rabbits.

These experimental results are not altogether easy to interpret. It is possible that the facts discovered by M. PASTEUR may furnish a key to their significance. However this may be, the experiments are full of promise of important additions to our knowledge of the pathological relations of this terrible disease.

◆

THE Select Committee for investigating the working of the Medical Act and the merits of the several propositions for its amendment will be revived. Meanwhile the General Medical Council is sitting. It is announced that the chief business of the Council has reference to the Dental Register, though we can see nothing in the questions raised at the time of our going to press that could not have waited till the ordinary meeting of the Council. The time chosen for this session is unusual, and, occurring so closely on the death of the lamented chairman of its Business Committee, inopportune. It will be a melancholy waste of time and money if the Council should be tempted to repeat its oft-told opposition to schemes of medical reform. If this should be the case, is it too late, or is it really useless, to appeal to the members of the Council to consider whether the time has not come for the Council to accept with grace the judgment of the profession and to come to terms with it? It would be an enormous accession to the strength of the Council and to the force of its proceedings if it were somewhat reconstituted, and if it were to put itself right with the profession. There would be a feeling of respect for it and for its authority, the absence of which must be very painful to those members of the Council who spend much valuable time in fruitless discussions and weak recommendations. We can assure such members that the profession has no pleasure in disparaging what ought to be its most honoured public body. For ourselves, we should only be delighted to see the Council and the profession reconciled and helping each other to maintain the education of the profession, and the clear distinction contemplated by the Act of 1858 between qualified and unqualified practitioners. It is conceivable that the majority of the Council may foil the efforts of the profession, as the profession has repeatedly foiled the attempts of the Council at medical legislation, which in the judgment of the profession were imperfect. But what will be the good of that? The profession cannot recede, and the days are gone, or fast going, when a few corporations could long maintain a successful war against the body of educated and earnest men to which they owe all their importance. The time has come for an understanding to be arrived at, and we appeal with some hope to the Council to admit the fact. There must be eminent men in the Council, as there are outside of it, who see this. The Council will meet under the shadow of a great loss. Dr. ANDREW WOOD was a worshipper of the established order of things, but even he never sanctioned the exclusion of the profession from the Medical Council. He represented a College which in 1505 had "a seill of cause granted by the Towne Counsell of Edinburgh to the crafte of surgery and barbouris." One of its first rules was that no surgeon should take an apprentice who could not read and write. It was for a long time the only body in Scotland licensed to distil spirits! Bodies so old deserve reverence, but they need adaptation. Let the men who are younger than Dr. WOOD see the necessity, in the true spirit of conservatism, of adapting institutions which they wish to preserve to another century than that in which they were created. If such a spirit should now take possession of the Council, the meeting of 1881 may be a new departure for that body.

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF PHYSICIANS.

AT the meeting of the Fellows on the 27th ult., it was resolved to grant the use of the rooms of the College to the International Medical Congress from July 24th. Drs. G. Johnson, G. T. Fincham, J. E. Pollock, J. Andrew, and C. Chadwick were elected to serve on the Council. The annual report of the examiners for the College licence was read. It was resolved to admit to the privileges of the reading-room those medical officers of the Army, Navy, and Indian Services who have retired, on application to the Registrar in writing, accompanied by a recommendation from a Fellow or Member of the College, or from the head of the department to which the applicant belongs. A proposal from the Registrar to the effect that candidates for the licence be required to sign a declaration that they have not been rejected within three months, was negatived after some discussion, in which Dr. Pye-Smith, Dr. N. Moore, Dr. Quain, Sir W. Jenner, Dr. Pavy, and Dr. Fagge took part. A further proposition that the question of appointing auxiliary examiners be referred to the Council, and that meanwhile the President should be empowered to nominate such auxiliary examiners, if occasion arose, was carried.

FILARIAL PERIODICITY.

AT the last evening meeting of the Quekett Microscopical Club Dr. Cobbold communicated a fresh paper by Dr. Manson on the above subject, which is expected to appear in the next issue of their journal. The facts are remarkable. The paper opens with a careful consideration of the views of Dr. J. Mortimer-Granville, who has expressed the opinion that the phenomenon of filarial periodicity may be associated with sleep. This might occur, Dr. Granville thinks, owing either to the mechanical changes in the circulation when the body is in the recumbent posture, or to the different proportions of oxygen in the blood, or, again, to the relative alterations of blood and tissue.

Dr. Manson holds that his facts and observations prove (1) that the periodicity shown by the filaria embryos is by no means an exceptional or capricious phenomenon, and (2) that this periodicity is associated with the advent of night, not being in any way dependent on the sleeping state.

The second part of the paper records a series of observations on the blood, temperature, and pulse of two Chinese youths. Having ascertained that the young men were filarious, Dr. Manson proceeded to educate them to the performance of a systematic inquiry. Under his frequent supervision the young men not only readily recognised, but carefully counted, the embryos present in practically uniform quantities of blood taken from their own persons. The necessary self-vivisections were performed every three hours daily and nightly for a period of one month. At the same time they read accurately the teachings of the clinical thermometer, making also equally careful observations on the states of the pulse, the barometer, and the ordinary thermometer. The facts observed every three hours, daily and nightly, are recorded on a chart, in respect of which the author pledges himself as to its general accuracy, qualifying his statement only by the remark that "if there are any errors, they are few and unimportant."

One of the chief difficulties to be overcome had reference to the regulation of the quantity of blood to be examined. Whatever amount of actual bloodletting took place, the utilisation and accurate measurement of a single drop for each observation would have proved a cumbersome operation. The author, therefore, caused his pupil-patients to employ only "sufficient to form a thin workable film occupying a covering glass of 1½ in. by 1 in. in diameter." Although infinite pains were apparently taken to render the successive films equivalent to each other quantitatively, yet trifling differences of volume must inevitably have resulted. It would appear, however, that the substantial accuracy of the results remains unaffected.

Towards the close of his paper Dr. Manson refers to the results of his administration of quinine, nitrite of amyl, santonin, inhalations of turpentine, and quassia tincture sprays, but as regards any influence on the filariæ the results were negative.

A WINTER ON THE RIVIERA.

A CORRESPONDENT writes:—The Riviera has not escaped a reflex of the terrible winter, which, with unusual violence, has assailed the British islands. During the month of December, and while London was constantly enveloped in fog, the numerous patients who resort to these regions thought they had at last found real summer in mid-winter. At Hyères there were, in December, twenty-eight days of sunshine, and sunshine of a description unknown in England. There were but five days of wind, and one of rain. According to Dr. Biden's observations, the average maximum temperature for the month was 61·78° F., and the average minimum 44·9° F. The myrtle bloomed a second time; the may was beginning to show itself on the hedges, when January came with lowering clouds, gloom and cold winds. Seventeen days were given up to rain, and it often rained at night also. The rainfall from the 1st to the 25th amounted to four inches. According to Dr. E. Vidal's official reports for the French Meteorological Society, the average rainfall at Hyères during the last ten years is equal to 22 inches per annum. During nine days in January it was fine but cold, and there were but four days when it was at once fine and warm. It has frozen four times, and once with such severity as to kill many roses and flowers. This was on the 21st, the minimum reached by the thermometers in the more exposed portions of the town being 26·5° Fahr. On the 16th and 17th the thermometer fell to 28·5° and 28·75°. The maximum registered on these two days was, however, 37° and 40° Fahr. respectively, while the maximum on the coldest day was higher still—namely, 46·5°. In the more sheltered quarters of the town the thermometer never went lower than 29° F. On the 24th the thermometer just reached freezing point, and there was snow, but it melted on touching the ground. Thus, though six or seven degrees of frost is considered very severe at Hyères, the persistent gloom, rain, and cold winds were far more unpleasant to bear. The patients therefore protest that they have, after all, endured a severe winter, though there were but fifteen days in the month when the minimum temperature registered fell below 40° F. The fact is, that the houses and furniture are so unsuited to cold weather that a temperature which could be endured easily in England would occasion considerable suffering on the Riviera. Also the bursts of sunshine that will send the exposed thermometer up beyond 80°, when it falls to 35° F. at night, creates contrasts that are naturally difficult to bear. The complaints made at Hyères have been echoed throughout the Riviera, where rain and sleet, cold and wind, have been the universal torment. Each station has suffered, some a little more and some a little less, according to the amount of shelter that protects them, but none have escaped the inclemency of the winter.

THE CAMBRIDGE TRIPOS LIST.

IT is a fact of some significance that, in the list of wranglers of the recent mathematicnl tripos, among the first six there was not a single representative of the richly endowed scholastic establishments of Eton, Winchester, or Westminster, or of the old-established public schools like Rugby or Harrow. On the contrary, the first six wranglers received their primary education at institutions established at a comparatively recent date for the purpose of providing education at a cheaper rate than is attainable at the schools we have named. Thus we find the senior wrangler received his education at the Liverpool College; the second at Clifton College; the third at Owens College; the fourth at Windermere College; the fifth at Brighton College; and the sixth at King's College, London. If we turn to the classical tripos the same thing occurs, since we find a small school like Shrewsbury competing, and competing most successfully, against the heavily subsidised and specially trained scholars of Eton, Westminster, and Winchester. The success of Shrewsbury during the last forty years has been prodigious. At Cambridge, Shrewsbury men have repeatedly attained the distinction of senior classic, and quite recently this honour has been obtained by them three years in succession, whilst since 1848 no less than twenty-one Porson prizes at the same university have fallen to their share, and since 1868 they have carried off ten University (not college) Scholarships. Such success is, we believe, unparalleled, and appears marvellous when we consider that the school rarely exceeds 170 in number, and that there are no entrance scholarships to attract boys of special promise to it. This latter point brings the question of the advantage of entrance scholarships under notice on the present occasion. We are not, indeed, able to form an opinion, nor is it our province to attempt it, whether the comparative infrequency of scholars hailing from Eton, Westminster, or Winchester, being highly placed in the Cambridge class lists is due to any shortcomings in the educational system in force at these institutions. But the fact remains that lads selected by severe competition, at an early age, and then educated for the special purpose of attaining high University distinction in these highly endowed educational establishments, do not hold their own, as far as Cambridge is concerned, with institutions whose resources are more limited and whose scope is more general. Is it not probable that the premature forcing and severe training which a successful competitor for an Eton or Winchester scholarship has to undergo takes too much out of a lad at first, and places him in later years at a disadvantage with competitors who have matured more slowly, when the struggle at the University commences? This supposition is strengthened by the fact that a lad who has failed to obtain an entrance scholarship at Eton or Winchester has, not unfrequently, gone to some less pretentious school, and has succeeded in the tripos in turning the tables on his successful rivals of previous years.

DEATH BY DROWNING.

THE striking fluidity of the blood, often to be observed in the bodies of persons who have been drowned, has led MM. Brouardel and Vibert to make some experiments on the subject. They have found that when animals have been drowned slowly a large amount of water passes into the circulation, as is shown by counting the number of corpuscles in a given volume of the blood before and after immersion. They estimate that the water, in this case, amounts to not less than one-third of the total amount of liquid in the circulation. If death occurs rapidly, little or no water is absorbed. The water enters chiefly by the mucous membrane of the lungs, for ligature of the œsophagus makes very little difference to the quantity absorbed. Animals killed by the injection of water into the air-passages present a slighter amount of hydræmia than those killed by drowning. In the latter case the blood-corpuscles present only slight changes, and the chief difference to be detected is their lessened quantity. Small capillary hæmorrhages, however, are often to be found in the alveoli and parenchyma of the lungs, which explains the blood-stained foam which often flows from the nostrils and mouth of the drowned. Some of the epithelial cells of the lungs are altered, and present a granular and fatty appearance in consequence of the action of the water. The experiments will be found described in detail in the *Annales d'Hygiène Publique* for November.

DR. RICHARDSON'S LECTURE IN THE CHAPTER HOUSE OF ST. PAUL'S ON THE JEWISH SANITARY CODE.

ON the invitation of the Homiletical Society—a society of clergymen of the Church of England—Dr. Richardson delivered an address to the members on Tuesday last, in the Chapter House of St. Paul's Cathedral. The subject of the lecture was the Jewish Sanitary Code. The lecture opened with a description of the present Jewish population throughout the world. This was followed by a summary account of the privations and oppressions through which the Jews had passed since their last dispersion after their defeat by the Emperor Hadrian, A.D. 131–5, of the enthusiastic and brave Simeon, or, as he was also called, Barcochebas (son of a star). Next, the extraordinary vitality which the Jews had exhibited through all these troubles was described and their present remarkable vitality was fully detailed. The evidence thus adduced led up to the question, Why has the race shown such tenacity of vital power? The various hypotheses in answer to this question were related—(*a*) The supernatural; (*b*) facility for acclimatisation; (*c*) hereditary longevity; (*d*) superior physique; (*e*) sobriety. The lecturer, discussing these hypotheses, came to the conclusion that the phenomenon was the result of the observance that had been kept of certain cardinal points of the Mosaic sanitary code. Five of these observances were of special moment, and were sufficient to account for all that had been observed. They were the Passover cleansing; the seventh day's rest from physical and mental labour; the domestic care and the chastity of the Jewish women; the circumspection in regard to foods and drinks; and the succour which is ever given by the strong to the enfeebled. The meeting was rendered remarkable—we may even say memorable—by the circumstance that at the instance of Dr. Richardson, the Delegate Chief Rabbi, the Rev. Dr. Hermann Adler, was invited to be present. The learned Chief Rabbi not only came, but took part in the debate that followed the lecture, giving an admirable description of the definition which the great scholars amongst his people have rendered of the word 'leprosy."

NURSES FOR THE TRANSVAAL.

THE War Office has decided to suspend for the present the embarkation of the nurses from Netley, for service in the military hospitals in the Transvaal, a communication having been received from Sir George Colley that he has made arrangements for nurses in the colony for employment in the Base hospitals. Should the military operations against the Boers be extended, and the campaign resume larger dimensions, the Netley nurses would be telegraphed for.

MARCH FROM QUETTA TO KANDAHAR.

THE Commander-in-Chief in India has ordered the publication of the despatch from General Phayre, submitting a report of the march of the division under his command to Kandahar, as being "most interesting, and showing good work done under exceptionally difficult circumstances." This report unfortunately contains very little information respecting the health of the troops, making forced marches with the thermometer ranging as high as 120° to 130° Fahrenheit. "The heat during the day was sometimes very great, occasioning excessive thirst, which the brackish water of some places failed to quench, and, in addition, injured the health of a great part of the force." We are nowhere informed what was the effect of these untoward conditions upon the health of the men, nor what measures were taken to diminish it as far as possible, except that it is stated the men were carried "in bullock-carts from Sidi to Mach, a distance of fifty-five miles in three days." Our contemporary, the *Army and Navy Gazette*, asserts, however, "as a matter of fact we know that the men hardly ever got into the carts, and, moreover, were obliged in many places to shove them up steep inclines, over fords, and through deep sands. Indeed, far less work would have been entailed on the men had they had no carts at all, but good animal transport instead." Our contemporary accuses General Phayre of having in his report suppressed several unpleasant occurrences, and among others "that the 11th and 15th Foot, 15th Hussars, and Artillery lost quite sixty men from sunstroke and heat apoplexy before they reached Quetta." Among other matters omitted, we regret to find all allusion to the services of the medical department, which under such circumstances must have been very arduous. General Phayre has specially thanked by name twenty-six officers, military, political, commissariat, and transport, but has not thought it necessary to take any notice of the medical service. In this respect his conduct stands in striking contrast to that of Sir Frederick Roberts. We trust that the Commander-in-Chief and Governor-General will not allow this neglect on his part to operate against the medical officers receiving their due share of any credit which may attach to, or rewards which may be granted for, the arduous service performed on this occasion. We refrain from further comment upon General Phayre's conduct in this matter.

ROMAN ANATOMICO-PHYSIOLOGICAL INSTITUTE.

AT the opening of this institution, on the 16th ult., Prof. Tommasi-Crudeli enlarged on the material difficulties surmounted before the undertaking had become *un fait accompli*, and concluded his address by auguring from the good work achieved by unfavourably circumstanced Roman physiologists the better work they would put forth under more propitious auspices. It was in no completely equipped laboratory, but in the narrow cells of the Convent of S. Antonino, that Francis Boll in 1873 began to train his little band of physiologists and to make those discoveries which have once more drawn the eyes of *savans* to Rome. Already labouring under the malady to which he prematurely succumbed, Boll gave his pupils the example of a rare assiduity, and with his clear demonstration of the fact that the retina has a colour of its own (*rosso retinico*) he set the seal of science on his humble school. This discovery, preceded by interesting monographs by himself on the Electric Apparatus of the Torpedo, and by his pupil Colasanti on the Ovum, was followed by the elaborate paper of another pupil, the Marquis Stefano Capranica — "Studi Chimico-Fisiologici sulle Materie Coloranti della Retina" (Chemico-Physiological Studies on the Colouring Matters of the Retina). From these admirable beginnings Professor Tommasi-Crudeli anticipated the vigorous development the Roman medical school would ere long exhibit, and he resumed his seat with the announcement that the physiological course would be forthwith commenced by Professor Moleschott. This eminent teacher then delivered his inaugural discourse, the official publication of which will shortly place before the scientific world the author's latest views on human physiology in general, and on that of the nervous system in particular.

THE CLINICAL SOCIETY.

MR. LISTER's address, on taking the chair as President, occupied the whole of the meeting on Jan. 28th. On the conclusion of the address a vote of thanks to Mr. Lister was moved by Mr. Hutchinson, seconded by Mr. Heath, and carried by acclamation. Mr. Barker showed a case of Elephantiasis of the Hand and Forearm; Dr. Crocker, one of Melasma; Mr. Gould, of Dislocation of the Head of the Radius forwards, of fifteen years' standing; and Dr. Sturge, one of Motor Ataxy with exaggerated Tendon-reflex.

THE DISTRIBUTION OF THE RED BLOOD-CORPUSCLES.

S. D. KOSTJURIN has shown, in the *Petersburger Med. Wochenscrift*, that the proportion of blood-corpuscles in the serum varies considerably in different parts of the body, and in the same part under different conditions of the circulation. His observations were made with Malassez's numerator on the blood of healthy and diseased men and also in animals. He found that the red blood-corpuscles are considerably more numerous in the capillaries of the skin of the supra-clavicular region than in the skin of the little toe, and that this difference becomes more marked when the rapidity of the heart's action is increased. In healthy men the extremes observed were 274,000 and 1,037,600 in a cubic millimetre of blood; and in patients, especially those suffering from fever or valvular disease of the heart, the numbers varied between 621,300 and 1,847,000 in the cubic millimetre. Observations on dogs showed that if the rapidity of the blood-stream be lessened by cold, or by ligature of the supplying artery, the relative number of corpuscles is markedly lessened.

THE ARMY MEDICAL SCHOOL, NETLEY.

THE winter session of the Army Medical School of the Royal Victoria Hospital terminates on Monday next, when the Secretary of State for War, the Right Hon. Hugh Childers, M.P., is expected to visit Netley for the purpose of closing the session and presenting the Herbert and other prizes to the medical officers who have been awarded them at the examination just concluded. Owing to the large batch of probationers for the Army Medical Department, as well as the candidates for the Royal Navy and the Indian Medical Service, the class this session has been unusually numerous, and has caused a considerable strain on the accommodation of the school and hospital.

EXAMINATION STATISTICS OF THE COLLEGE OF SURGEONS.

THE following analysis of the last pass examination for the diploma of membership of the Royal College of Surgeons of England, which was brought to a close on the 26th ult., will be read with interest. There were 164 candidates—viz., 130 London students, 22 from the provinces, and 12 both metropolitan and provincial. Of this number 59, having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their professional studies for six months, and 10 gentlemen having passed in surgery, will be admitted members of the College when qualified in medicine. The rejections per night varied from 3 to 16. At the corresponding period last year there were 127 candidates, of which number 48 were rejected and 7 approved in surgery. The following were the recognised medical licences passed by some of the candidates, who, of course, were not required to undergo an examination in medicine again—viz., M.B. Lond., 1; M.B. Cantab., 1; M.B. Dub., 1; L.R.C.P. Lond., 2; L.R.C.P. Edin., 3; L.K. & Q.C.P. Ireland, 1; and with the additional L.R.C.S., 1; M.D. Paris, 1; L.S.A. Lond., 23; and Apothecaries' Hall, Dublin, 1.

NAVAL MEDICAL SERVICE.

THE examination of candidates for this service will take place in the course of a few days. The Admiralty has not yet done more than offer the "vague generality of equalising the Service with that of the Army," but it withholds the Warrant by which alone its intentions can be gauged. There are too many recorded instances of bad faith towards this branch of the Service generally, and even to individual officers, to permit us to place implicit confidence even in Warrants; and we would be pleased to find the coming examination afford evidence that the juniors of the profession are not to be easily induced to enter the portals where "Cave canem" should be affixed to the threshold.

OUR Birkenhead correspondent writes:—The fund now being raised for a new Children's Hospital is also being liberally supported. Mr. Stickell, the donor of the £250 to the Borough Hospital, has given an equal sum to the Children's Hospital; and at a bazaar lately held at Christchurch about £500 was gathered for the new building.—On Wednesday, Feb. 2nd, an interesting ceremony took place at the stipendiary magistrate's court. The Order of St. John of Jerusalem having kindly granted their bronze medal to James McGowen, Inspector of Roads, for an act of bravery in rescuing the lives of two men from a sewer in Birkenhead in October last, the medal was presented by his worship the Mayor, many of the principal inhabitants of the borough being present on the occasion.

ANOTHER illustration of the peculiar dangers to which medical men are exposed in the practice of their profession is afforded by the lamented death of Dr. Ferdinand Jencken of Kingstown. It appears that on Jan. 1st Dr. Jencken opened an abscess in the arm of a poor woman, having on his thumb at the time of operating a cut or abrasion so slight as to have been entirely overlooked. The hand and arm, however, soon afterwards became violently inflamed, symptoms of pyæmia rapidly supervened, and death closed the scene.

THE question of bursaries in the Aberdeen University, which was remitted to the Endowed Institutions and Educational Committee, has terminated by the Committee resolving to abide by the instructions of the Town Council, which embodied the recommendation that the tenure of the bursaries should be three years, but that no appeal should be made to the Home Secretary to increase them either in number or amount.

NO fewer than 100 persons are at present waiting their turn for admission into the Glasgow Royal Infirmary, and during the past year the daily average waiting at the Western was 68. This represents a very serious amount of unrelieved misery.

THE Queen has been plased to signify her intention of conferring the honour of knighthood upon James Risdon Bennett, M.D., President of the Royal College of Physicians of London.

HOSPITAL SUNDAY cannot be said to have been a success in Glasgow, church collections in aid of the infirmaries having greatly fallen off. In the city and its neighbourhood are about 400 churches; these gave to the Royal Infirmary last year only £873—that is, about 44*s.* each. This, of course, is very much less than it should be.

A MEMORIAL to the late Surgeon Thomas Power, R.N. who died at the Royal Hospital, Haslar, whilst on the staff there, Nov. 2nd, 1879, has been erected in the Naval Cemetery, Haslar, Gosport, by subscription amongst his brother officers and shipmates. The memorial is a Latin Cross in Portland stone, over six feet in height.

The Irish Medical Directory for 1881 contains new matter of interest and utility—e. g., an Index to Acts of Parliament having reference to Irish Medical or Sanitary Affairs, and a reprint, verbatim or in abstract, of the statutes specially affecting the medical profession in Ireland.

THE GENERAL MEDICAL COUNCIL.

A SPECIAL Session of the Medical Council was held on Thursday, for the purpose of considering questions arising under the Dentists Act.

The PRESIDENT, in opening the proceedings, said: I cannot but regret that it has been my duty to summon the Council at this inclement season, but it is for a special purpose of business connected with the Dentists Act; and it is to be noted that this is the first time that any such meeting has ever been specially summoned to discharge this new duty. The reason for our meeting now depends upon the fact that a question has been raised as to the accuracy of the Dentists' Register in over 500 cases; and it would seem improper to delay to a later period of the year, when the Council would meet for its ordinary business, the publication of the new volume of the Dentists' Register for 1881 in a corrected form. It will be in the memory of the Council that on July 15th, 1880, memorials from the Association of Surgeons Practising Dental Surgery, from the British Dental Association, and a letter from the honorary secretary of the British Dental Association, stating the grounds on which it was considered that a large number of persons ought to have their names erased from the Dentists' Register, were referred to the Medical Committee established under the Dentists Act by the General Medical Council, in order that they might ascertain the facts of those several cases named in such memorials and letter. At meetings of the Dental Committee held since that period, after prolonged deliberations with the solicitor to the Council, reports have been drawn up which will now be presented to you. The Council is now called upon to decide whether upon the facts stated in these reports all or any of the persons whose cases are reported upon should or should not be erased from the Dentists' Register; and one person whose case the Council has to decide is summoned to appear this day at four o'clock before you. It is not my intention to bring before the Council any business other than that for which it is my duty thus to summon you. There is one subject, however, connected with the business itself which I must in conclusion name, and that is the loss which this Council has sustained by the recent death of Dr. Andrew Wood, made the more grievous because sudden and unexpected. I am well aware that it is generally highly inexpedient to make observations, even those of high personal regard, on any who have been taken away in whatever manner from this Council table. But I am sure that it would shock the whole feelings of the Council were I to attempt to conceal the sense which we all entertain of the loss of so faithful a public servant and so warm a personal friend. . . . .

On the motion of Sir William Gull a vote of condolence with Mrs. Wood and her family in their sudden and painful loss was agreed to.

The Council then proceeded to the consideration of the dental business, and having heard the report of the Dental Committee, and considered the cases with counsel's opinion thereon in regard to the Dentists Act (1879), resolved, on the motion of Dr. Humphry, "That all qualifications now appearing in the Dentists' Register, other than dental qualifications, be erased therefrom."

The Council further resolved—"That the report of the Dental Committee not having put the Council in possession of evidence to show that any of the registered dentists named in the corrected list of persons submitted by the hon. secretary of the British Dental Association, or of the registered dentists named in the letter of Dr. Jacob, were not at the time of their registration *bonâ fide* engaged in the practice of dentistry, the Council is therefore not prepared to order the removal of any such persons from the Dentists' Register."

Also, "That certain persons mentioned in the Dental Committee's report as having been actually though erroneously removed from the Register, at their own request should, on application, be restored to the Register without fee."

This concluded the business of the Special Session, a fuller report of which will appear in our next.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

THE MEDICAL INSPECTIONS UNDER THE LOCAL GOVERNMENT BOARD.

A PARLIAMENTARY return, moved for by Mr. Alexander Brown, has been published, showing in a tabular form, in order of years, all the local visitations which have been made by medical inspectors under the direction of the Local Government Board, from the date of the establishment of the Board in 1871 to Jan. 1st, 1880, with regard to prevalence of disease in particular places and to questions therewith connected, and defects in sanitary administration, and stating in successive columns in regard to each visitation the following particulars:—1. Names and population of the places of sanitary districts inspected. 2. Date of the visitation (or, when several visitations have been made, of the first or them), and name of the inspector. 3. On what ground of complaint or otherwise this visitation was ordered. 4. Précis of facts reported by the inspector with regard to the prevalence of disease, and to the existing defects of sanitary administration. 5. Reinspections (if any) which have since been made in the same areas with reference to the defects of sanitary administration, with the date of each reinspection and name of the inspector. 6. Précis of the information had by the Local Government Board up to Jan. 10th, 1880, as to the sanitary state of the places, and when given.

In spite of the repellant form of a tabular return of this class, there is much interesting matter in this document. It furnishes some (although very slight) indications of the important part these skilled medical inspections have had in promoting sanitary progress in England and Wales. But in glancing over the return regret is more than ever excited that the reports of the inspectors are only very partially accessible. These reports, if they had been made as easily attainable as were the reports of the engineering inspectors of the General Board of Health (reports which have still a great value in the localities to which they referred, and in the history of sanitary progress of England) could not have failed to exercise a more important educational effect upon the places to which they applied, and to the people at large, than they have been permitted to do, because they have not been procurable at the Parliamentary printers. The Local Government Board, as a rule, puts these reports into type, prints them, and then, strange to say, issues them as a rule only by grace!

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Kensington.—Dr. Orme Dudfield has republished his monthly reports and special reports for the year 1880 in a single volume, and added to them a summary of the vital statistics. The majority of these reports we had occasion to notice when they first appeared, and with respect to the collected reports we can add nothing to what we have had to say in regard to previous annual collections, namely, that they form an exceptionally useful and instructive comment on the progress of sanitary work, not merely in Kensington, but in the metropolis generally, throughout the year to which they apply. Dr. Dudfield has the art not simply of setting forth the particular facts relating to his own district, but of treating of the more general sanitary questions that arise relating to the metropolis, and illustrating their bearings from the experience of his own district, so as to throw the completest light upon them. In this way his collected reports become a running commentary upon the intimate sanitary administration of metropolitan districts of the highest value for present information and for future reference.

West Ham (*Urban*).—The report of the medical officer of health (Mr. Thomas Drake) consists merely of a brief statement of the mortality statistics of 1880 with comments on the deaths from the principal zymotic disorders. The annual death-rate from all causes is given at 19 per 1000 population as compared with 17·5 for 1879. Of the general sanitary condition and administration of this important metropolitan suburb nothing is said, except a reference to the effluvium from trade nuisances which do not appear to be suppressed to the extent they might be, and to the very partial carrying out of the Adulteration of Food Acts.

THE POPLAR INFECTIOUS-DISEASE HOSPITAL.

The Poplar District Board of Works have addressed a letter to the Metropolitan Asylums Board, setting forth in detail the advantages possessed by their hospital for the reception of small-pox cases, and stating that (contrary to the opinion expressed by a committee of the Asylums Board) it will accommodate sixty-nine patients and a sufficient staff of nurses and attendants. Dr. Bridges is in favour of the Asylums Board hiring the hospital, and, from some slight knowledge of the building we possess ourselves, we are at a loss to conceive, under the present exigencies of the Asylums Board, a reasonable ground for their refusal to hire it. Nevertheless, the Board holds to its refusal. Although we understand that the hospital was built without the special approval of the Local Government Board as to its construction and arrangement, the *site* was approved by that Board after the building was erected, and we can hardly conceive that Board opposing the site independently of the consideration of the fitness of the building upon it for its purpose; but obviously the technical objections of the Asylums Board to the building cannot be reasonably sustained in face of Dr. Bridges' approval.

CUTTING-OFF THE WATER-SUPPLY OF THE METROPOLIS.

The Vestry of St. Mary's, Newington, have printed and circulated certain extracts from a Report of their medical officer of health, Dr. Iliff, and correspondence relating thereto, respecting the cutting-off the water-supply of houses in their district by the Water Companies south of the Thames. The extracts and correspondence go to show the arbitrariness of the proceedings of these companies in exacting their strict legal rights from the owners and occupiers of house property, and their extreme indifference to depriving families of water, no other supply of this essential fluid being obtainable in the neighbourhood except from their mains. That companies should possess powers of this sort, without any reserve as far as the sanitary necessities of the people are concerned, is a scandal upon the Legislature, and furnishes one of the most cogent arguments for a change in the administration of the water-supply of the metropolis. This circular of the parish of St. Mary's, Newington, strengthens this position greatly, and it will be read with great interest by all who take concern in the subject.

A resolution passed at an "indignation" meeting, held recently at Homerton, to protest against any increase of accommodation being made for small-pox patients in the Asylums Board Hospital there, expresses "surprise and alarm" that twelve of the hospital officials should have come direct from the hospital to the meeting. This reminds us of an incident during the epidemic of 1871–72. An official of the Local Government Board attended a meeting of the vestry of St. Pancras. In the course of the meeting it became known that he had come direct from the Hampstead Hospital, then used for small-pox cases, to the vestry meeting. Whereupon a great outcry among the members of the vestry at the audacity and thoughtlessness of the official for possibly bringing the contagion of small-pox among them. To which the official quietly replied, when the hubbub ceased, that considering the *warmth* of his reception by the vestry, he thought that the members might be quite easy upon the score of infection, as it was well known that *heat* was the best disinfectant.

Mr. Alfred J. Bernays, the analyst for St. Saviour's district Board of Works, in his report for the Christmas quarter 1880, has to speak unfavourably of the specimens of milk submitted to him for analysis, and makes a suggestive comment upon the improvement apt to occur when the dealer finds that the specimens of the fluid he sells have been sent to the analyst. The following observations on cocoa are also suggestive: "I should be glad to be informed," says Mr. Bernays, "when cocoa ceases to be cocoa. What are we to say of cocoas containing only from 12 to 20 per cent. of cocoa? The public is paying very dear for the accommodation of admixing coarse sugar and flour! If it would receive advice, a slice of bread-and-butter, with a thin drink of genuine cocoa, would be both wholesomer and cheaper, than when thickened and sweetened; but even if it should prefer such cocoas, at what point is admixture to end?"

The medical officer of health for Paddington, Dr. James Stevenson, is dissatisfied with the measures which have been taken by the Canal Company to clean the bed of the Paddington Canal. The cleansing appears to have been very imperfect, and when the hot weather returns it is doubtful whether the nuisance experienced from the canal will show much diminution.

The Stepney Board of Guardians have rescinded a resolution to give extra remuneration to their relieving officers for their services in working up arrears of vaccination. On reconsideration of the resolution it appears to have been held that to pay the extra remuneration would be to reward, as it were, the previous neglect of vaccination, out of which the arrears had arisen.

Lord Edmond Fitzmaurice, Mr. Pell, and others have introduced a Bill into the House of Commons for the appointment of a Commission for the alteration of areas of Local Government in certain cases, and for the rearrangement of boundaries.

The medical officer of health for Dundee (Dr. Wallace), in his report for the four weeks ending the 1st January, 1881, reports seven cases of typhus, three of which were directly connected with a fatal case mentioned in the previous month's report.

The Shoreditch Board of Guardians, in view of the prevalence of small-pox in their district, have decided that for a month the inmates of the workhouse shall not have permission to visit their friends outside, nor receive visits from their friends unless in a case of dangerous illness.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

Under the influence of the fifteen days of exceptionally low temperature ending on the 26th ult., the recorded mortality showed a further increase last week. In twenty of the largest English towns, estimated to contain in the middle of this year a population exceeding seven and a half millions of persons, 5730 births and 4523 deaths were registered last week. The births exceeded by 547, and the deaths by no less than 1266, the average weekly numbers during 1880. The deaths showed a further increase of 324 upon those returned in recent weeks, and were equal to an annual rate of 31·0 per 1000, against 21·3, 23·6, and 28·8 in the three preceding weeks. During the past four weeks of the current quarter the death-rate in the twenty towns has averaged 26·2 per 1000, showing an excess of 0·6 upon the average rate in the corresponding period of the five years 1876-80. The annual death-rate averaged 26·2 in London during the four weeks ending last Saturday, and was equal to 26·8 in the nineteen provincial towns.

The deaths referred to the principal zymotic diseases in the twenty towns, which had been 383 and 390 in the two preceding weeks, declined to 373 last week, and included 108 from whooping-cough, 94 from scarlet fever, 54 from small-pox, 39 from fever (principally enteric), and 38 from measles.

The annual death-rate from the principal zymotic diseases averaged 2·5 per 1000 in the twenty towns, among which it ranged from 0·7 and 0·8 in Wolverhampton and Leicester, to 3·4 in Newcastle-upon-Tyne and 4·1 in Liverpool. Scarlet fever showed the largest proportional fatality in Oldham, Sunderland, and Sheffield, and whooping-cough in Leeds and Liverpool. The death-rate from fever (principally enteric) was again considerably below the average. The 11 deaths from diphtheria in the twenty towns included 8 in London. Of the 54 fatal cases of small-pox 52 occurred in London and one each in Plymouth and Birmingham; no death from this disease was recorded in any of the seventeen other large provincial towns. The number of small-pox patients under treatment in the Metropolitan Asylum Hospitals at Homerton, Stockwell, Fulham, and Deptford, which had steadily increased from 77 to 516 in the thirteen preceding weeks, further rose to 520 on Saturday last. The new cases of small-pox admitted to these hospitals, which had been 118 and 142 in the two preceding weeks, declined to 114 last week. The Highgate Small-pox Hospital contained 30 patients on Saturday last, against 26 and 27 in the two previous weeks.

The deaths referred to diseases of the respiratory organs in London, which had been 371 and 617 in the two preceding weeks, further rose, under the influence of the recent low temperature, to 702, and exceeded the corrected average number in the corresponding week of the last ten years by 249; 481 were referred to bronchitis and 120 to pneumonia. The annual death-rate from lung diseases (excluding phthisis) was equal to 9·9 per 1000 in London last week, while the rate from the same diseases was 19·5 in Liverpool.

In the twenty towns last week the causes of 117 deaths were not certified, either by a registered medical practitioner or by a coroner; these were equal to 2·6 per cent. of the total deaths. The proportion of uncertified deaths was equal to 1·8 per cent. in London, while it averaged 3·3 per cent. in the nineteen provincial towns. No uncertified deaths were registered last week in Portsmouth, Norwich, or Plymouth, while the largest proportions occurred in Oldham, Leeds, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

In eight of the largest Scotch towns, having an estimated population of rather more than a million and a quarter persons, the annual death-rate averaged 34·7 per 1000 last week, against 24·6 and 31·1 in the two preceding weeks; this rate exceeded by 3·6 per 1000 the average rate in the twenty large English towns. The rates in the eight Scotch towns ranged from 22·7 and 29·0 in Aberdeen and Dundee, to 39·3 and 48·7 in Glasgow and Perth. The deaths referred to the principal zymotic diseases in the eight towns, which had been 102 and 107 in the two previous weeks, further rose to 125 last week, and were equal to an annual rate of 4·9 per 1000, while in the twenty large English towns the rate from these diseases did not exceed 2·5. In the eight Scotch towns the zymotic death-rate last week ranged from 1·4 and 1·9 in Aberdeen and Perth, to 8·5 and 8·7 in Paisley and Leith. The fatal cases of scarlet fever in the eight towns, which had been 27 and 28 in the two preceding weeks, were 27 last week, of which 10 occurred in Glasgow and 11 in Edinburgh and Leith. The 34 deaths from whooping-cough showed a further increase upon recent weekly numbers, and included 22 in Glasgow and 7 in Dundee. The 25 deaths from "fever" also showed a considerable further increase; 14 were returned in Glasgow, 4 in Edinburgh, and 4 in Paisley. Six of the 7 fatal cases of measles occurred in Glasgow. The deaths referred to "fever," which had been 15 and 8 in the two previous weeks was 11 last week, of which 5 occurred in Glasgow, 4 in Edinburgh, and 2 in Greenock. The deaths attributed to acute diseases of the lungs (bronchitis, pneumonia, and pleurisy), in the eight Scotch towns were 348 last week, against 191 and 307 in the two previous weeks; those 348 deaths were equal to an annual rate of 13·8 per 1000 of the population in the eight Scotch towns; the death-rate from the same diseases in London did not exceed 8·5. The greatest fatality of lung diseases in the Scotch towns last week occurred in Glasgow, Paisley, and Perth.

HEALTH OF DUBLIN.

The rate of mortality in Dublin showed a further increase last week upon the excessive rates in recent weeks. No less than 303 deaths were registered within the city and suburbs, 11 more than those in the previous week. The annual rate of mortality per 1000 estimated to be living, which was equal to 31·8, 35·1, and 45·7 in the first three weeks of the year, further rose last week to 47·4. During the first four weeks of the current quarter the death-rate in the city averaged no less than 40 per 1000, against 25·5 in London and 25·2 in Edinburgh. To the principal zymotic diseases, 34 or 11 per cent., of the deaths in Dublin were referred last week, or 3 less than those in the previous week; they included 15 referred to fever, 6 to whooping-cough, 5 to scarlet fever, 4 to diarrhœa, 2 to small-pox, and one each to measles and diphtheria. The annual death-rate from these zymotic diseases was equal to 5·3 per 1000 in Dublin last week, while it did not exceed 2·9 in London and 4·9 in Edinburgh. The deaths referred to fever in Dublin, including typhus, enteric, and simple fever, which had been 8 and 17 in the two previous weeks, were 15 last week, and were equal to an annual rate more than eight times as large as the average rate from the same causes last week in the twenty large English towns. The fatal cases of scarlet fever and whooping-cough also showed a slight decline. The deaths of infants were less numerous than in the previous week, whereas those of elderly persons showed a marked further increase.

HEALTH MATTERS GENERALLY AT HOME AND ABROAD.

DISEASED PORK ON THE FRENCH MARKETS.

M. Leclerc, meat inspector, has found trichinæ in pork received at Lyons from New York. There were, in all, fifty cases of American pork, weighing about 13,000 kilogrammes —quite sufficient, therefore, to poison even so large a population as that of Lyons. This alarming discovery has revived, to some extent, the question of organising special means of supervising the pork, bacon, &c., sold as food to the public. At Crépy en Valois, in the department of the Oise, Dr. Jollivet observed an epidemic of trichinosis in 1879, and several cases ended fatally. Yet, in spite of these facts, it has become a sort of fashion to treat this malady as a disease from which the French consider themselves exempt. The French, it is said, are such good cooks that there is no danger of trichinosis. Such disasters are only likely to occur with a coarse-palated public that can tolerate undercooked pork, and smoked, but uncooked, ham. Unfortunately, trichinæ will survive exposure to 20°C. of cold, and requires 70° to 75°C. of heat to ensure their destruction. If the piece of pork put before the fire is large, the centre of the meat is often not exposed to this degree of heat in the process of cooking. Now, there are about 900 pork-butchers in Paris alone, who employ some 2500 assistant-butchers, and these sell annually to the population 23,000,000 kilogrammes of sausages, bacon, and, in fact, pork generally. Under these circumstances the question arises whether a special staff of microscopists should not be attached to the laboratory which the Prefect of the Seine has just organised for analytic purposes, who would undertake the systematic examination of the pork imported from America and Germany, and also, though this is perhaps not quite so necessary, the pork of French origin. Such measures might advantageously be supplemented by the exercise of some sort of control over the piggeries and the stabling in rural districts. If the laws of cleanliness and ventilation were more strictly observed in the housing of cattle we should perhaps hear less of diseased meat. In the meanwhile travellers who visit the smaller French provincial towns should be careful in selecting their meat, whether pork or otherwise. The carcasses that have been properly examined by the slaughter-house authorities are stamped in several places; the mark is like a large post-mark, circular, and black, and no butcher has the right to sell meat that is not approved in this manner. But the smuggling of meat into the smaller towns is sometimes practised to avoid local dues and local inspection, and it is very probable that such meat would be offered in preference to foreigners, who might be supposed not to know these rules. It would be well if imported foreign or American pork could be stamped in a similar manner by competent inspectors.

Spotted typhus is said to have made its appearance in several parts of Saxony, originating, it would appear, with itinerant Slovak wireworkers. Measures have been taken to check the spread of the disease.

The Russian Society of Public Health is actively engaged in endeavouring to promote the foundation of sanitary colonies for the treatment of children suffering from chronic diseases.

The last mail from St. Thomas reports the existence of small-pox in the island, necessitating the imposition of quarantine on all vessels from that port.

Battersea Cemetery has, from sanitary considerations, been closed for common interments.

THE SERVICES.

WAR OFFICE.—Brigade of Foot Guards: Surgeon-Major Arthur G. Elkington, Grenadier Guards, to be Brigade Surgeon.

MEDICAL DEPARTMENT.—Surgeon-Major David Chambers McFall, who has been granted retired pay, to have the honorary rank of Deputy Surgeon-General; Surgeon-Major Watkin Sandom Whylock, M.D., has been granted retired pay, with the honorary rank of Brigade-Surgeon; Surgeon-Major James Africanus Beale Horton, M.D., African Medical Service, has been granted retired pay; Surgeon George Ryan to be Surgeon-Major.

INDIA OFFICE.—The Queen has approved the resignation of Surgeon Henry Prescott Roberts, M.D., of the Bombay Army.

The health of the troops at Kandahar is still far from satisfactory. Fevers and dysentery are very prevalent, the 11th Regiment having a large number in hospital from these complaints. The drinking water and sanitary condition of the city are reported as very faulty.

Surgeon-Major William S. Fox, Madras Medical Service, has been appointed by the Governor of Madras Surgeon on his Personal Staff.

Surgeon W. S. Pratt, Army Medical Department, proceeded in medical charge of the 97th Regiment from Gibraltar to Natal in H.M.S. *Tamar*, and remains for duty in the Transvaal.

Dr. John Davidson, C.B., Inspector-General Royal Navy, and Honorary Physician to the Queen, whose death is announced as having occurred on Monday at his residence, Bosworth-lodge, Willesden-lane, in the 64th year of his age, served against the Borneo pirates in 1844, and was Deputy-Inspector of the Royal Naval Hospital at Therapia during the Crimean war. He was Inspector of Plymouth Naval Hospital from 1868 to 1873, and had been Honorary Physician to the Queen since 1874. He was nominated a Companion of the Order of the Bath (Military Division) in 1867.

ADMIRALTY. — The following appointments have been made: Surgeon W. F. Spencer, additional, to the *Duncan*; Surgeon J. D. Anderson, to the *Salamis*, vice Spencer; Surgeon E. A. Lucas, to the Portsmouth Division of Royal Marines, vice Anderson; Staff-Surgeon W. D. Isaac, to the *Northampton*, for service in the *Griffin* when commissioned; Staff-Surgeon George Bolster, to the *Penelope*, vice Pickford.

Correspondence.

"Audi alteram partem."

"SIR WILLIAM GULL AND DR. PAVY."

To the Editor of THE LANCET.

SIR,—Will you allow me space to afford information upon one or two points which have not been placed in quite their true light in your leader of last week on the case between Sir William Gull and myself.

It is a minor matter, it is true, but you speak of me as "declining to give a certificate of the cause of death, and thus necessitating an inquest." Such was not my position. The physician has nothing to do with giving certificates of death of patients dying in the hospital. This is done in the Superintendent's office, and it was Dr. Steele who initiated the inquest. I was simply a witness in the case, in the same manner as the house-physician, sister, nurses, and others; and, holding the relation I did to the patient, and being the recipient of an important statement from her regarding the bath, I felt it was my duty as a British subject to attend the inquest and give evidence. Moreover, Dr. Steele met me within the hospital shortly after the inquest had been decided upon, and said he presumed that I should attend, and spoke of serving me with a subpœna; but I stated that it was unnecessary, as it was my intention to be present.

You speak of the clinical report as being part of the case for the prosecution, and ground an argument accordingly. A tale remains to be told about this clinical report. It was, in fact, through Sir William Gull (for the defence) that the clinical report was brought forward. It had formed no part of the evidence at the inquest, and Mr. Poland (for the prosecution) was taken by surprise when Sir John Holker (for the accused) referred to it, and stopped the case until it was settled that it should be received in evidence. I had never seen this report, and therefore knew nothing of its contents until I read it in Court after the trial had commenced. Here is Sir William Gull's evidence under cross-examination by Mr. Poland in relation to the report:—

Q. You would hardly put up your judgment in the case against the judgment of the physician who attended the case from the commencement?—A. I should, in this case, certainly, and I will tell you the ground of it.

Q. You would in this case, you say?—A. Yes, I would in this case.

Q. Upon the student's report?—A. Yes, upon the student's report.

Q. Upon the student's report you would put your opinion against that of Dr. Pavy?—A. Yes; the physician governs the student's report.

Q. Who governs it?—A. The physician.

Q. But supposing he never saw it?—A. But his duty is to see it.

Q. Then you are assuming that it is the same as if it was made by the physician himself?—A. No, not so much as that; but I was a physician at Guy's for twenty years, and my clinical reports were my own reports.

Q. They were made by a student?—A. I beg your pardon; I always dictated the report myself.

Such is an extract from the printed transcript of the official short-hand notes of the Court. It is not for me to comment on the statements made, except with reference to their bearing upon my own position in the matter. My connexion with Guy's has extended to a period of close upon thirty-four years—that is, before Sir William Gull was upon the staff of the hospital. I have never known the clinical reports as otherwise than truly students' reports. We indeed look upon case-reporting as a valuable means of promoting the systematic investigation of disease by pupils, and the manner in which they acquit themselves in the performance of their reportership duty is taken into account in awarding the higher appointments. But how would this system stand if the physicians always dictated the reports themselves? As regards the report in question, the case for the defence rested upon its holding an accredited position before the Court. As a matter of fact, however, it was (as Sir William Gull when it was in his hands had the opportunity of seeing) a student's report. The document consists of a printed form, and there are columns headed on each page, "Report by the Clinical Clerk" and "Notes by the Physician or Registrar," and the report down to the time of the administration of the bath was wholly upon the space allotted to the student.

In this particular instance a curious circumstance chanced to occur further affecting the value of the report as regards the purpose for which it was drawn into use. On June 1st there was a change of clinical clerks, and four new ones ought to have come on duty in my wards. One out of the four, however, failed to make his appearance, and the cases in the beds allotted to him had thus for a time no reporter attached to them. The patient, Louisa Morgan, whose death led to the trial, was admitted on June 9th into one of these beds, and it was not until June 25th that a student came on duty in place of the absentee. He then made a report of Louisa Morgan's case from what particulars he could pick up from the patient and within the ward, but what was noted down under the dates previous to June 25th did not fall under his own observation, for he never saw the patient until the day last named. The two records of temperature entered were copied from the back of the prescription paper, upon which they had probably been inserted by the house-physician.

This was the basis upon which Sir William Gull's argument for the defence and charge against me rested. From the profound secrecy observed, no opportunity was afforded for the acting medical staff to give the information which would have placed the circumstances of the case in their true light. Until it was produced in Court nothing was known by us about the report being intended to be made use of as it was, and much less that Sir William Gull was to appear as a witness and take the action he did upon it. So little consideration did Sir William Gull show for the true interests of justice in a criminal case, and so lightly did he regard the charge he made against a fellow-physician and colleague, that he took no pains to obtain particulars from anyone—physician, registrar, or house-physician—in actual contact with the patient, to determine whether the view he had taken was well founded.

I am, Sir, your obedient servant,
Grosvenor-street, Feb. 1st, 1881. F. W. PAVY.

⁂ We are, of course, perfectly well aware that the honorary physician of a hospital does not himself sign a certificate of the "cause of deaths" for any patient dying in the hospital; but the case is *his*, and he "gives" the certificate, though the resident officer actually signs it. The responsibility of causing a death to be certified or withholding a certificate, and thereby necessitating an inquest, rests virtually, if not formally, with the physician in charge of the case, and we are glad to believe that Dr. Pavy would not, under any circumstance, have allowed this case to pass without judicial investigation. That was what we meant to point out, and to this view of the matter we adhere. As to the circumstances under which the clinical report was "put in" we have nothing to say. This does not affect the fact that when "put in" it was *evidence*.—ED. L.

"AGITATION WITHOUT LEGISLATION."

To the Editor of THE LANCET.

SIR,—In a leader in THE LANCET, January 22nd, you give an interpretation to certain lunacy statistics that is, I think, open to question. The article I refer to alleges a concealment of the insane, "a concealment forced on the friends of the insane by the fears excited by agitation," and proposes to "show that the practice of evading the miserable law that exists is widespread," and that "the seeming decrease of the total of private patients upon which the Commissioners in Lunacy are disposed to congratulate themselves and the public, may be accounted for by the measure to which the growing distrust of the public is driving the relatives of the mentally diseased." It says that "with that shortsightedness common to public officials, the Commissioners in Lunacy and their friends and supporters interpret the figures as indicative of a decrease or at least a diminished rate of increase in the number of occurring cases of insanity." It even says that "it cannot be endured that official apathy and the misconstruction placed on official figures by incompetent statisticians should," &c.

I should myself be inclined to include as "incompetent statisticians" both those who draw the conclusion that the article says the Commissioners in Lunacy and their friends do, and also those who draw such a conclusion as is done by the writer of the article.

The Commissioners in Lunacy might fairly be left to defend themselves, but in this matter I fail to find anywhere any statements of opinion by them in the sense attributed to them by the article in question, and as a rule the Commissioners satisfy themselves with giving the bare facts and rarely indulge in any comments, and have often very unjustly been criticised for not doing so. If the writer of the article has any other facts in support of his view he ought to produce them, since he says it is a public duty to do so.

I do not wish to discuss the alterations in the law that are advocated in the article referred to, which may be, and in some respects are probably very desirable, but to call attention to the fact that the statistics which he uses to support his argument admit of a very different interpretation, an interpretation that will account for probably all the decrease recorded in the official figures. These figures show a marked diminution in the number of private patients during the year 1879. The meaning of this is to be found in the fact that the number of private patients depends not on the production of cases of lunacy, and not on the view the public may take as to asylums, but is directly dependent on the wealth and prosperity of the country—in other words, on the paying power of the patients' friends.

The falling-off of private patients in 1879 is the direct result of the commercial depression that has lasted some years, and culminated in the agricultural distress that marked that year. A glance at the figures for the past twenty years shows clearly that a large increase accompanied and followed periods of prosperity, smaller increases or diminutions occurred at periods of depression. The number rose in 1864 and 1865 to 214 and 224, falling in 1866 and 1867 to 41, and decrease 15; then rose gradually till it reached 381 and 269 in 1872 and 1873, falling in 1874 to 98, and continued in the following years at 119, 88, 95, 86, and in 1879, decrease 158. The converse fact is referred to by the Commissioners in Lunacy in their last report as follows: "By far the larger proportion of the 'pauper' patients in asylums have been pauperised only by their insanity, the great majority of these cases having really occurred among the ordinary working population, of whom, previously to the attack of the malady, comparatively few were in the receipt of any kind of Poor-law relief." The probability is that if such an analysis could be made, the missing private patients, whilst in many cases probably kept at home, though not from the motive stated by THE LANCET, would in the majority of cases be found among the increase of paupers for the year; and it is not unworthy of remark in connexion with this view, that the aggregate increase of private and pauper patients is very nearly the same in 1879 as in 1878,—although the private patients increased 86 in the one year and diminished 158 in the other.

I am, Sir, your most obedient servant,
T. A. CHAPMAN, M.D.
Hereford County and City Asylum, Jan. 25th, 1881.

"WOOLSORTERS' DISEASE."

To the Editor of THE LANCET.

SIR,—Being specially engaged, in conjunction with some of my professional brethren, in investigating the nature, &c., of "woolsorters' disease," certain portions of Dr. Greenfield's very interesting lectures have attracted my attention and aroused my curiosity. Might I be permitted most respectfully to ask Professor Greenfield to state, through your columns, the precise data upon which the identity of so-called "woolsorters' disease" and anthrax has been *conclusively established?*

It would also greatly facilitate our investigations in this neighbourhood if the Professor would tell us what are the diagnostic characters of the organisms he so frequently designates "typical bacilli," and of what they are "typical?" Might I also ask what are the essential differences between the so-called bacillus anthracis and the ordinary bacillus of putrefaction?

If the Professor will kindly answer the above queries, I feel sure that many gentlemen, including myself, will feel really grateful to him for the information.

I am, Sir, yours obediently,
Bradford, Jan. 25th, 1881. EDWARD T. TIBBITS, M.D. Lond.

STATISTICS OF OVARIOTOMY.

To the Editor of THE LANCET.

SIR,—Mr. Thornton in his reply to my letter on Statistics of Ovariotomy, after indulging in a few sneers which are utterly beyond the question, implicitly acknowledges having taken, without my knowledge or consent, a series of my unpublished cases from the register of the Samaritan Free Hospital, and utilised them for an incomplete and *ex parte* statement of results. This was exactly the point I had wished to make clear, and I now leave the case, which in my experience and that of others is unprecedented, to the judgment of the profession.

I am, Sir, your obedient servant,
GEO. GRANVILLE BANTOCK.
Granville-place, Portman-square, Jan. 31st, 1881.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.

To the Editor of THE LANCET.

SIR,—Whether the above is a bogus qualification or not I am not in a position to say, but Mr. Berry is quite wrong when he hints that the M.D. Aberdeen might just as well be viewed in the same light.

I admit the M.D. Aberdeen is given by promotion, after the M.B. has been two years in practice; but then only on certain regulations being fulfilled. When I went in for the M.D., two years ago, I had to lodge with the Dean of the Faculty of Medicine a thesis, to be approved by the Faculty of Medicine; I had to go up to Aberdeen to be examined in Logic, and also in Greek, in the latter because I had not previously passed in it, as it is not a compulsory subject for the M.B., nor with any of the other examining bodies before whom I have appeared. I do not think I have any reason for considering it a bogus degree.

Believe me, Sir, yours truly,

Cardiff, Feb. 1st, 1881. FRED. EVANS, M.D. Aberd.

IRELAND.

(*From our own Correspondent.*)

ALTHOUGH it is usual for a candidate for the Vice-Presidency of the Royal College of Surgeons in Ireland at the close of the year to declare his intention of coming forward for election in the following June, up to the present time no name has been put forward for the office now held by Mr. Chaplin of Kildare. It is, however, believed that if Mr. John Kellock Barton, a senior Member of Council, surgeon to the Adelaide Hospital, and Lecturer on Surgery in the Carmichael School of Medicine, would stand for the Vice-Presidency, he would be returned unopposed.

At the annual meeting of the Cork Ophthalmic and Aural Hospital, held recently, it was shown that the total expenses for the past year amounted to £480, of which the intern patients contributed £227. It will thus be noticed that one-half of the total expenditure was obtained from the patients admitted to the wards, a fact sufficient to show that the work done at this institution is appreciated by those seeking admission, more especially as the charge for intern patients has of late been increased.

At the fourth annual meeting of the Dublin Branch of the British Medical Association, held last week, Dr. Robert McDonnell, the outgoing President, delivered an address more especially directed to the compulsory notification of infectious diseases, a subject which he trusted would ere long be so far brought into action in Dublin as to sensibly diminish the high death-rate for which that city is unhappily notorious. The President alluded to Mr. Gray's Bill, which proposes to throw on the medical attendant—if one be in attendance—the duty of informing the sanitary authority when any inmate of a building used for human habitation is attacked by small-pox, cholera, scarlatina, typhus, typhoid, puerperal, or relapsing fever, diphtheria, measles, or erysipelas, and observed that he would hesitate to support this clause, not on the ground of the committal of any breach of confidence by the medical attendant, but because he doubted if it was the best method of attaining the object in view. It was also open to doubt whether the proposal would work well, which requires that the medical attendant should give notice to the master of the house, and on such notice the householder shall be required to communicate with the sanitary authority. Both of these propositions oblige the medical attendant to take the initiative, but Dr. McDonnell was disposed to think that it would be a just as well as a wiser course to throw on the householder the initial step, and that it should be the duty of the latter to ascertain from the medical attendant whether the disease was infectious. The importance of the compulsory notification of infectious disease is denied by none, but the detail as to who is to be the party—the householder, or the medical attendant—to inform the sanitary authority as to the existence of a contagious disease in a household is the real practical difficulty. I know that the feeling among the profession in Dublin is much against the onus of taking the initiative in the matter, and I am certain that with the present feeling every loophole of escape will be seized upon to evade notification by the practitioner in attendance. There is little doubt that Mr. Gray's Bill must be materially changed before it will be received with any degree of favour. The payment also to the medical attendant of one shilling for each certificate cannot be considered as munificent. The entire subject is, however, one which may be regarded with very different feelings; and the proposal of Dr. McDonnell, that the question should be thoroughly investigated by a select committee of the House of Commons, is one deserving of consideration.

The annual meeting of the subscribers to the Belfast Hospital for Sick Children, Queen-street, was held in the Clarence-place Hall, last week, presided over by the Hon. R. O'Neill. Resolutions were adopted congratulating the Committee on their success in paying off the debt on the building fund, and thanking the Ladies' Committee for their constant attention to matters connected with the best interests of the hospital. A vote of thanks was also accorded to the medical staff.

The recent concert for the benefit of St. Mark's Ophthalmic Hospital, Dublin, has resulted in a sum of £66 12*s.* 4*d.* having been obtained for the funds of the institution. Dr. James Little has been appointed consulting physician to the hospital, in the vacancy caused by the decease of Dr. Alfred Hudson.

In consequence of the prevalence in certain parts of England of foot-and-mouth disease, the Lord-Lieutenant and Privy Council have published an order prohibiting the importation into or landing in Ireland of any animal from Great Britain. The order came into force on the 1st inst., and continues during the present month.

The annual meeting of the friends of the Dublin Hospital Sunday Fund was held last Monday, presided over by His Grace the Archbishop of Dublin. From the annual report of the Council I learn that, last year, collections were made in 229 places of worship, the total amount contributed being £4050 7*s.* 9*d.*, showing a decrease of £264 11*s.*, as compared with 1879. After payment of the ordinary expenses, a sum of £3870 was available for distribution; and the Committee of Distribution have decided to divide the sum of £3750 among the sixteen participating hospitals. A proposition of Lord Plunket, that the advantages of the fund should be extended to institutions for nursing the sick poor at their own homes, more particularly St. Patrick's Home for Nurses for the Sick Poor, in York-street, was put to the meeting, and negatived.

During the past year 802 patients were treated at the Newry Fever Hospital, of which number 200 were admitted into hospital, and the remainder treated as out-door patients. The sanitary state of the hospital has been good, and the attendance of patients exceeded that of any previous year since the hospital was first established.

It is rumoured that Dr. McDonnell, F.R.S., may probably succeed the late Dr. Hudson, as Crown representative on the General Medical Council.

PARIS.

(*From our own Correspondent.*)

THE Paris Court of Appeal was recently the scene of a most extraordinary exhibition, and one which is probably unique in the annals of medical jurisprudence. Unimportant as it was in itself, the case which called forth the evidence about to follow is worthy of record, as it gives a better idea of the progress of psychological science in France than all the *annales* and *revues* issued by all the professors in the country. It is from the *Union Médicale* that the extract is taken.

Last October a young man had been condemned to three months' imprisonment under the following circumstances:—"Deux agents des mœurs avaient surpris le prévenu dans un urinoir de la rue Sainte-Cécile. Didier, deposaient-ils, commettait, seul, un acte obscène, et ils l'avaient observé du dehors pendant près d'un quart d'heure." The accused replied, that the police had sworn falsely, and that he had no memory of anything of the kind. He appealed from the decision of the court, and begged the eminent alienist, Dr. Mottet, who had treated him at the Hôpital St. Antoine, to testify in his defence. Dr. Mottet, called upon to make a report, stated that Didier was the subject of a most curious nervous disease. In magnetic sleep he would get up in the night, sit at a table and write in the dark. . . . One day Dr. Mesnet required a compress for a patient. He did not ask for it, but was only thinking of doing so. Immediately Didier, who was looking on, went and fetched one, *having read the thought of the doctor.* An experiment was then devised. Dr. Mesnet put Didier to sleep, and told his house-physician to think of something. The latter looking round for some subject of thought, chanced to see a female patient holding an infant in her arms. Thinking of the woman and child, the house-physician placed himself in front of the sleeper and asked what he saw.

"I see a woman."—"What is she like? Young?"—"I cannot see."—"Why not?"—"She holds a child in her arms and the child hides her face."

Such is the written report of Dr. Mesnet. Before the magistrate who had the hearing of the appeal, Didier seemed to have no recollection whatever of the circumstance which led to his apprehension, remembering only that he had had two profuse nasal hæmorrhages in the evening, which had weakened him to such an extent that he could scarcely walk, and had been obliged to rest against several lamp-posts as he went along. Dr. Mottet, called into the witness-box, declared that the accused was subject to frequent crises of magnetic sleep, during which he lost all consciousness of the outer world. The doctor proposed to put him at once to sleep. The proposition being accepted by the court, the judges and counsel retired into one room, physician and patient being conducted into another. In a few seconds Didier was asleep, and Dr. Mottet returned to the Council Chamber, leaving two keepers at the other door. Then the magnetiser called, "Didier, get up, and come here." Immediately the door opened, and Didier, pushing aside both keepers and magistrates, walked straight up to the doctor. After Didier had been marched about to the satisfaction of all present, one of the counsellors asked whether he might remember in the magnetic state what had occurred on the evening of his arrest. Dr. Mottet repeating the question, ordered Didier to remember. The young man looked at him hesitatingly and beseechingly. The doctor insisted, and reiterated his command. "What did you do?" Here the patient took his handkerchief from his trousers' pocket and seemed to be dipping it as if in water. He then passed it over his face several times. Everything was explained. Didier had had severe nasal hæmorrhage, and not wishing to be seen with blood on his face, he had gone into the urinal in question, where there was a constant flow of water at a convenient height. The magistrates, however, were not fully convinced. Was not the man perhaps playing a clever part? Dr. Mesnet now took the place of his colleague, and ordered the young workman to sit down and rewrite a letter which he had sent him from prison three months before. Didier hesitated. "I cannot write," he said, feebly. "Why not?" "Because I am not in prison." "I will it. Write." Didier obeyed hesitatingly; and when he had finished, his letter was compared with the former one. They were found to be identical. As a crucial experiment, the doctor approached quietly and suddenly thrust a pin into Didier's neck; no external manifestation betrayed his feeling. The magistrates seem to have been much struck with this proof of the prisoner's innocence, and returning at once into Court the president acquitted him, on the score of mental irresponsibility.

The municipal authorities have done much lately in the interests of public health, and this is no doubt mainly due to the presence of a number of medical men in the Town Council. They have now taken another step in the right direction, and the public at large will shortly possess an efficient and gratuitous means of protection against food adulteration. A laboratory is to be attached to the Prefecture of Police for the examination of suspected substances, the qualitative analysis of which will be performed for nothing; applicants being told whether their samples are good, bad, or adulterated. A quantitive analysis, however, will be charged for, the fee varying from five to twenty francs, according to circumstances. When a sample is found to be adulterated, an inspector of the department will be sent to the delinquent's shop to seize another specimen, and if this turns out badly, proceedings will be taken by the administration.

M. Kœberlé, the well-known surgeon of Strasburg, related a case at the Academy of Medicine in which he had excised two yards of small intestine. The patient, a young woman, aged twenty-two, had been subject for some years to acute attacks of abdominal pain, and on two occasions there had been symptoms of obstruction, which had, however, been overcome by the use of enemata. Since that time (October, 1880) the pain had been most constant and severe, not remitting day or night, and at times so intense that it could scarcely be soothed by hypodermic injections of morphia. Gastrotomy was performed on Nov. 27th, 1880, and four narrowings were found in the bowel, one being only four millimetres in width. These strictures were distributed over two yards of the gut (2 metres ·05), which was excised between two ligatures at each extremity, the vessels of the mesentery being secured by twelve ligatures. The ligatures of the ends of the intestine were then tied together so as to place the gut in the most favourable position for enterotomy, which was performed on the third day. The parts beyond the ligatures came away between the twelfth and fifteenth days; and on the twentieth the first alvine evacuation occurred. Five days later a band of strapping sufficed to prevent food or gas passing through the wound, which had entirely healed in six weeks. The operation was not performed antiseptically, and the temperature never rose beyond 38° Centigrade. During convalescence, and from the third day, the patient was fed by the mouth, with solid and substantial food—bread, meat, and eggs—sufficient liquid being given for the purpose of digestion only, the thirst being assuaged by injections of water into the rectum, seventy such injections having been made in the twenty days. The young woman, who is now quite well, has no pain or digestive trouble of any kind.

THE INTERNATIONAL SANITARY CONFERENCE.

(*From a Correspondent.*)

THE International Sanitary Conference, which will meet at Washington on the 3rd of January, 1881, will form an important event in the history of sanitary progress in the United States. It is the first International Sanitary Conference in which the United States Government has ever taken part. This Conference is the outgrowth of that agitation of sanitary questions which followed the great yellow fever epidemic of 1878, and led to the organisation of the National Board of Health, under the Act of Congress of March 3rd, 1879. By a subsequent Act, passed June 2nd, 1879, it was made the duty of that Board "to obtain information of the sanitary condition of foreign ports and places from which infectious and contagious diseases are or may be imported into the United States." The Board of Health, however, found insuperable obstacles in its efforts to obtain accurate information of the health of certain ports from which the greatest danger was to be apprehended. The peculiar difficulties met could be overcome only by the mutual co-operation of all nationalities interested in the commerce of ports most frequently affected with contagious and infectious diseases. The National Board of Health therefore took early measures to secure an International Conference on these and kindred subjects, and had at once the hearty co-operation of the President and the Secretary of State. Congress passed a joint resolution as follows:—"That the President of the United States is hereby authorised to call an International Sanitary Conference, to meet at Washington, district of Columbia, to which the several Powers having jurisdiction of ports likely to be infected with yellow fever shall be invited to send delegates, properly authorised, for the purpose of securing an international system of notification as to the actual sanitary condition of ports and places under the jurisdiction of such Powers, and of vessels sailing therefrom."

The Secretary of State accordingly issued the following circular under date of July 30th, 1880, to the Ministers representing the United States at the capitals of the Maritime Powers of the world:—

"Sir,—I have to state for your information that in pursuance of a joint resolution of Congress, which was approved on the 14th of May last, the President has determined to call an international sanitary conference, to meet at Washington, and to invite to join in the proposed conference the several Powers having jurisdiction of ports likely to be infected with yellow fever or cholera, with the view of securing the adoption by the Powers in question of an international system of notification as to the actual sanitary condition of ports and places under the jurisdiction of such Powers and of vessels sailing therefrom. I enclose herewith a memorandum in which the circumstances which have induced this Government to ask those of other nations to join in the proposed international sanitary conference are set forth, and which concludes with a statement of the specific propositions which the President would desire to submit to the conference. In view of the urgent necessity which, according to the experience of this Government, exists for prompt action in reference to this matter, I have to instruct you to lose no time in calling the attention of the Government of —— to this subject, by transmitting for its information a copy of the memorandum above mentioned, and by asking it at the same time to take into consideration the expediency of holding a conference of the character proposed, and requesting it to communicate its views on the subject to this Government at as early a date as may be convenient. You may add that it is thought by the President that such delegates as may be appointed by the several Powers to attend the proposed conference should be authorised to conclude, if deemed expedient upon consultation, an international convention in relation to any proper subjects for international sanitary regulations to be proposed for the consideration of the Governments interested. In order that the proposed conference, if agreed to by the several foreign Governments interested in the subject, may be held at as early a period as practicable, the President deems it expedient to suggest the 1st day of January, 1881, as a suitable date for the assembling of the conference in the city of Washington. In the event, however, that the Government of —— should have occasion to prefer a different date for the meeting of the conference, this Government will be ready to reconsider the question with a view to an alteration in the date."

The responses have been very cordial, and representatives have been appointed as follows:—England and Germany will be represented by the English and German Consuls-General at New York; Canada, by Dr. Tache, Deputy Minister of Agriculture, who has arrived here from Ottawa; Belgium, Mr. George Neyt, Chargé d'Affaires and Councillor of the Belgium Legation in Washington; Brazil, by Councillor A. P. de Carvalho Borges, Envoy Extraordinary and Minister Plenipotentiary of the Brazilian Government; Turkey, by Gregoire Aristarchi Bey, the Turkish Minister; Japan, by the Japanese Minister, Jushie Yoshida; Italy, by Prince de Camporeale, Chargé d'Affaires of the Italian Legation; Sweden and Norway, by the Minister, Count Carl Lewenhaupt; France, by Mr. Max Outrey, the French Minister; Mexico, by Senor Don Manuel M. de Zamacona, who is to arrive this week; China, probably by the Assistant Minister, Mr. Yung Wing; Portugal, by Viscount das Nogueiras and a specialist; Spain, by Senor Don Felipe Mendez de Vigo and a specialist; Austria, by Count Bethlen; Chili, by Francisco S. Astaburnaga, the Chilian Minister; Russia, by Mr. Michel Bartholomei; the Netherlands, by Mr. Rudolph de Pestel, Minister Resident; and Denmark, by Mr. de Bille, Chargé d'Affaires.

On the part of the United States the President has appointed Dr. J. L. Cabell, President of the National Board of Health; Dr. T. J. Turner, U.S. Navy, and Secretary of the National Board of Health; and the Attorney-General.

New York, Jan. 1st, 1881.

MEDICAL NOTES IN PARLIAMENT.

In the House of Lords on Tuesday the question of the water-supply of the metropolis was brought forward by the Earl of Camperdown, who suggested that, considering the state of things in the Lower House, it might be expedient for the proposed Bill of the Home Secretary, for the creation of a metropolitan water trust, to be introduced in the first instance into their Lordships' House. The Earl of Dalhousie, on behalf of the Government, could not make a definite statement on the subject, but could assure the noble lord that the question was receiving due attention.

In the House of Commons on Thursday, Jan. 27th, petitions for redress in connexion with the East India Army Medical Department were presented from G. Coates Bell, T. Matthew, T. McGann, and A. K. Reed. A petition was presented from St. Mary's, Rotherhithe, for inquiry into the affairs of Guy's Hospital. The Burial and Registration Acts (Doubts Removal) Bill was considered in Committee and reported without amendment. The second reading of the Medical Appointments Qualifications Bill was deferred to Thursday, Feb. 3rd. The Universities (Scotland) Voting Bill was read a second time without discussion.

On Friday further petitions for inquiry into the East India Army Medical Department were presented from R. Mantell, D. B. Smith, G. Y. Hunter, and C. T. Eves. The following notices were given for Tuesday:—Dr. Farquharson, to ask the Secretary to the Admiralty whether the report of the Committee on the pay and position of naval medical officers will be circulated before the next examination of candidates for the medical service of the navy. Mr. P. A. Taylor, to ask the President of the Local Government Board whether it is true that he has given any sanction to a resolution lately brought before the Holborn Board of Guardians, under which relief would be refused to all paupers who had not been vaccinated. Mr. Chaplin, to ask the Secretary of State for the Home Department if his attention has been called to a case of horse-poisoning at Ruskington, in Lincolnshire, which was tried before the magistrates at Sleaford on Jan. 10th, when it was shown that two horses, the property of Mr. Grist of Ruskington, had been poisoned with arsenic by George Olive, the person in charge of them, and that one of them in consequence had died. Whether he is aware that it was stated in evidence that arsenic sufficient to poison fifty horses had been sold by Mr. Smith, chemist, at Sleaford, to George Olive, and that it was entered in the chemist's book "to be given to horses." And whether the Government will take steps to check the indiscriminate sale of poison by chemists for the purpose of being given to horses.

Weights and Measures.

On Thursday, in answer to a question by Mr. Barran, Mr. Chamberlain said the Board of Trade had no power to interfere with verification by local authorities of glass measures; but they were, with the assistance of the Pharmaceutical Society, and a number of local authorities, preparing suggestions as to the measure that should be permitted. The Weights and Measures Act of 1879 provides that measures stamped by the inspector of weights and measures shall be a legal measure throughout the United Kingdom, unless found to be false and unjust. There has recently been a conviction in a case in which the measure was stamped by the inspector, and the conviction was quashed on the ground that the possessor was not aware, when using it, that it was false or unjust.

Naval Medical Officers.

In reply to Dr. Farquharson, Mr. Trevelyan said the report of the Committee on the pay and position of naval medical officers would be presented to Parliament as soon as the correspondence with the Treasury on some minor points was terminated. The scheme had virtually been settled. Ever since 1854 it had been understood that the payment and position of naval medical officers ought to be one-seventh better than of military medical officers on account of the relative advantages of service. He intended to bring a scheme before the Committee on Estimates to improve the condition of the naval medical officers. The scheme with regard to pay, pension, and retirement would come in force on the 1st of April, and successful candidates at the next examination would, from the moment of entering the service, under a new regulation, receive full pay as surgeons.

In answer to Mr. P. A. Taylor, Mr. Dodson denied that vaccination was enforced at the Holborn Union as a condition of relief; at any rate, he had sanctioned no such regulation.

Bequests and Donations to Medical Charities. St. Mary's Hospital, Paddington, becomes entitled to 200 guineas by the will of Mr. C. S. Ball, late of Cambridge-terrace, Hyde-park. Mrs. Clayton, widow of the founder of the Clayton Hospital, Wakefield, and whose funeral took place on the 26th ult., has bequeathed £200 to that institution. Mrs. Herbert Williams has just sent £500 to the funds of the Dorset County Hospital in memory of her late husband. The Grocers' Company have given £100 to the City Dispensary.

Obituary.

ANDREW WOOD, M.D. EDIN., LL.D., D.C.L., &c.

THE report of few recent deaths has been received with so much pain and surprise as that of Dr. Andrew Wood. Not many months since he was in London, playing his prominent part in the proceedings of the General Medical Council, and to all appearance as full of vigour and manly pugnacity as ever, suggesting to his friends how uniform was the flow of his health and spirits. True, he was seventy years old, but he bore them lightly, and they seemed no more than fifty to other men; when all at once the bad news came upon his friends. Almost as with Robert Levett,

> "With no throbs of fiery pain,
> No cold gradations of decay,
> Death broke at once the vital chain,
> And freed his soul the nearest way."

Dr. Andrew Wood, whose father and grandfather were both medical men and Fellows of the Edinburgh College of Surgeons, was born in September, 1810. He laid the foundation of that sound classical knowledge which was afterwards to stand him in such good stead at the High School, in the Rector's class of which he held a high place. He studied medicine in Edinburgh and Dublin, and graduated in the University of Edinburgh in 1831, in his thesis treating "De Cataracta." From his earliest years he was a man of action, and took a leading part first in the debates of the Royal Medical Society, and soon after in the business of the Edinburgh College of Surgeons, of which he became a Fellow, not in the lazy way of admission by testimonial, but by the examination which was in force in those days.

It is one good thing for which at least we have to thank the Medical Act of 1858, that by abolishing territorial restrictions of diplomatising jurisdiction, and creating a Council in which all divisions of the kingdom are represented, members of the profession from all these divisions, of very diverse histories, nationalities, and schools, meet around a common table and exchange views and amenities which have greatly improved and broadened professional feeling. One of the most prominent illustrations of this advantage of the Medical Act was Andrew Wood, who came, very much through the Medical Council, to be as much known in London as in his own beloved Edinburgh. As a physician Dr. Andrew Wood was well known and much respected. Though we do not remember any great contributions to either pathology or therapeutics, he had large experience both in private practice and in connexion with public institutions. He was surgeon to Heriot's Hospital, the Trades Hospital, and the Merchant Maiden Hospital. It was at Heriot's Hospital that he made those experiments as to the prophylactic use of belladonna in scarlatina which are constantly quoted. He was Inspector of Anatomy for Scotland. He was held in abundant honour by those who had the best means of knowing him by association and co-operation. His own College—the Royal College of Surgeons of Edinburgh—elected him as President in 1855, and have paid him the great compliment of returning him, without dispute, to the General Council of Medical Education and Registration ever since the creation of the Council. At Cambridge last year he was one of a group of medical men who received the degree of LL.D., as at Oxford previously he had received that of D.C.L.

The cause of Dr. Andrew Wood's death was somewhat rare, and, more interesting still, as being the lesion of which another great Edinburgh physician (Dr. Abercrombie) died—rupture of the heart. One of the cusps of the aortic valve was corrugated, and had been so, probably, for years. In addition to this, there was extensive calcification of the coronary arteries. It is remarkable that he never presented symptoms of angina. The muscular substance of the heart was remarkably soft, and in many places there were patches of fatty degeneration. But the fatal lesion was rupture of the cardiac fibres in the left ventricle, close to the septum. The passage so made into the pericardium was a narrow one, and less than half a crow's quill in diameter, so that the fatal hæmorrhage which ensued was comparatively slow, and extended over some hours. Eight ounces of coagulated blood were found in the pericardium.

There were three great traits in Dr. Wood's character. He was conservative; he was classical; he was hearty and human. His conservatism only interests us as it affected the affairs of the medical profession, though in Scotland it was a power which secured him respect from the leaders of the Conservative party. In medical politics he was pugnaciously conservative. He defended the old corporations and all they did—their preliminary examinations and their professional ones; and he challenged their enemies to meet him in the gate. About the year 1870 he was led by the force of public opinion to acquiesce in legislation for a compulsory consolidation of the corporations; but he afterwards rejoiced at the failure of this attempt at legislation, and ever since had objected to any interference with the freedom of these bodies. The Medical Council, too, had in him its most dauntless and thoroughgoing defender. All it did was good. Its Recommendations and its Visitations scarcely admitted of improvement. To do him justice, however, he had none of the narrow feeling which makes the Council so much afraid of the profession, and he always heartily supported measures for direct representation of the profession. For years past he had found recreation and solace in the close study and translation of the classics, especially of Horace. But, as our readers know, he was as much at home in translating Schiller or Lessing as in translating his own favourite Horace. It is not necessary to maintain that these translations were not serious rivals to similar works, but they were very creditable acts in the life of a busy professional man, and constitute an example that cannot be too frequently held up for commendation.

With all his honours and his culture, he retained his great human characteristics, his patriotism, his friendships. He loved Burns as much as he loved Horace, and sang the songs of his native land as fitly as if he had never been south of the Tweed. He will be greatly missed in London as well as in Edinburgh. We scarcely see how the Medical Council will get on without him. His long experience of its business as Chairman of the Business Committee, his good nature, his frankness, his bold defence of the old and the traditional, will be all missed. We can scarcely think that the meeting would have been held so soon had his death been anticipated. We do not pretend to have always agreed with him. But there was no difficulty in differing from him, as we differed much. We will even admit that his death removes an obstacle to reform. But for all that we have lost a friend whom we should have preferred to fight.

JAMES MACKIE, L.R.C.S. EDIN., L.S.A. LOND.

HEIGHINGTON, near Darlington, has sustained a severe loss in the death of the oldest practitioner in the neighbourhood. Mr. Mackie was born in Glasgow, and came to Heighington in 1844, where he resided until his death. He held the union appointment for many years, and for the last seven years he had also been medical officer of health to the Rural part of the Darlington Union. He was an able practitioner, and highly respected by his professional brethren. Besides being well acquainted with his own duties, which he performed with zeal and ability, he was a genial and intellectual companion, well acquainted with literature, and a good classical scholar. A year ago Mr. Mackie had a severe attack of bronchitis, followed by dropsical symptoms, which caused his death on the 17th of January, in his seventy-second year. There was a large attendance of friends and patients at his funeral, notwithstanding the severity of the weather, and those in his own profession included Mr. J. Jobson, J.P.; Dr. Eastwood, J.P.; Drs. Smith and Clark; and Messrs. F. Wilson, Tweddle, Fielden, Manson, and Hardy. The remains of the deceased were interred in the churchyard of Heighington. Many of the mourners were deeply affected.

ERNEST CRAVEN LUNN, M.R.C.S., L.S.A.

WE briefly announced last week the sad death of Mr. Ernest Craven Lunn, M.R.C.S., L.S.A., youngest son of W. Lunn, M.D., of Hull, who was knocked down by a hansom and instantaneously killed, in the presence of the lady to whom he had been engaged some time, who also received a fractured tibia, on Jan. 25th ult. Mr. Lunn entered at St. Thomas's Hospital, Oct. 1875; passed his first

M.R.C.S. in Jan., and his first L.S.A. in Aug. 1878. In October of the same year he entered Aberdeen University; and in April, 1879, there passed his First Professional Examination with honours, his second University Examination being passed the following April, his final L.S.A., Aug. 1880, and his M.R.C.S. Lond. so recently as Jan. 20th, 1881, receiving his diploma only five days before his decease. As a student he held every appointment tenable by such at St. Thomas's Hospital, and obtained a certificate of honour for midwifery. He was dresser to Mr. Mason and Mr. McKellar, and clerk to Drs. Bristowe, Gervis, and Payne. Mr. Lunn was looked upon by all as a rising young man, and held in the greatest esteem by all who knew him.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON. — The following gentlemen were admitted Members of the College on Jan. 27th:—

Beale, Edwin Clifford, M.B. Camb., Langham-street.
Saunders, Chas. Edw., M.D. Aberd., Lower Seymour-street.
Willis, William, M.D. Edin., Stanhope-street.

APOTHECARIES' HALL. —The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on Jan. 27th:—

Burrows, Charles William Grimes, Chesterfield.
East, Frederick William, Clapton-square.
Green, Harry, Padstow, Cornwall.
Holroyd, John, Rushworth, Halifax.
Thurlow, John Howard, Boston, Massachusetts, U.S.

The following gentlemen also on the same day passed their Primary Professional Examination:—

Hy. William Faulkner, Charing-cross Hospital; Francis James Lea, University College; Frank Charles Osborn, St. Mary's Hospital; John Henry Williams, London Hospital.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the quarterly examination held in January the following gentlemen passed the First Professional Examination:—

M'Cormick, J. D., Thurles.
Wilson, James, Glasgow.

The following gentlemen, having passed the Final Examination, were admitted Licentiates of the Faculty:—

Farwell, A. A., M.D., Paisley.
Gabe, J. Bernard, Glasgow.
Macfarlane, N., Glasgow.
Nasmith, G. C., Glasgow.

Five candidates were remitted at the First and nine at the Second Examination.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW. — At the quarterly examination held in Glasgow in January the following gentlemen passed the First Professional Examination:—

Alvares, E. M., Bombay.
Foulston, E. J., Leeds.
Horn, R. J., Preston.

The following gentlemen, having passed the Second Professional Examination, were admitted Licentiates of both bodies:—

Cook, Edmund A., Glasgow.
Corkery, W. A., Bombay.
Cattermole, J. F., M.D., Canada.
Dutt, M. R., Madras.
Head, J. G., M.B., Canada.
Marchmont, F. G., Bombay.
Patchett, E. J., Glasgow.
Simpson, E. J., Bombay.

Three candidates were remitted at the First and seven at the Second Examination.

[The fourth name in our last published list of gentlemen who passed the College of Surgeons on the 24th ult. should have been as follows: "Gresswell, Dan Astley, Louth."]

THE annual dinner of the Hunterian Society will be held at the Albion Hotel, Aldersgate-street, on Saturday, Feb. 12th, at 6.30 P.M., John Couper, F.R.C.S., in the chair.

A SPECIAL appeal was made on Sunday last in the various churches and chapels in Doncaster on behalf of the infirmary of the town.

WILLIAM GRANT, M.B. Glas., C.M., of High Blantyre, has been placed on the Commission of the Peace for Lanarkshire.

AT the last meeting of the Sanitary Institute of Great Britain (B. W. Richardson, M.D., F.R.S., in the chair) eight Fellows were elected, among whom were the Bishop of Exeter, Sir Stafford Northcote, General Bartlett, and Colonel G. E. Waring (U. S. America). Two Members were also elected.

A MEDICAL student at Birmingham, last week, was found dead in his father's surgery. It would seem from the evidence adduced at the inquest that the fatal result was due to taking prussic acid, probably inadvertently.

THE Committee of the Chelmsford Dispensary and Infirmary have resolved on the purchase of a site and the erection thereon of a more commodious building than the present one. The subscriptions paid or promised for the purpose amount to £1667, but the sum of at least £4000 will be required.

THE GERMAN HOSPITAL.—The annual General Court of Governors of this charity was held on the 26th ult. at the Cannon-street Hotel, under the presidency of Baron H. Von Schroeder, the treasurer. The whole number of patients attended during the past year was 19,453. The receipts had been £9195 and the expenditure £8738.

HOSPITAL AND EDUCATIONAL REFORM.—On the 31st ult. a meeting of the Westminster Liberal Union was held at their offices, Regent-street, to consider the question of agreeing to a memorial to the Home Secretary on the reform of administration of London hospitals. After considerable discussion the memorial was adopted.

EDINBURGH EYE INFIRMARY. — At the annual meeting of the subscribers to this institution it was stated that the indoor patients for the past year numbered 11, outdoor patients 1070; it appeared from an abstract of the accounts that the income amounted to £104 and the payments to £83, the whole of the officers of the institution acting gratuitously.

AT the annual meeting of the friends and supporters of the Liverpool Infirmary for Children, held on the 26th ult., the Mayor threw out the suggestion that an appeal in aid of the funds of institutions such as that whose interests he was advocating might be made to the children of the towns and neighbourhoods where such charities existed. The attendances last year at the above named infirmary were stated to have amounted to 29,250.

THE inhabitants of Millbrook (Cornwall) and its vicinity have expressed their regard for, and their appreciation of the skill and kindness of Mr. E. J. Worth, M.R.C.S. Eng., by presenting him with a valuable testimonial in the shape of a silver salver with a smaller salver, tankard and two beakers. A roll of vellum, containing the names of the subscribers, to the number of 300, accompanied the gift.

THE annual meeting of the supporters of the Liverpool Royal Infirmary, Lock Hospital, and Lunatic Asylum was held on the 31st ult. The report read by the treasurer stated that the efficiency of the infirmary had been maintained. The financial position continued to be a source of anxious attention to the committee; the debt had been increased during the year by £753, and now stood at £3600. The total income of the year was £14,732, and the expenditure £14,576.

NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR. The annual meeting of the Governors was held at the offices, 12, Pall-mall, S.W., on the 2nd instant. In the absence of the President, Viscount Eversley, Sir Harry Verney, Bart., M.P., Vice-president, took the chair. The report presented recorded a continuance of the efficiency of the institution, and that an increased number of patients had been benefited by treatment at the hospital during the past year. The receipts for the year amounted to £7216 and the expenses to £7380. His Royal Highness Prince Leopold was elected President in succession to Viscount Eversley. The medical report was read by the Hon. Visiting Physician, Dr. Sinclair Coghill, and it stated that 598 patients had been treated at the hospital, the mortality being only 2·8 per cent.

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN. At the annual general meeting of the contributors to this hospital, held on Jan. 21st, it was stated that no fewer than 546 children had been treated within the wards, an increase of 114 over last year, while 6612 had been treated at the dispensary, being an increase of 1651 over the previous year. The mortality was unusually high, there having been 96 deaths; this was due chiefly to the widespread and virulent epidemic of scarlet fever which had been raging in some parts of the city during the past four months. The expenditure for the year had exceeded the income by nearly £1450.

Science Lectures at the Parkes Museum of Hygiene.—Professor Corfield lectured at this museum on Saturday upon the subject of "Water-supply and Filtration." The Professor referred at some length to the engineering feats of the ancient Romans, and described the aqueducts with which Rome and Lyons were supplied with water. Three of these aqueducts remained to the present day as the channels by which modern Rome is supplied with water, and were monuments to the engineering skill of those who constructed them, and Rome at the present time had one of the best water supplies of any city in the world. The properties of water were explained, and demonstrated by experiments. Though pure water should be colourless, tasteless, and free from particles in suspension, it did not follow that water which had all these properties was pure and fit for drinking purposes. The various sources of water-supply were spoken of, and filtration for purifying water on a large scale in reservoirs, and on a small scale for domestic purposes was explained. The lecture was listened to with much interest, and at the close a cordial vote of thanks was given to Professor Corfield. The proposer, as a working man, said these sanitary science lectures were highly appreciated, and he for one should henceforth pay greater attention to the sanitary arrangements of his house.

The London International Medical and Sanitary Exhibition, 1881.—Considerable progress has been made with the arrangements for this Exhibition, and since the publication of the first list of the guarantee fund several contributions have been received. In addition to the medical and sanitary sections, there will be a miscellaneous section, consisting of school furniture and other articles more or less connected with the general purpose of the Exhibition. Applications for space are to be sent in not later than Thursday, March 31st, 1881; but from India, the Colonies, and America applications will be received up to April 15th. Full particulars may be had on application to the Secretary, Mr. Mark H. Judge, Parkes Museum of Hygiene, Gower-street.

Royal Hospital for Women and Children.—The annual meeting of this hospital in the Waterloo-road, formerly known as the Royal Infirmary, was held on Tuesday last. The Lord Mayor presided, and commenting upon the satisfactory report presented, expressed his pleasure that so much good should have been effected at little cost, there having been in the year 378 in-patients, and 7859 out-patients; 26,872 visits had been paid to out-patients, and 1153 visits to sick children at their own homes. At the conclusion of the meeting warm thanks were given to the medical, nursing, and general staff.

A council meeting of the Metropolitan Hospital Sunday Fund, in the Mansion House, is announced for Monday next, Feb. 7th, at 3 o'clock, for the following purposes:—To elect officers, and the committees for general purposes, and for distribution for 1881; to consider the reference from the last annual general meeting, relative to surgcal aid and kindred societies; and for general business.

The West Ham Board of Guardians have raised the salary of Dr. Scoresby-Jackson, medical officer for Walthamstow, to £150 per annum.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning, at the latest*

Armstrong, J., M.B., L.R.C.S.Ed., has been reappointed Honorary Physician to the Liverpool Infirmary for Children.

Barnes, R., M.D., F.R.C.P., has been appointed Consulting Physician to the Royal Maternity Charity.

Barton, J. A., M.B., C.M., has been appointed Medical Officer for No. 6 (St. George's) District of the Barton Regis Union.

Cooper, J. N., L.K.Q.C.P.I., M.R.C.S.E., L.S.A.L., has been appointed Medical Superintendent of the Infirmary, St. George's-in-the-East.

Curtis, A., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Staines Urban Sanitary District.

Dinwoodie, W., M.D., C.M., has been appointed Medical Officer to the Third District of the Bellingham Union.

Evans, E., M.B., C.M., has been appointed Public Analyst for the County of Anglesey, vice Owen, resigned. £1 1s. per analysis.

Gilroy, J., L.F.P. & S., L.M., has been appointed Parochial Medical Officer and Vaccinator for the Parish of Middleborough, Dumfries-shire, vice G. R. Underwood, M.B., resigned.

Hayward, R. S., M.D., has been appointed Medical Officer and Public Vaccinator for the Tenth District of the Chelmsford Union, vice Betts, resigned.

Head, R. T., L.R.C.P.L., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Cherryhinton District of the Chesterton Union.

Jeffreys, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the New Industrial Schools, Ashgate-road, Chesterfield.

Langton, J., F.R.C.S.E., has been appointed Surgeon to St. Bartholomew's Hospital, vice Holden, resigned.

Lenihan, P. J., L.R.C.S.I., has been appointed Surgeon to Dawson-street Provident Dispensary, Manchester.

Lucas, H., M.R.C.S.E., L.S.A.L., has been reappointed Medical Officer of Health for the Godmanchester Urban Sanitary District.

Lucas, R., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer for the Fulborn District of the Chesterton Union.

Mair, A. H., M.B., C.M., has been appointed Medical Officer to the First District of the Woodstock Union.

Morris, F. H., M.D., M.R.C.S.E., has been appointed Medical Officer to the Earl's Barton District of the Wellingborough Union.

Norris, E. S., M.A., M.B., has been elected Honorary Visiting Surgeon to the Windsor Royal Infirmary, vice J. W. Gooch, M.R.C.S.E. resigned.

Outton, H. W., M.D., L.R.C.S.I., has been appointed Resident Surgeon and Apothecary to the Meath Hospital.

Peck, E. G., B.A., M.R.C.S.E., has been appointed House-Surgeon to St. George's Hospital, vice H. M. Sheild, appointed House-Surgeon to Addenbrooke's Hospital, Cambridge.

Pound, F. J., M.R.C.S.E., L.S.A.L., has been appointed House-Surgeon to the Royal Hants County Hospital, Winchester, vice Leedham Fuller, resigned.

Rawdon, H. G., M.D., L.R.C.P.Ed., M.R.C.S.E., has been reappointed Honorary Surgeon to the Liverpool Infirmary for Children.

Roper, G., M.D., M.R.C.P.L., M.R.C.S.E., has been appointed Consulting Physician to the Royal Maternity Charity.

Stewart, J., L.F.P.S., has been appointed Surgeon to the Forester's Society, Court Charity, Thornton, Bradford, vice James Murray Park.

Sykes, W., L.R.C.P.Ed., M.R.C.S.E., has been reappointed Medical Officer of Health for the Mexborough Urban Sanitary District.

Wotton, C., M.D., M.R.C.S.E., L.S.A.L., has been appointed Medical Officer to the King's Langley District of the Hemel Hempstead Union.

Births, Marriages, and Deaths.

BIRTHS.

Benton.—On the 29th ult., at Bennett-street, St. James's, the wife of Samuel Benton, L.R.C.P., M.R.C.S.E., of a son.

Bisdee.—On the 31st ult., at Hopewell House, Cleveden, Somerset, the wife of Alfred J. Bisdee, M.R.C.S.E., L.S.A.L., of a son (prematurely).

Gabe.—On the 27th ult., at the London Dispensary, Spitalfields, the wife of J. Rees Gabe, M.R.C.S.E. &c., of a daughter.

Gittins.—On the 27th ult., at St. John's, Horselydown, S.E., the wife of John Gittins, M.D., of a son.

Jones.—On the 19th ult., at Harrogate, the wife of A. O. Jones, M.D., of a daughter.

Meadows.—On the 26th ult., at Otley, Ipswich, the wife of G. F. W. Meadows, M.R.C.S.E., of a daughter.

Milson.—On the 29th ult., at Finchley-road, South Hampstead, the wife of R. Henry Milson, M.D., of a daughter.

Siccama.—On the 1st inst., at Portland, the wife of Fleet-Surgeon R. R. Siccama, H.M.S. *Warrior*, of a daughter.

Wallis.—On the 24th ult., at Priory-place, Doncaster, the wife of Ferdinand Wallis, M.R.C.S.E., of a son.

MARRIAGES.

Ellis—Newton.—On the 19th ult., at St. Mary's, Whittlesey, Joseph Watson Ellis, M.R.C.S.E., of Swavesey, to Laura Edwina, daughter of the late Edwin Newton, of Whittlesey, Cambridgeshire.

Tamplin—Ree.—On the 28th ult., at Holy Trinity Church, Brompton, Charles Harris Tamplin, M.R.C.S.E., of Ramsgate, second son of the late R. W. Tamplin, of Old Burlington-street, W., to Amy Constance, only daughter of Dr. Ree, formerly of Fulham.

Thew—Atkinson.—On the 26th ult., at St. Andrew's, Newcastle-on-Tyne, by the Rev. Bernard East, Edwin P. Thew, M.B., C.M., of Alnwick, son of the late Edward Thew, of Shortridge, Northumberland, to Helen, younger daughter of the late James Atkinson, of Framlington-place, Newcastle.

DEATHS.

Askwith.—At Huntley Lodge, Cheltenham, suddenly, Robert Askwith, M.D., aged 65.

Cobbett.—On the 25th ult., at Petworth, Torquay, Robert Newberry Cobbett, M.R.C.S.E., of Portobello, Edinburgh, and late of Albury, New South Wales, aged 50.

Dabbs.—On the 30th ult., at 11, Brunswick-terrace, New-road, Buckland, Hants, Fleet-Surgeon George Henry Dabbs, R.N., aged 79.

Davidson.—On the 31st ult., at Bosworth Lodge, Willesden-lane, John Davidson, M.D., C.B., Inspector-General R.N., Honorary Physician to the Queen, aged 63.

Holden.—On the 27th ult., John Fearne Holden, Medical Officer of Health for Hull, aged 50.

Izod.—On the 29th ult., Freeman Izod, M.R.C.S.E., of Fletcher House, Tottenham, aged 54.

Lunn.—On the 25th ult., Ernest Craven Lunn, M.R.C.S.E., L.S.A.L., youngest son of W. J. Lunn, M.D., of Hull, aged 24.

Morton.—On the 15th ult., in London, Surgeon-Major Edward Morton, of the Bombay Army.

Papineau.—On the 28th ult., at Milford House, Homerton, William Papineau, M.R.C.S.E., in his 63rd year.

N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, Feb. 7.

Royal London Ophthalmic Hospital, Moorfields. — Operations, 10½ a.m. each day, and at the same hour.

Royal Westminster Ophthalmic Hospital.—Operations, 1½ p.m. each day, and at the same hour.

Metropolitan Free Hospital.—Operations, 2 p.m.

Royal Orthopædic Hospital.—Operations, 2 p.m.

St. Mark's Hospital.—Operations, 2 p.m.; on Tuesday, 9 a.m.

Royal Institution.—5 p.m. General Monthly Meeting.

Royal College of Surgeons of England. — 4 p.m. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

Medical Society of London.—8½ p.m. Third Lettsomian Lecture: Sir Joseph Fayrer, "On Tropical Dysentery and Diarrhœa."

Tuesday, Feb. 8.

Guy's Hospital.—Operations, 1½ p.m., and on Friday at the same hour.

Westminster Hospital.—Operations, 2 p.m.

West London Hospital.—Operations, 3 p.m.

Royal Institution.—3 p.m. Professor Edward A. Schäfer, "On the Blood."

Royal Medical and Chirurgical Society.—8 p.m. Ballot.—8.30 p.m. Mr. Frederick Treves, "On a Case illustrating the condition of large Arteries after Ligature under Antiseptic and non-Antiseptic Measures."—Mr. Jeremiah M'Carthy, "On a Case of Aneurism of Axillary Artery, probably ruptured; treated by Antiseptic Ligature of third part of Subclavian Artery."

Wednesday, Feb. 9.

National Orthopædic Hospital.—Operations, 10 a.m.

Middlesex Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital. — Operations, 1½ p.m., and on Saturday at the same hour.

St. Thomas's Hospital. — Operations, 1½ p.m., and on Saturday at the same hour.

St. Mary's Hospital.—Operations, 1½ p.m.

King's College Hospital. — Operations, 2 p.m., and on Saturday at 1 p.m.

London Hospital.—Operations, 2 p.m., and on Thursday and Saturday at the same hour.

Great Northern Hospital.—Operations, 2 p.m.

University College Hospital. — Operations, 2 p.m., and on Saturday at the same hour.

Samaritan Free Hospital for Women and Children. — Operations, 2½ p.m.

Royal Institution.—3 p.m. Prof. S. Colvin, "On the Amazons."

Hunterian Society.—7.30 p.m. Annual General Meeting for the Election of Officers.—8 p.m. The Hunterian Oration will be delivered by Mr. A. H. Smee.

Royal Microscopical Society. — 8 p.m. The Annual Meeting for Election of Officers and Council.

Society for the Encouragement of Arts, Manufactures, and Sciences.—Mr. J. Hungerford Pollen, "On the Present Condition of the Art of Wood-carving in England."

Royal College of Surgeons of England. — 4 p.m. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

Sanitary Institute of Great Britain.—8 p.m. Mr. W. H. Michael, "On the Law in Relation to Sanitary Progress," to be followed by a discussion.

Thursday, Feb. 10.

St. George's Hospital.—Operations, 1 p.m.

St. Bartholomew's Hospital.—1½ p.m. Surgical Consultations.

Charing-cross Hospital.—Operations, 2 p.m.

Central London Ophthalmic Hospital. — Operations, 2 p.m., and on Friday at the same hour.

Hospital for Women, Soho-square.—Operations, 2 p.m.

North-West London Hospital.—Operations, 2½ p.m.

Royal Institution.—3 p.m. Mr. Francis Hueffer, "On the Troubadours."

National Hospital for the Paralysed and Epileptic. — 5 p.m. Dr. Buzzard, "On a Case of Disseminated Sclerosis."

Friday, Feb. 11.

St. George's Hospital.—Ophthalmic Operations, 1½ p.m.

St. Thomas's Hospital.—Ophthalmic Operations, 2 p.m.

Royal South London Ophthalmic Hospital.—Operations, 2 p.m.

Royal Institution.—8 p.m. Professor R. S. Ball, "On the Distances of the Stars."

Royal College of Surgeons of England. — 4 p.m. Professor W. K. Parker, "On the Structure of the Skeleton in the Sauropsida."

Clinical Society of London.—8½ p.m. Dr. Sutherland, "On a Case of Chronic Vomiting, in which no food except Koumiss was taken for sixteen months."—Mr. J. W. Teale (Scarborough), "On a Case of Quiescent Scirrhus."—Mr. Heath, "On a Case of Gangrene of the Arm from a Poisoned Wound; Amputation at the Shoulder, and Recovery."—Dr. Whipham, "On a Case of small Round-celled Sarcoma of the Dura Mater, encroaching on the left Temporo-sphenoidal Lobe of the Brain, and producing extensive Softening in its neighbourhood; Absence of Aphasia, the Patient being left-handed."

Saturday, Feb. 12.

Royal Free Hospital.—Operations, 2 p.m.

Royal Institution.—3 p.m. Professor S. Colvin, "On the Amazons."

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Local papers containing reports or news-paragraphs should be marked.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *to be addressed "To the Publisher."*

Uncertified Deaths in the Pottery Districts.

In the mining and pottery districts of Staffordshire the proportion of uncertified causes of death, although recently showing some decline, is still exceedingly high, and a correspondent has recently called our attention to the existence of this evil around Wolstanton. It is specifically stated that registrars in the neighbourhood frequently accept as legal certificates the written statements of unqualified practitioners. As such action is most distinctly contrary to the regulations issued by the Registrar-General and approved by the Local Government, we are scarcely inclined to believe that it prevails to any considerable extent. Registrars, however, may in some instances believe an unqualified or unregistered practitioner to be duly registered, as they are not provided with a copy of the Medical Register, which alone supplies trustworthy information as to medical registration. A registrar is instructed to accept the statement of a medical practitioner with regard to his registration, unless he has good grounds for doubting the accuracy of such statement, in which case it is his duty to apply to the Registrar of the Medical Council for information on the point. With special reference to such a case as that pointed out by our correspondent from Wolstanton, we should advise that whenever it comes to the knowledge of a medical practitioner that a local registrar is accepting as legal certificates written statements issued by unregistered practitioners, the case should be immediately reported to the Registrar-General, who would at once order the rejection of the informal certificates. Without further particulars it would be impossible to hazard an opinion whether the irregular practitioner in question had, by the issue of those certificates, rendered himself liable to prosecution for furnishing a certificate and thus inducing persons to believe him to be a registered medical practitioner. At the same time it must be borne in mind, although false pretension of medical qualification can be punished, there is no law to prevent the most illiterate person from practising medicine, provided he can get patients and there is no pretence of being a duly qualified practitioner. There is, therefore, nothing illegal in the conduct of the "unregistered practitioner" of Burslem, whose written statements of the cause of death are, of course, not accepted as legal certificates by the local registrar. If medical officers of health and medical practitioners would take a stronger interest in this subject of irregular practice and uncertified causes of death, good would undoubtedly result both to the profession and the public.

G. Van Abbott.—Applications for space in the International Medical and Sanitary Exhibition must be made on the official form, which may be had by applying to the Secretary of the Exhibition Committee, Parkes Museum, University College, W.C.

CINCHONA.

THE *Colonies and India*, in its advices from Ceylon, has the following:—"The Calisaya variety of the cinchona tree had been adversely reported upon by Mr. Moens, the superintendent of the Dutch Government plantations in Java, but subsequent reports received from Mr. David Howard, the well-known quinologist, differed entirely from the view taken by the former gentleman, and he pronounced its bark to be superior to that of the renewed Succirubra kind. As the Calisaya had been very extensively planted on the estates, this decision by Mr. Howard had given great satisfaction to the planters. Several extraordinarily large yields of bark were reported to have been obtained from individual trees."

ACUTE RHEUMATISM AS A SEQUENCE OF TONSILLITIS.

To the Editor of THE LANCET.

SIR,—I think the profession ought to be obliged to Dr. Fowler for having brought this subject under their notice. There are many, I am sure, who may have forgotten, or never were aware of the fact, that a large percentage of cases of throat affections are followed by rheumatic fever. I have at present under my care a gentleman whom I saw on the 17th inst., with acute tonsillitis, which disappeared on the 19th inst., and two days afterwards was followed by a tolerably severe attack of acute rheumatism, principally affecting both ankle joints. The interval between the cessation of the throat affection and the commencement of the rheumatism was only two days.

I am, Sir, your obedient servant,
CHARLES H. ROBINSON, M.C.P., &c.
Dublin, Jan. 25th, 1881.

Mr. H. A. Canning.—The subject has not been recently discussed in our columns.

L.R.C.S.I. might refer to the catalogue of the Royal Medical and Chirurgical Society, Berners-street.

Hippocratides (Liverpool).—The late Prof. Francis Boll's physiological papers are to be found in the "Atti della reale Accademia dei Lincei" of Rome, 1875–77, the most considerable of them, that "Sull' Anatomia e Fisiologia della Retina" in the volume for 1877.

THE STEAM-DRAUGHT KETTLE.

To the Editor of THE LANCET.

SIR,—The principle on which a jet of steam may be used to propel air was favourably noticed by you in its application to the simple purpose of an inhaler, which has come into general use in most of our large hospitals.

The extension of the same principle to the homely matter of a bronchitis kettle has been carried out by Maw, Son, and Thompson, and I may recommend this invention as likely to prove useful to the profession.

I am, Sir, yours, &c.,
Savile-row, W., Jan. 25th, 1881. ROBERT LEE.

Surgeon, A.M.D.—We are afraid our correspondent has not read the Warrant very carefully. It does not say anything about pay and allowances. We understand these are at present under the consideration of the authorities.

M. B.—We believe the medical witness is entitled to much the same fees as in England.

Dr. Allan M. Lane Hamilton.—The paper is marked for insertion.

Mr. G. Kingston Barton's paper will appear probably next week.

DISPENSARY PRACTICES.

To the Editor of THE LANCET.

SIR,—Might I crave a few lines in your valuable journal to point out the snares that the so-called provident dispensaries prove in the great majority of instances to young medical men who are tempted, by the bait held out of a snug little income with very little to do for it, to eagerly purchase what on the surface appears to be a most profitable investment, and to earnestly impress upon them the necessity of thoroughly searching the neighbourhood of a dispensary offered for sale, so as to count the number of similar places, and also to place no reliance upon the vendor's books, but to adopt the simple plan of counting the number of patients entering the surgery for a week or two, for by so doing they will, as a rule, soon discover the truth or not of the usual reputed £10 per week receipts.

There is no doubt that cheap, ready-money practices have been great successes in days gone by, but, considering their rapid increase in the last three or four years in localities where the population remains stationary, simply from want of room to increase, the pecuniary result of investing in newly established ones must be apparent to anyone with common sense. My advice and experience, gained from an intimate knowledge—no matter how obtained—of the takings of five or six dispensaries still carried on by purchaser after purchaser, although practically failures, is for a would-be buyer to divide the advertised receipts into halves if he wishes to approximate the real state of affairs, and thus possibly cause him to hesitate before adopting a career that has neither honour nor profit to commend it.

I am, Sir, yours, &c.,
Jan. 23rd, 1881. L.R.C.P. Edin.

SULPHUR IN WOOL AND HAIR.

THE proportion of sulphur in wool and hair (says the *Journal of Applied Science*) is very large, and as they are daily growing, they necessarily draw upon and rob the land of sulphur, its especial constituent. Professor Johnston states that the wool which is grown in Great Britain and Ireland carries off the land every year upwards of four million pounds of sulphur, to supply which would require the addition to the soil of 300,000 tons of gypsum. The hair on the heads of our population carries off nearly half as much as the wool of our sheep. It is not without reason, therefore, that the Chinese collect and employ as a manure the hair shaven every ten days from the heads of their people.

COTTAGE HOSPITALS.

Dr. Stainthorpe of Hexham will be greatly obliged to any medical gentleman sending him a report or any information as to the cost of a four or six room cottage hospital with the necessary appliances and conveniences.

"MEDICAL MEN AND CORONERS' FEES."

To the Editor of THE LANCET.

SIR,—May I once more be allowed to bring before the notice of the profession generally the position of the medical men residing in West Kent relative to the fees for making post-mortems and attending upon inquests. It would appear that the justices of quarter sessions for this division of the county of Kent have decided amongst themselves that we shall make, by the coroner's order, an autopsy, and forward a report of the same; and upon the subject matter of the same an inquest shall be or shall not be held, at the discretion of the coroner. By such action they do away with much importance of the office, and at the same time throw into our hands, for good or for evil, a large amount of unsolicited power, at the same time saving for the county rates a few pounds, though it may be at the cost of some security of life. I will ask, in conclusion, what would or could be expected of a man, even in fair practice, who accepted such terms? The remuneration would not pay for the repair of instruments, and you will be pleased to hear that the majority of the medical men in West Kent have refused, as I have done, to furnish any report under two guineas.

I remain, Sir, yours truly,
Jan. 19th, 1881. CHARLES CHITTENDEN.

ENURESIS.

To the Editor of THE LANCET.

SIR,—May I request the favour of some of your correspondents, through the medium of your valuable journal, giving me advice as to the treatment to be adopted with young boys who habitually wet the bed?

I am, Sir, your obedient servant,
Jan. 29th, 1881. EX FIDE FORTIS.

Dr. F. R. Bernard's communication shall receive attention next week.

Mr. John E. Marsh is thanked.

Mr. J. Ffrench Blake, of Prince's-street, Storey's-gate, desires to caution his professional brethren against the attempts on various shallow pleas at obtaining money by a man of gentlemanly appearance, about fifty-five years of age, above the middle height, of sallow complexion, and with grey hair and beard.

Dr. R. E. Dudgeon.—Declined with thanks.

Lex.—The numbers of THE LANCET for July 12th and 19th and Oct. 11th, 1879, contain articles which will give full information on the subject.

FOREIGN BODY IN THE EAR.

To the Editor of THE LANCET.

SIR,—The following may be of interest to some of your readers:—On the morning of Jan. 28th a man came to me complaining of excruciating pain in the right ear. He said it commenced during the preceding night, when he believed something must have entered his ear while he was asleep. This proved to be the case, as, with the speculum, a dark object, with legs, could be seen, and, with the aid of a forceps and director, I with tolerable ease extracted what turned out to be a cockroach, measuring a little over an inch in length.

I am, Sir, yours truly,
Jan. 31st, 1881. T. G. WHITE, L.R.C.S.I., &c.,
Assistant-Surgeon Tredegar Iron Works.

ANIMAL VACCINE LYMPH.

To the Editor of THE LANCET.

SIR,—You will no doubt recollect my inserting a letter in THE LANCET of 13th Nov. last, saying I would send a supply of calf lymph to any medical applicant on the condition that I was informed as to the result of the use of the lymph. I had 136 applicants, and to each I forwarded lymph. I am pleased to be able to tell you that I have heard of most satisfactory results from many of those, but a large number seem to have forgotten about the promised reply. I am still carrying on the regular vaccination of calves, and although the trouble and expense are both very considerable, I hope to be able to continue until our Government take the matter in hand, when I shall be pleased to retire.

I remain, Sir, yours faithfully,
Manningtree, Jan. 28th, 1881. J. W. COOK, M.D.

HYPODERMIC PELLETS.

DR. H. A. WILSON, of Philadelphia, recommends, for hypodermic injection, the use of soluble compressed pellets, each being composed as follows:—Morphiæ hydrochloratis, ¼ gr.; atropiæ sulphatis, 1-150th gr.; sodii chloridi, ¼ gr. The advantages claimed for these pellets are—(1) their convenient size, (2) they may be used by the mouth if desirable, (3) their certainty of contents and dose, and (4) their certainty and rapidity of action.

CHIAN TURPENTINE IN CANCER.

To the Editor of THE LANCET.

SIR,—I had hoped that some of your readers would in to-day's issue have challenged Dr. Allbutt's opinion as to the value of Chian turpentine, in the case recorded in THE LANCET of January 22nd, p. 155. It was the well-known name of Dr. Clay which made many hope that, at least improbable though it seemed, a remedy had been found for cancer; so when a so-called confirmatory case is adduced by one bearing the name of Allbutt, it ought to bear the strictest investigation. Dr. W. A. Allbutt gives the history of a lady suffering from an extensive suppurating fungoid cancer of the temporal region, infiltrating most extensively surrounding parts, whom he placed under the treatment of Chian turpentine, together with an iron and strychnine mixture. The result was most gratifying: "sleep and appetite returned, and pain vanished." Is it not probable that the strychnia played a more important part than the Chian turpentine? Is it not also probable that, as a coincidence more than a consequence of the treatment, pressure was removed by the extending suppuration or breaking down of a mass near some sensitive nerves, or that the latter were destroyed altogether?

I do not myself think the case can be quoted as a triumph for the Chian turpentine, and I should be glad to elicit the opinion of others upon the subject.

I am, Sir, yours truly,
Jan. 29th, 1881. RICHARD NEALE, M.D. Lond.

PAYMENT OF MEDICAL OFFICERS TO ODDFELLOWS' SOCIETIES.

To the Editor of THE LANCET.

SIR,—In reply to the letter of Mr. F. D. Lys in THE LANCET, Jan. 22nd, respecting the payment of medical officers to Oddfellows' Societies, I beg to say I do not think there is a single lodge in London, either Oddfellows or Foresters, that pays its medical officer more than a shilling per quarter per member, but, on the contrary, I regret to say there are lodges which pay only ninepence per member for medical attendance.

I have over 1500 men in my several clubs, all of which pay me one shilling per member, and that sum they paid my late father, who held these various clubs for over twenty years. The medical man is expected to visit all members (unable to attend at the doctor's house) within three miles radius from the house where the lodge or court is held, and when the lodge-house is situated, as is not unfrequently the case, a mile or two from your own, the distance is much increased.

The rules of most benefit societies state that "no member is entitled to receive sick benefit whose illness is produced by his own indiscretion," and therefore is not eligible to medical attendance otherwise than as a private patient, and this rule we generally enforce or send the member to one of the metropolitan hospitals. The remuneration of one shilling per quarter is preposterously small, but as there are plenty of medical men ready and willing to accept this small sum, it will have to remain until there is some "unity" amongst us and a general demand for higher fees. Excepting for the fact that an amount of private practice is derived from attendance upon the wives and families of some of the members, club practice would be unbearable, the amount of remuneration for services given not permitting of analysis.

I am, Sir, yours faithfully,
ROBERT A. H. HART, L.S.A. Lond.
Stone's-end House, Southwark, Jan. 26th, 1881.

AN APPEAL.

To the Editor of THE LANCET.

SIR,—Your columns I know are always open on behalf of distressed members of our profession and their families, and I venture to bring the case of Mrs. Morris, of Stratford-on-Avon, to the notice of those of your readers who are benevolently inclined as one deserving of help.

Mrs. Morris is the widow of a medical man who practised at Deddington, Oxon, and met with his death eight or more years ago by a fall from his horse at an early age, leaving his wife and five children almost without provision. One of the sons was elected to the Medical Benevolent College at Epsom, but was removed in consequence of bad health three years ago, since which time he has been confined to bed and afflicted with abscesses, having at the present time sixteen or more, with no prospect of recovery. Mrs. Morris's total income is under £70 a year. I have been able to collect a small sum from a few of my patients for her, but the great tax caused by the invalid boy has brought the mother into difficulties, and she will be sincerely grateful for any help the profession may extend towards her.

Donations forwarded to me shall have due acknowledgment.

I am, Sir, yours very truly,
Ewell, Surrey, Jan. 31st, 1881. GEO. R. BARNES.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Tatham, Salford; Mr. Craigie, London; Mr. Rimmington, Bradford; Dr. Cook, Manningtree; Mrs. Prætorius; Dr. B. Squire, London; Mr. E. Owen, London; Mr. Ainley; Dr. Wahltuch, Manchester; Mr. Canning; Mr. Wallis; Mr. Marsh, Barrow-in-Furness; Dr. Dabbs, London; Dr. Stainthorpe; Mr. J. F. Blake, London; Dr. Neale, London; Dr. Bantock, London; Mr. W. Turner, Glasgow; Mr. Post, Berout; Mr. F. Godrich, London; Mr. White, Tredegar; Mr. Reeves, London; Mr. Bell, Tynemouth; Dr. H. Sutherland, London; Dr. Saundby; Mr. G. R. Barnes, Ewell; Mr. Clegg, Liverpool; Dr. S. E. B. Brown, Kashmir; Mr. C. Young, Chilton-Polden; Mrs. Sole, Devonport; Mr. A. L. Hamilton, New York; Dr. F. Evans, Cardiff; Dr. Latham, Cambridge; Dr. Dudgeon, London; Dr. Stephens, Liverpool; Mr. G. Pollock, London; Mr. J. K. Barton, London; Mr. Ball; Dr. Fisher, Rathmullen; Dr. Steventon; Mr. Brookes, Wellington; Mr. Taylor; Mr. Gick, Dublin; Dr. F. Bernard, Stockwell; Mr. Bowring, London; Mr. Boyle, Tenby; Mr. H. T. Wood, London; Dr. Willis, Monmouth; Messrs. Squire, Fox, and Co.; Dr. Moritz, Manchester; Dr. Evatt, Woolwich; Mr. E. Morgan, London; Sussex; W. C. H.; Perplexed; L.R.C.S.I.; The Secretary of the National Association; Ex Fide Fortis; The Earl of Kimberley; &c., &c.

LETTERS, *each with enclosure*, are also acknowledged from—Mr. Toyne, Sheffield; Mr. Leman, Chipping Sodbury; Dr. Tinley; Dr. Charteris, Arcachon; Mr. Purcell, Feakle; Dr. C. Reid, London; Mr. Jones, Lowyn; Mr. Croft, Church Gresley; Dr. Lyon; Mr. Hyatt, Shipton Mallet; Mr. F. Jordan; Dr. Saffern, Birmingham; Mr. Walker, Fulbourne; Mr. Siccama, Portland; Mr. Maclehose, Glasgow; Dr. Ridge, Enfield; Mr. Drefus, Strasburg; Mr. Chadwick, Islington; Mr. Chestnut, Tralee; Mr. Clacker, New York; Mr. Bisdee, Cleveland; Mr. Watts, London; Mr. Hyslop, Church Stretton; Dr. Lovell, Bradford-on-Avon; Mr. Granger, Bristol; Mr. Howlett, Westgate-on-Sea; Mr. Shepherd, Liscard; Messrs. Oliver and Boyd, Edinburgh; Dr. Philpot, Poole; Dr. Jacob, Leeds; Mr. De Frane, Aylesbury; K. K.; Alpha, Durham; Surgeon, Great Grimsby; Fides, Yaxley; Dr., Liverpool; Student, Notting-hill; M.D., Camborne; Sigma; Cinchonin; Medicus, Roath; Surgeon, Halifax; J. M., Cirencester; P. F.; M.D., Liverpool; W. S. N.; F.R.C.S.; Delta; Surgeon, Camden-town; Medicus, Sheffield; Physician, Eccleshall; Medicus, Killamarsh; Benedict; Q. X. Z.; R., Brighton; D. S.; Z.; E. J.; G. B., Newport; Medicus, Hitchin; J. K. M. D.; &c., &c.

Essex Telegraph, Estates Roll, North Wales Guardian, Woodhall and Clafflin's Journal, Coffee Public-house News, Education, Western Daily Mercury, The Specialist, Tenby Observer, Herald of Health, Charity Record, Indian Medical Gazette, &c., have been received.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year	£1 12 6	Six Months	£0 16 8
TO CHINA AND INDIA		One Year,	1 16 10
TO THE COLONIES AND UNITED STATES		Ditto,	1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

The above Scale of Charges is arranged upon the basis of the classification adopted in the Index.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements (on page 2), which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom.

The postal arrangements relating to the distribution of THE LANCET will be considered from time to time in the interests of subscribers.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

Annual Address

TO THE

OBSTETRICAL SOCIETY OF LONDON.

Delivered February 2nd, 1881,

By W. S. PLAYFAIR, M.D., F.R.C.P.,

PRESIDENT OF THE SOCIETY.

GENTLEMEN,—It is again my pleasing duty to congratulate the Society on its continuous prosperity. Since our last annual meeting we have elected 40 new Fellows, while we have lost 37 by death and resignation. The Society now numbers 749 Fellows.

Outside the special work of the Society there are two matters worthy of your notice, since they have to do with the general progress of the department of medical science in which we are specially interested. One of these is the representation of Obstetrics on the General Medical Council. The attention of the profession has more than once been called to the strange fact, that in what is practically the Parliament of our profession, which undoubtedly ought therefore to represent all branches of medical practice equally, there has hitherto not been a single member who practised obstetrics, and who might claim to speak with authority when subjects connected with it were discussed. The result of this glaring defect has been that obstetrical questions have been very inadequately treated; not, I am sure, purposely, but from a very natural ignorance of their merits. When we reflect that obstetrics form a large and important part of the daily work of an immense majority of the medical profession, we are surely justified in maintaining that there should be some members of the Medical Council who know something about the matters they are discussing. During the past year a vacancy occurred in the Medical Council by the death of Dr. Hudson, and since the nomination was vested in the Crown, your Council empowered me to head a deputation to the Lord President of the Council for the purpose of pointing out to him the facts I have alluded to. Unfortunately he was unable to receive us, and I therefore addressed to him a petition on behalf of the Council, a similar course having been adopted by the Obstetrical Society of Dublin. No definite decision has yet been announced, but there is good reason to hope that our memorial will lead to the nomination of an eminent obstetrician, whose name is of itself a sufficient guarantee that the interests of obstetrics will in future be properly represented in the deliberations of the General Medical Council.

Another equally glaring and even less defensible anomaly was the fact that in the examination for the membership of the Royal College of Surgeons obstetrics had no place. As the membership of the College forms the most common of all the qualifications for general practice, that must be admitted to have been not only a defect, but an absurdity. That the College should give its *imprimatur* every year to the qualification to practise of hundreds of men, without the slightest attempt to satisfy itself that they possessed the most elementary knowledge of one of the most anxious and responsible branches of their profession, may fairly be said to have been something even worse than an absurdity. I am happy to be able to announce to you that this reprehensible state of things is about to be put an end to, the Council of the College having decided that on and after the 1st of January, 1882, the candidates for the membership shall be examined in midwifery as well as in surgery and medicine.

The past year has certainly been not less fertile than its predecessors in the amount of work which the Society has accomplished. Not only have the meetings been well attended, but the discussions have often been lively and interesting. The custom which the Society has adopted from the first of reporting at length in our Transactions the discussions which have followed the reading of papers has always seemed to me to be a very valuable one. By this means the varying opinions entertained on any special subject are permanently recorded, and much interesting information may be gathered from them which would otherwise never be obtained and be entirely lost. I am conscious of having myself gained, from time to time, important knowledge from this source.

At our first meeting we had an elaborate statistical record by Dr. Champneys on the site, character, and best mode of relieving the pain in uterine cancer. The deductions made by him from fifty carefully observed cases differ somewhat from the opinions which have been generally entertained. In his statement as many of the patients affected were between thirty and forty as between forty and fifty years of age. This is certainly contrary to general experience, and Dr. Champneys' results were probably to some extent accidental, in consequence of the comparatively small number of cases observed. Thus, for example, out of 108 cases carefully noted by Scanzoni, sixty occurred between forty and fifty years of age, and only thirty-five between thirty and forty; while out of 112 cases recorded by Emmett forty-two occurred between forty and fifty years, thirty only between thirty and forty. It is to be hoped that Dr. Champneys will extend his observations on this disease to other points even more important than that of pain. I know of few topics in connexion with gynæcology in which more promising results are likely to be obtained by advancing knowledge than in that of uterine cancer. To point to one subject in connexion with its etiology only, the statement made by Emmett, and supported by Thomas in his latest edition, that all cases of epithelioma have their origin in laceration of the cervix, requires careful study; since, if this be so, prevention is not altogether beyond our reach. Then, as regards treatment, we are already far in advance of the gynæcologists of only a few years ago in dealing with this most deadly disease; and the very generally entertained opinion of pathologists of the present day as to its essentially local origin, strongly encourages us to study the means at our disposal for eradicating it before it has made such ravages in the affected part as to render all interference useless. This subject has already engaged the attention of the Society in a paper by Dr. Wynn Williams on the local treatment of cancer by bromine. In the removal of epitheliomatous growths of the cervix by the knife and galvano-caustic, after the plan recommended more especially by Marion Sims, I have, from time to time, obtained most encouraging results, and the possibility of dealing with such growths much earlier and more effectually than has hitherto been the case should obtain our earnest attention. Then, again, there is the very important subject of the total extirpation of the uterus in early stages of malignant disease, a question which calls for the most serious study, and which, strangely enough, has not been yet taken up in this country, the cradle though it be of abdominal surgery. Although the originator of the method, Professor Freund of Breslau, has operated fourteen times with five recoveries, and his example has been followed by many of the leading surgeons in Germany, I have only heard of one or two unsuccessful operations in this country, and the subject has not yet been brought under the notice of this or any other Society. Probably the extreme complexity of Freund's operation may account for the small degree of favour it has as yet received in Great Britain. No one can doubt, however, that in these days, in which uterine symptoms receive much earlier attention than was formerly the case, malignant disease of the uterus may very frequently be detected before it has spread to any of the surrounding textures, in which it is strictly limited to the uterus, and in which that organ is still perfectly mobile. Perhaps there is no organ in the body, except possibly the mamma, in which total extirpation promises more successful results, if only a comparatively simple operation could be devised. It is worthy of note that that great obstetrician, Dr. Blundell, fully recognised this fact long before the days of abdominal surgery had commenced, and actually removed the uterus in four cases from the vagina, and I am by no means certain that some modification of the plan he adopted may not yet be found easier than Freund's operation. As a matter of fact, Professor Billroth of Vienna has, during the past year, resorted in several cases, in some successfully, to a modification of Blundell's operation, which he maintains to be far more easy and satisfactory than Freund's. Be this as it may, I trust I may be pardoned for specially directing the attention of those of our Fellows who are experts in abdominal surgery to this topic, in the hope that they may, ere long, bring it under the notice of the Society.

At the April meeting Mr. Lawson Tait read a paper, which may be here mentioned as it deals with an interesting and hitherto little studied point in abdominal surgery, on "The Axial Rotation of Ovarian Tumours leading to their death." It not only added to our knowledge of the accidents attending ovarian disease, but led to an important discussion, in which many of our prominent ovariotomists took part, which the Fellows doubtless remember. Mr. Tait's ingenious theory as to the cause of this accident being the alternate filling and emptying of the rectum, although not generally admitted to be correct, struck me as very interesting. There can be no doubt that the presence of this viscus and its varying dimensions in the pelvis plays an important part both in obstetrics and gynæcology, which has not been sufficiently studied, although its influence has been recognised by Sir James Simpson and other writers. I can imagine a valuable paper being composed on this subject.

Another of the burning questions of the day in connexion with abdominal surgery occupied the Society on the reading of a paper by Dr. Godson, recording a successful laparotomy performed by Mr. Spencer Wells, and a very important paper by Mr. Knowsley Thornton on "The Removal of Uterine Fibroids by Laparotomy," and certainly no more interesting subjects could come under discussion. We had the advantage of hearing the views of many well qualified to speak on this point. No one can doubt that a great future lies before this operation, and the brilliant results of the antiseptic method, properly and carefully carried out, in abdominal surgery, certainly render the chances of success much greater than they otherwise would be. While I fully admit that the removal of uterine fibroids by hysterectomy, in properly selected cases, is a perfectly legitimate procedure, I cannot think, with some who took part in the debate, either that this operation can be talked of as on a level with ovariotomy, or that it is ever likely to become so; and I am inclined to hold that this is a subject in which the brilliant successes of ovariotomy, and the operative skill resulting from them, are perhaps a little apt to warp our judgment. In diseases such as ovarian tumour, uterine cancer, and the like, which, if left to run their natural course, must, of necessity, ere long prove fatal, no difficulties and no dangers need stand in the way of an attempt at radical cure. In diseases which may embitter life from suffering, but which probably may not kill at all, or only after many long years, the resort to an operation of such gravity should, I venture to submit, stand on an entirely different footing. In some cases it is undoubtedly legitimate, and in one of Mr. Thornton's cases which I saw with him I myself counselled the patient to undergo the operation; but the momentous decision is not to be lightly made, and much study of the natural progress of fibromas is still required before one can feel justified in arriving at very positive conclusions on this point. It is to be remembered, too, that in the cases of fibroid in which life is most often imperilled—those accompanied by profuse and exhausting hæmorrhage,—there is a fair prospect of material benefit, if not of complete cure, from the far less serious and less difficult operation of spaying, the indications for which, like those of laparotomy, are still *sub judice*. I have ventured to make these observations, because I fear there is a tendency to resort somewhat rashly to this grave procedure, which time and greater experience will doubtless modify. I am well aware that in the hands of such experienced and careful operators as Mr. Thornton there is no risk of the kind I have indicated, but I have elsewhere known of more than one case in which laparotomy has been recommended where, in my judgment, it was by no means imperative, and in which the tumour in no way imperilled the patient's life, and even interfered very little with her comfort. A word of caution may, I trust, therefore be considered to be not altogether out of place.

The June and July meetings were pretty fully occupied by a paper by Dr. Graily Hewitt, on Uterine Flexions and by the discussion which followed it; and although it was not a formal debate on a settled subject, such as that which we had last year on the Use of the Forceps, it was so animated and prolonged that it practically assumed the dimensions of one. I have heard it said that we have had somewhat too much of flexions in our Society, and that it was time the subject was dropped. I cannot myself quite endorse that view, for, doubtless in great measure owing to Dr. Hewitt's persistent advocacy of his own theory of uterine disease, the profession and the public have got a rooted hold of the subject; and whenever uterine symptoms exist, not well understood, we are now told that the womb is probably displaced. It is, I think, greatly to be regretted that in gynæcological practice there is this tendency to run into extremes and fix attention too exclusively on one class of disease only, whether it be what is called an ulcerated womb, a displaced organ, or, what is likely to be the gynæcological lesion of the future, if we may believe our American brethren, a lacerated cervix. This being so, it cannot be unimportant that the subject should be thoroughly discussed in all its bearings; and I trust, therefore, that the time we devoted to it may prove to have been well spent. Personally, although I dare say my friend Dr. Hewitt may consider me a somewhat lukewarm follower, I owe it to him to state that I attach much greater importance to flexions than I did some years ago, and this has followed from a study of his views and opinions. Indeed, I am at a loss to understand how anyone who sees much uterine disease can possibly doubt the extraordinary effects produced by flexions, or the equally extraordinary results which follow judicious mechanical treatment. This is, however, a very different thing from admitting Dr. Hewitt's theory that all uterine disease is caused by flexions—a view which not only leads, as I venture to think, to mistaken practice, but causes those who adopt it to overlook many conditions of primary importance. I trust these remarks may not be misunderstood; but it seems to me, above all things, necessary in this special department of practice that we should hold broad views, and not let ourselves be led into a narrow groove, the following of which, by men less able than Dr. Hewitt himself, may lead to much that is strongly to be deprecated. In the address which I delivered at the Obstetric Section of the British Medical Association at Cambridge in August last, I ventured to point out that the reason why gynæcological practice was in some respects so uncertain was the want of accurate pathological knowledge of the condition of the parts affected; a want for which we are not altogether to blame, since it results partly from the comparatively short time that has elapsed since the diseases of women became the subject of special study, and partly from the difficulties that surround the pathological investigation of the diseased organs. Since writing the above I have had the pleasure of reading in the new edition of our Honorary Fellow, Dr. T. Gaillard Thomas's admirable work on the Diseases of Women, some remarks which so strongly corroborate the observations I have made on this point, that I shall venture to quote them. "Nothing," he says, "more decidedly retards the progress of gynæcology, lowers it as a special study in the eyes of its sister departments, and fans the dying flame of a prejudice with which it has been successfully able to contend only during the past half century, than the unsettled state of uterine pathology. In general medicine, in surgery, and in all other special departments, the study of pathology is made the keystone of the arch which supports them; and observers seem willing to agree as to fixed principles concerning it. In gynæcology the whole subject presents the melancholy aspect of uncertainty and dissension. Many of its votaries, instead of taking broad and strong views, become the partisans of some special dogma or theory, which is warmly attacked by others who hold some view equally narrow, incomprehensive, and exclusive." Perhaps this unhappy state of things is not unnatural in a comparatively new study, but the more frankly we recognise the shortcomings of our department, the sooner shall we get rid of them; and we have had some excellent work before us, such as in the account of the "Pathological Anatomy of Erosions of the Cervix Uteri," and on the "Histology of Endometritis," by our honorary secretary, Dr. Galabin, which shows that considerable attention is now being paid to this topic.

There are many other papers of importance besides those I have referred to, on which, did time allow, I might very properly remark, but I have, I fear, already trespassed too long on your patience to justify my referring to them. I must, however, make a passing allusion to Dr. Priestley's interesting paper "On the Induction of Abortion as a Therapeutic Measure," since it is the first attempt, so far as I know, to systematise the causes which may justify the practitioner in resorting to this distasteful procedure, and to lay down laws for his guidance. It is surely time that a subject such as this should be fairly grappled with, and I am sure we must all agree in thinking that Dr. Priestley not only did us a service in bringing it before us, but that he has laid down a series of very judicious rules in regard to it, which, if strictly attended to, may prevent the abuse of this procedure. In other countries the production of criminal abortion has become, we are told, almost a system, and is practised with unblushing openness, leading, as it may well do, to most disastrous results. Fortunately for us, nothing of the kind exists here, at least not to any appreciable extent, and I trust that Dr. Priestley's paper may, by the safeguards it has laid down, assist in preventing this most pernicious practice ever becoming prevalent amongst us.

The remainder of the address was chiefly devoted to obituary notices of deceased Fellows.

Clinical Lecture

ON THE

DIAGNOSIS & TREATMENT OF RINGWORM.

Delivered at St. Mary's Hospital Medical School,

By MALCOLM MORRIS, F.R.C.S. EDIN.,
JOINT LECTURER ON DERMATOLOGY.

(Concluded from page 166.)

NEXT I desire to call your attention to the practical part of our subject—namely, the treatment. Let us consider for a moment what are the fundamental points to be held in view to guide us. The disease is an eczema produced by a local cause, which cause it must be our business to remove. In doing this, however, we must not aggravate the eczema, but, on the contrary, endeavour to cure it at the same time. The essence of the treatment is the destruction or removal of the fungus, for until that is done the disease cannot get well.

The question then is, How is this best effected? If the disease is on a non-hairy part of the body, be it acute or chronic, it is quickly cured, and for the following reason:—The fungus grows in the layers of the epidermis, and mechanically or chemically can therefore be either removed or destroyed.

If, for example, strong blistering fluid be applied to a patch of ringworm of the body, a bleb is raised in which fungus can be found; in this way much, and sometimes all, is removed mechanically; or if one of the remedies known as parasiticides be well rubbed into the patch, the fungus is soon reached and destroyed. But I can assure you it is quite another matter if a hairy part such as the scalp is affected. It is true in some recent cases cure may be effected by one application just as if the part were non-hairy. But in these cases the fungus, from some unknown cause, has not been able or has not had time enough to penetrate into the follicle. These are the cases that win for quack remedies the credit of performing marvellous cures. I have no hesitation in saying that it is a really difficult thing to cure a well established ringworm of the scalp, in which abundance of fungus is to be seen around the roots of the extracted hairs. The first question of importance to consider is whether there is any means at our disposal for the mechanical removal of the fungus when it is situated deeply in the hair-follicle. Two methods of epilation are advocated—the one by forceps, and the other by the calotte. This latter is a pitch plaster which, having been placed firmly on the head, and allowed to dry, is then forcibly torn off. Naturally this procedure is very painful, and, besides, it does more than is required, tearing out sound with diseased hairs. In addition, as it has the same disadvantages as simple epilation, which I am about to mention, I do not advise you to adopt it. Some authorities very strongly advocate epilation by forceps, affirming that ringworm of the scalp cannot be cured without it. Others think it useless. For myself I am inclined to take a position midway between these opinions, and say that in early acute patches, where only a limited number of hairs are affected and there is a prospect of extracting the root when the hairs are removed, the operation may be performed with advantage. When, on the other hand, the disease is of old-standing, and the hairs break easily on being touched, I think it is worse than valueless to epilate. Even when the mischief is localised to a small patch and is chronic I do not adopt it. It is easy to understand that if you succeed in extracting the stump, root and all, you must leave much fungus behind in the depths of the follicle, and you have not advanced your cure one iota, since it is only a question of time for the fungus to rise again to the surface. So much, then, for the mechanical removal. I now pass to the chemical mode of destruction. Chemicals such as sulphur, mercury, tar, and iodine act in two ways. First, in consequence of certain properties which they contain that are antagonistic to the growth and also to the very life of vegetable organisms, they are used as and denominated parasiticides; and, secondly, they are employed to excite more or less inflammation in the skin to which they are applied.

I cannot pretend in a brief lecture to be able to describe the numberless remedies that are grouped under the name of parasiticides; and even if I could, no useful purpose would be gained. They all seem to be of about equal value, and it matters little whether you select sulphur, mercury, tar, tar and iodine, or chrysophanic acid, and each in turn has had its supporters and its detractors. But, of course, there is one exception—viz., carbolic acid, a drug that has held its own in spite of all opposition. The value of carbolic acid as an antiseptic and a destroyer of low vegetable organisms is, I am sure, too well known to you through the brilliant researches and results of Professor Lister to need any introduction from me. Here then seems to be our sheet anchor. A powerful well-recognised antiseptic would soon destroy our enemy, and some eminent authorities recommend it as one of the best of remedies. For instance, Dr. Alder Smith, before quoted, uses equal parts of carbolic acid and glycerin, the latter to carry the antiseptic to the bottom of the follicle. I would at once recommend this to you as the remedy to use had I not found in practice that it does not answer, and I have my own theory to account for the indifferent results. I do not think that glycerin does penetrate sufficiently deep into the follicle, and carbolic acid in strong enough proportions to be of use is a severe local irritant, to say nothing of the risk of constitutional poisoning, which occasionally occurs when this agent is persistently applied to a tender skin. We want a *parasiticide*, but we do not want an *irritant*. And this leads me to a second effect, which is another objection, in my mind, to the employment of these drugs. They excite more or less inflammation in the skin. This is what, as far as I can judge, all authorities on ringworm have hitherto insisted upon as the essential means of cure. No one has, however, stated it so boldly and argued it with so much skill as Dr. Alder Smith in the article mentioned. He even advocated going to the length of producing artificial kerion, in order that nature may be copied, and the fungus be destroyed by a severe inflammatory process. This he does by the application of croton oil. He says, "Croton oil is the best irritant for causing this inflammatory condition."

My experience has taught me to differ entirely from Dr. Smith in the desirability of producing any inflammation; on the contrary, I think inflammation should be avoided. We should rather turn our attention to remedies that are *gentle* in their action. I am confident that many old-standing cases of ringworm are the result of *over-treatment*—that is to say, a chronic eczema is produced by the remedies, and kept up for months and years, while the fungus all the time exists undisturbed. Of late, with the view of carrying theory into practice, I have been trying some combinations of drugs, which I will now briefly describe.

Seeking for an antiseptic or parasiticide which would be less irritating than carbolic aid, and without its dangers, I have been led to try thymol and some other similar drugs. Thymol, a camphoraceous body belonging to the phenol series of aromatic compounds, is present in small quantities in oil of thyme, but is obtained chiefly from the seeds of the Ptychotis ajowam. It is a powerful antiseptic, being, according to Bucholz,[1] eight to ten times as efficient as carbolic acid in preventing the development of bacteria. It is not nearly so great an irritant to the skin when applied locally, and there is no risk of constitutional poisoning. Menthol is a somewhat similar substance obtained from Japanese oil of peppermint. That it is not far inferior to thymol as an antiseptic, I think you will see from the following experiments. From its power of relieving neuralgia when placed on the skin, and the numbness its application produces, it might be used with good results instead of thymol when there is much tenderness or irritation.
